Protection of those species whose numbers are not yet reduced below a critical point would doubtless be possible and adequate. Conservation of beavers has been successful in such cases. Nature distinctly favors some of the species through their practically inaccessible habitats, or their self-protective instincts. It is evident that protective legislation would consequently vary with the species and with the conditions of its existence in particular localities. Where one mammal may require a five-year closed season, another may need protection during the breeding season only, and for still another, protection may be altogether unnecessary at present.

There is further reason for paying heed to these elements of our fauna. The fact that man is the dominant species does not justify his wanton extermination of any members of the living world around him. It has taken nature geologic ages to evolve these animals, and it is our duty to be considerate in our dealings with subordinate forms of life.

There is no resurrection or recovery of an extinct species, and it is not merely that here and there one species out of many is threatened, but that whole genera, families and orders are in danger.

Dr. Mitchell in a recent number of *SCIENCE*<sup>6</sup> has forcibly called attention to a number of facts, full of sinister warning to those who dislike to stand by and see the careless destruction of our native fauna. Allow me to quote again for the sake of emphasis:

Each generation is the guardian of the existing resources of the world; it has come into a great inheritance, but only as a trustee.

In the opinion of the writer the intrinsic interest and the humanitarian arguments, as well as the economic one, emphasize strongly the desirability for wise attention to this lesser problem of the fur-bearing mammals, none the less than to the careful conservation of all

the rest of the wild life yet remaining at our disposal.

#### THE WRITINGS OF WILLIAM G. SUMNER

TO THE EDITOR OF *SCIENCE*: A little over a year ago the Yale University Press published a collection of essays by the late Professor William Graham Sumner. It is now proposed to publish another volume to be called "Earth Hunger and Other Essays," during the fall of 1913 or a little later. In connection with this enterprise, I wish, as editor, to bespeak your assistance.

It is desired, in this proposed volume, to collect (aside from more extended matter) all of Professor Sumner's shorter publications. Many of his best and most characteristic utterances were brief articles, struck off on occasion, and widely scattered in newspapers and magazines. We have little trouble in finding his longer articles, but it is difficult to locate many a short and vivid fragment. Since the other volume was issued, not a few suggestions have come to our ears to the effect that another time we should not overlook this or that pregnant utterance—some striking thing which has riveted the attention of our courteous censor, and which he would like to have at hand. Sometimes such a constructive critic can not remember just where or when he has seen such an article, and suggests vaguely that it was "in the papers," or "in one of the weeklies."

Now we want all these scattered materials, and it has occurred to me that suggestions might be forthcoming as to their whereabouts, if our present effort to make a final and exhaustive collection of Sumneriana were announced to your readers. We should be glad to examine any materials that might come within the scope of the proposed volume, and to receive any suggestions, however vague, as to utterances, brief or extended, from the pen of Professor Sumner. Materials sent me in care of the Yale University Press will be acknowledged and promptly returned after examination.

<sup>6</sup> 1912, p. 353 and following.

As this volume will, in all probability, close the collection of Sumner's printed works in the line of essays and short pieces, those who can assist us in securing available materials will confer a substantial favor.

ALBERT G. KELLER

#### LEST WE FORGET

TO THE EDITOR OF SCIENCE: The new administration, with democratic majorities in both house and senate, was entrusted with power in the belief that it will be responsive to the needs and demands of the people. But in the various programs suggested for the amelioration of present-day abuses nowhere has any mention been made of the early adoption of the metric system as an obligatory system in this country, accompanied by the destruction of the old systems. The writer has reached that second childhood when, at the request of his children for aid in doing their "sums," he must again wade through the chapters in the arithmetic devoted to the various tables of hodge-podge units, and he realizes, as never before, the truth of the statement that the whole thing is "a wickedly brain-destroying piece of bondage under which we suffer."

To see young minds eager for the study of live subjects forced to work hundreds of useless problems in this treadmill of heterogeneous dead and dying units is enough to rouse the ire of any one against those selfish interests which are blocking the way of reform.

When we consider the situation candidly we must acknowledge that the matter is one of extreme importance. A great part of the under-weight and false-measure frauds are directly due to our confused system of units, and on the adoption of the metric system under such protective regulations as are in force in Germany, for example, a tremendous saving would be effected in the cost of living to wage earners especially. Can not all scientists, who understand so well the merits of the metric system, rouse themselves and make a strong effort to have the bill passed which has been before congress for many years, backed by the various government bureaus

and reform leagues? It took thirty years to obtain the parcel post; must we wait that long? Or can we not make a long pull, a strong pull, and a pull all together, and get it through next winter?

CHAPEL HILL

#### TO WHOM IS THE ACADEMIC COSTUME WORTH WHILE?

TO THE EDITOR OF SCIENCE: Even if we disagree on the use of medieval costume in modern institutions as a matter of academic good taste, may we not set our faces against any participation in the decision by a commercial propaganda aiming to extract large profits from members of an underpaid profession?

T.

#### SCIENTIFIC BOOKS

*Cambrian Brachiopoda.* By CHARLES D. WALCOTT. Monograph U. S. Geological Survey, Vol. 51. Part I., Text. Part II., Plates. 1912. Pp. 872, 76 text figures, 104 plates.

The dominating impression which this extraordinary work leaves upon one who runs a hasty eye over its pages and luxurious plates, is that of the marvelous industry and enthusiasm of its author. If the paleontological genius who controlled these facts here assembled had nothing else to do, the wonder might be less. But amid the responsibilities of a great office and affairs of widest scientific concern, the writer of this book seems to let no minutes go to waste which can be made to forward his expositions of that field in paleontology of which he has long been the most effective illuminator.

Here are two quarto volumes devoted, by title at least, exclusively to the Brachiopods of the Cambrian fauna. Nearly twenty years ago students of this multitudinous, variant group of animals believed the sum of knowledge concerning them enough to justify a treatise on the broad lines of their generic characters, so Professor James Hall and his assistant published two big quartos on this subject, therein searching out every nook and cranny that might afford traits of generic sig-

nificance in all known or available forms of these creatures. Even to such a study the Cambrian brachiopods cut a very modest figure in paleontology. Specimens were few, their structures were obscure, and hence their relations were difficult to interpret; most of the available material was poorly preserved and, as a whole, they played a dubious rôle in the generic history of the entire class as well as in the total of the Cambrian fauna.

In this new book the student may scan 104 crowded plates of the Cambrian Brachiopods, bearing from 3,000 to 4,000 figures, and after the first bewilderment has passed, he comes to the realization that at last a definite progress has been made in the census, the analysis and estimate of the morphology and biologic worth of these early and hence most significant organisms.

The columns of SCIENCE are hardly the place for a critical study of Dr. Walcott's results or a measurement of their advance over previous knowledge. The author's publications on various aspects of the Cambrian fauna have been as startling as rifle shots and as effective in opening our eyes to the unexpected development of life within this field. With this book before us, inherited and acquired notions of the paucity of life in this "primordial" age of the earth are forever swept aside. The present panorama of the Cambrian Brachiopod fauna is simple in aspect but numerically comparable to the brachiopod element in any later geological age. At any rate here are listed about six hundred species and only the census taker for the class would dare say how far any single subsequent period has overpassed that number. As against their successors in the later rocks they lack in diversity of expression, for these are simple, sturdy, coherent types, largely devoid of the sudden and fugitive variations which accompany the tachygenic, arrested and declining stages in succeeding faunas. The author had the courage, years ago, to break the restraints of geography and politics and to content himself with nothing less than the earth for his field. Above a thousand localities are cited in his lists here and it is the Cambrian terrane of the

world which the author has been enabled to reach through many direct and indirect avenues; yet the substantial basis of the work is his own discoveries in regions of his own exploiting.

It is probably not the proper business of a notice of this work to analyze the part it has played in the ecology of the author, but the author is, for the moment, impersonal as is any author who may have achieved so tremendous an addition to the details of scientific fact. These kernels of knowledge are not easy to assimilate, they seem to go hard with even the spiritually minded seeker after all truth, and one may be disposed to wonder if the joy of discovery, the sense of contribution, the rebound of satisfaction which comes with each new determination of fact, is not the great reward in such achievement. But here let us go slowly. If the whole truth were to be known and the real underlying genius of life could be indisputably portrayed, I presume the difference between *Lingulella cuneola* and *Lingulella desiderata* might prove to be as vital in the Grand Plan and to the Sum of Happiness, as the winning or losing of a congressional appropriation for a museum of industry. Nevertheless, no man can be so deeply conscious of the worth of such a work as the man who did it; no one can appreciate so well the broader bearings of such a monumental increase of human knowledge. Fortunately it is not of the sort that has to be applied to meet human expedencies. Hence its glorious justification.

The greater volume of the text of this work is given over to the descriptions of the species, but there are preliminary chapters of broader scope, among them none more suggestive than the analysis of differential shell structures. Following Beecher's broader classification of the brachiopods, based on the characters of the pedicle passage, *Atremata*, *Neotremata* and *Protremata* (the first and second corresponding to Huxley's *Inarticulata*, and the third to the *Articulata*) the majority of species and genera are *Atremata*, and they, with the *Neotremata*, are as much in excess of the rest here as they are over-

passed by the higher *Protremata* in the later faunas. This is as it should be, for they are diverse expressions of the simplest brachiopod structure. Broadly speaking, regardless of their multitude, the species of the major divisions are all oboloid or linguloid in outline. The disk of the oboloids has been oft repeated in the geological history of the brachiopods, though it has served to mask widely distinct genera; but as for the sharpened *Lingula*-form—it would seem there was a divinity that shaped its end, for it has come down to this day without much change, just enough in fact to let us say that no true *Lingula* existed in Paleozoic time, hard as it might be to prove it. One can not restrain surprise at the beauty of retention of much of this material, the perfection of shell structure, of pallial venation, ovarian and muscular impressions, set forth on the plates by extremely effective mechanical processes of illustration. The quality of this illustration is most admirable, and it would seem that the personal error of portraiture has been here reduced to its lowest terms.

Should one, on cursory examination of this host of newcomers in paleontology, wondering over their relationships, their phylogeny and precedence, venture to whisper to himself of *Orusia eurekaensis* or *Otusia utahensis*—who was its father? who was its mother? had it a sister? had it a brother?—these wisely suppressed inquiries are answered on page 317, which graphically sets forth the presumed derivative relations of the genera discussed. This page is exceedingly instructive. Beecher found the brachiopod radicle best expressed in the Cambrian genus *Paterina*, and his proposition still holds pretty well under these later studies. Walcott's radicle is hypothetic and Precambrian, and its most direct expression and outcome is his genus *Rustella* which, leaving no successors (in this table), stands out in independence as the fortified protegulum adult. Nearest to this in close collateral development stands *Paterina*, a durable genus reaching nearly through all Cambrian beds. From a distinct collateral descend the oboloids and in a near-by line, but distinct as far

as it has been tracked, the linguloids. These three lines constitute the main stocks of the *Atremata*.

The *Neotremata* with definite cardinal surfaces (such genera as *Acrotreta*, *Acrothele*, *Trematobolus*) indicate no marked convergence toward the *Atremata*. Mr. Walcott unites them close to the Precambrian radicle. This also he does with the *Protremata* (*Bilingsella*, *Syntrophia*, etc.). Indeed, one of the striking features of this table is its palpable absence of evidence of Cambrian convergence in the three great subclasses.

In 1892-94, when Hall and Clarke's "Introduction to the Study of the Genera of Paleozoic Brachiopoda" and "Introduction to the Study of the Brachiopoda" appeared, there were 28 recognized Cambrian genera. Dr. Walcott presents a total of 49 genera and subgenera of *Atremata* and *Neotremata* from the Cambrian. But it is to be noted that, notwithstanding its title, the work is not exclusively given over to the Cambrian faunas. The author has included a number of related genera and species, of all three subclasses, from the Ordovician, which help to make clearer the relations and range of these primitive expressions.

The scientific public knows that even with this vast contribution to our knowledge of the Cambrian fauna, Dr. Walcott's work is very far from complete. We have been let far enough into his accumulated Cambrian treasures to realize that his brachiopod book is but a foretaste, an intimation of the whole fauna under his eye. We can not restrain amazement at the tremendous expansion of ideas regarding the profusion and diversity of the Cambrian fauna which has followed the work of his hands. It is his own fault if we are led daily to expect the unexpected from this rich depository of life. In beauty and excellence of preservation the Cambrian beds of the Canadian Rockies, which he has especially upturned, surpass nearly all deposits of a later date, and with the light that they have cast upon familiar organisms long known to us from later beds, we have now to rehabilitate many familiar conceptions. In ultimate

significance the bearing of these investigations on the life conditions which preceded the Cambrian, is far-reaching, and must pave the way to a repair of our conceptions of it and gives us, too, a certain hope that unremitted diligence may bring to our distinguished protagonist of Precambrian life a sure and firm reward.

JOHN M. CLARKE

*Nutritional Physiology.* By PERCY G. STILES, Assistant Professor of Physiology in Simmons College; Instructor in Physiology and Personal Hygiene in the Massachusetts Institute of Technology, Boston. 12mo of 271 pages, illustrated. Philadelphia and London, W. B. Saunders Company. 1912. Cloth. \$1.25 net.

This little volume is a most welcome addition to the literature of nutrition. It is seldom that as much information of a reliable and useful kind is condensed in a publication of this size. The author well states that "the making of the book has been a study in elimination." He also states that it is intended to be used with other books and suggests the desirability of supplementary reading upon general biology, human anatomy, food chemistry and dietetics. We are informed that the keyword of the discussion is energy. The author has given us a careful and discriminating study of the best existing scientific evidence related to the physiological phases of human nutrition and he has treated his subject in language that is notably clear. His discussion is well organized and he has exercised a reasonable caution in his affirmations. Chemical formulæ and minute details have been excluded from the text and "used but sparingly in the notes," for "a certain preliminary knowledge of elementary science is assumed." The volume deals with processes rather than with chemical or physiological details. For instance, in discussing the unlikeness of the individual proteins on the basis of the "building stones" into which they may be separated, no detailed list is given of the protein cleavage products, but at the same time the general bearing of the knowledge we now have

in regard to protein cleavage and the nutritive relation of single food proteins upon the development of body proteins is clearly and fully presented. The origin of urea is discussed, but it is assumed that the student is familiar with the chemical reactions involved. In fact, we have presented to us the philosophy of nutrition minus minute chemical and physiological details. The evident intention is to give to the student a point of view and this purpose is accomplished with eminent success.

One of the characteristic features of this book is the type of illustrations used in order to make clear certain metabolic processes and nutritive relations. For instance, in dealing with the difference in the constructive value of the individual proteins, comparison is made to a house that is pulled down in order that another may be erected from its timbers. "If the second house is of an architecture entirely unlike that of the first, there will be many unavailable pieces to discard and the new building will be smaller than the old. It is not at all unlikely that the misfit fragments of building material will go into the cellar of the new house, later to be used as fuel. This is just what the body does." The structure of a molecule of food protein is also compared to type set up in a printed page. If this type is allowed to fall apart, it is a symbol of digestion and unless this is used to set up again exactly the same matter, there will be unused letters, just as in the human body protein building stones will be used for fuel purposes and not for construction unless the food proteins and the body proteins are alike in constitution. Familiar illustrations of this apt character are frequently used throughout the volume.

If any one portion of this volume is to be commended above another, it is the chapter upon the hygiene of nutrition. Though covering but twenty-three pages, this chapter has more value in its relation to practical dietetics than some whole volumes written by a less scholarly and discriminating author. In discussing nervous conditions as relating to digestion, some space is given to the treatment

of children as affecting the digestion of their food. It would be well if all parents could be made to heed the author's suggestions in regard to thoughtlessness in rebuking children at the table and the almost cruel practise of forcing them to eat what they dislike. The statements that "there is an element of hypocrisy in the attitude of parents who are selecting precisely what they please to eat while compelling little children to swallow food which repels" and "to oblige a child to finish a plateful of food against its inclination may be crass brutality" are forceful and should be heeded by those who have the care of the physical development of children.

The reader can but wish that the author had been more free in the use of cuts, for those which are given are very helpful.

W. H. JORDAN

NEW YORK AGRICULTURAL  
EXPERIMENT STATION

*Studies in Radioactivity.* By W. H. BRAGG, M.A., F.R.S. Macmillan. 1912. Pp. x + 196. \$1.60.

Physics owes to Professor Bragg two of the most important of its recent advances. He first conceived and successfully carried out experiments on the "range" of corpuscular radiations and on the "stopping power" of different substances for these radiations. These experiments, with those on scattering, which inevitably followed, have been chiefly responsible for such additions as have recently been made to our knowledge of the internal structure of the atom. The first 10 chapters—104 pages—of the book in hand are taken up with a presentation in clear, non-mathematical language, of the present status of our knowledge of "range," "stopping power," "scattering" and "ionization" as these terms apply to the  $\alpha$  and  $\beta$  particles. This material, culminating in C. T. R. Wilson's beautiful photographs of the tracks of  $\alpha$  and  $\beta$  particles, probably marks the end of the conception of the positive charge of the atom as a uniform sphere of positive electrification. It seems to demand instead some sort of a Saturnian atom.

Bragg's second important contribution has consisted in the amassing of evidence for the inter-convertibility of  $\beta$  rays and X rays, or  $\beta$  rays and  $\gamma$  rays. This evidence is presented in the second half (pp. 104–196) of his book, which deals wholly with studies on the nature of X and  $\gamma$  rays. That this evidence is exceedingly convincing admits of no dispute, but that it can be successfully interpreted in terms of a neutral pair theory is more than doubtful. Indeed so rapid have been the strides made during the past year in establishing the essential identity of X rays and light that I fancy that Professor Bragg himself would to-day interpret all his results in terms of an ether pulse theory instead of a neutral doublet theory, but it would have to be an ether pulse theory of the J. J. Thomson sort, in which the energy remains localized in space instead of being distributed uniformly over the wave front. For a clear statement of the apparent necessity for some sort of a localization of radiant energy in the wave front the second half of Professor Bragg's book could scarcely be excelled. One might wish that the author had brought out more emphatically the parallelism between the behavior of X rays and ultraviolet light, for it is in this parallelism that the chief argument against the neutral doublet theory is found.

The book is invaluable to every student of the absorbing problem of the nature of radiant electromagnetic energy.

UNIVERSITY OF CHICAGO

# BOTANICAL NOTES

## POLYSTICTUS VERSICOLOR AS A FOOD PLANT

In the course of some investigations made by Professor M. R. Gilmore in August, 1912, on the knowledge and use of the indigenous plants by the Dakota nation of Indians, the economic botany of the Dakotas, he learned of the use of *Polystictus versicolor* as a human food. The Dakota name is *Cha<sup>n</sup> na<sup>n</sup> pa<sup>1</sup>*.

<sup>1</sup> The raised n signifies a vanishing sound something like the French n.

which literally means "wood-ears" or "tree ears," the name, no doubt, being suggested by the shape of the fungus. It is used when young and tender and is prepared by boiling. Mr. Gilmore's informant was a man probably more than sixty years of age, speaking only the Dakota language, a man of more than average intelligence, a judge in the Indian court of the Wakpamni district of Pine Ridge Indian Reservation. He is of the Ogallala tribe of the Teton Dakotas.

#### AN EVERYDAY BOTANICAL MANUAL

THERE is evidently no good reason in these days for ignorance concerning the names and general classification of at least the higher plants, if we may judge from the attempts that are made by writers and publishers to supply popular manuals and handbooks. Some of those published in the past have not had much more to commend them than the wish on the part of the writer to help people who were more ignorant than he concerning the plants of some more or less vaguely defined area of North America. And yet the poorest of these had some value, and no doubt helped many people who could not have been induced to buy a better book. No doubt botanists have sometimes been unduly impatient with books of this description, while the non-botanical public has managed to get some of the information about plants which it craved, and which it could not find in the more accurate scientific publications.

But these merely tolerant words need not be used in regard to Dr. C. A. Darling's "Handbook of the Wild and Cultivated Flowering Plants," which made its appearance the latter part of 1912. The preface states that the object of the book is "to furnish a convenient and easy means of determining the wild and cultivated flowering plants found in the East." In carrying out this plan the author has used dichotomous keys of a kind so easily followed that with proper care one need not "run off the track" before finding the name of his plant, in its proper place in its family, order, subclass and class. A hint is given as to the proper pronunciation of the

scientific name when found, and an English name is provided for every species. A good glossary and (single) index closes this handy little book of 264 small octavo pages.

If this little book can find its way into the hands of the persons for whom it has been prepared it will serve a most useful purpose, and this part of the public may well feel indebted to the author who in addition to his duties as an instructor in botany in Columbia University has taken upon himself the very considerable labor of writing and publishing this little book.

#### THE EVOLUTION OF PLANTS

ONE of the most helpful books for the beginner in philosophical science is Professor D. H. Campbell's "Plant Life and Evolution," in Holt's American Nature Series, which appeared some months ago. It will be remembered that a dozen or so years ago the same author brought out a book entitled "Lectures on the Evolution of Plants," in which he emphasized the structural side of his topic. The book now under consideration, while considerably less technical, is really a supplement to the earlier work. That book arranged plant structures in evolutionary sequence; this one accounts for the structures, and their changes by a discussion of the factors concerned. The earlier book was structural, this one is philosophical. The first one appealed primarily to the botanist, while this one will appeal to a much wider circle of readers, in proof of which we may cite some of the chapter headings: *e. g.*, factors in evolution; the origin of land plants; environment and adaptation; the problem of plant distribution; the human factor in plant evolution; the origin of species, etc.

CHARLES E. BESSEY

THE UNIVERSITY OF NEBRASKA

#### SPECIAL ARTICLES

##### SUPPLEMENTARY NOTE ON THE SIGNIFICANCE OF VARIETY TESTS

SINCE the appearance in SCIENCE<sup>1</sup> of a note "On the Significance of Variety Tests," Dur-

<sup>1</sup>N. S., 36: 318-320, 1912.

ham<sup>2</sup> has arranged the data of the trials of peas made at Wisley in 1911<sup>3</sup> in a convenient form for statistical analysis.

Comparison with the wheat data already discussed is interesting. In wheat, selection has been *primarily* in the same direction—largeness of yield in bushels per acre—for all varieties. In peas, it has been in diverse directions. For the character here dealt with—time required for development—the tendency has been, consciously or unconsciously, to differentiate widely the varieties. Hence in the pea data, it is idle to lump all the materials together, for any constant thus obtained would be largely spurious and insignificant.<sup>4</sup> In practical tests one must decide between a series of closely similar strains—not between those which are widely and obviously differentiated; hence, we split the material up into the four classes recognized by Durham, that is, into 81-90, 91-100, 101-110, 111-120 day peas and calculate the inter-period correlation<sup>5</sup> for each class separately for the only economically important character<sup>6</sup> for which data are avail-

able—total days required for the formation of usable pods. Hence, designating by the subscripts 1, 2, 3, the three successive cultures of 1909<sup>7</sup> we have the following relationships:

For 91-100 day peas,  $n = 30$ ,

$$r_{12} = .16 \pm .12, r_{13} = .19 \pm .12, r_{23} = .12 \pm .12$$

For 101-110 day peas,  $n = 40$ ,

$$r_{12} = .43 \pm .09, r_{13} = .37 \pm .09, r_{23} = .78 \pm .04$$

For 111-120 day peas,  $n = 18$ ,

$$r_{12} = .27 \pm .15, r_{13} = .50 \pm .12, r_{23} = .45 \pm .13$$

All the values are positive. Their wide fluctuation and the magnitude of the probable errors is probably largely attributable to the necessary smallness of the number of varieties in each class.

It is clear that a single test when carried out in the manner of those of the Royal Horticultural Society has little decisive value concerning the merit of a variety. This is not intended as a criticism of these tests, for they are in comparison with many others apparently of a very high order of merit. But certainly they lend their emphasis to the point<sup>8</sup> made in the preceding paper.

Is it not time for a concerted and systematic effort on the part of those interested in agricultural science to put this important problem on a sound basis, biologically and statistically?

J. ARTHUR HARRIS

COLD SPRING HARBOR, N. Y.,

December 21, 1912

<sup>2</sup>Durham, F. R., "An Analysis of the Pea Trials at Wisley, 1911," *Journ. Roy. Hort. Soc.*, 38: 67-72, 1912.

<sup>3</sup>"Pea Trial at Wisley, 1911," *Journ. Roy. Hort. Soc.*, 37: 403-424, 1911. The two original papers must be consulted for the details that are here excluded for lack of space.

<sup>4</sup>As a matter of fact these constants have been calculated for another purpose, but they need not be published here.

<sup>5</sup>To be of value in determining the relative merit of varieties the performances of a given strain in a test should be a good basis for prediction as to the results of a subsequent experiment. To what extent this is true may be determined for any two or more series of trials of a number of varieties by determining the coefficient of correlation between their performances, correction being made when symmetrical tables are involved—i. e., when any determination is used both as a first and as a second member of a pair—for environmental heterogeneity from experiment to experiment. This does not apply to the pea data.

<sup>6</sup>The data for the individual growth periods give, on the basis of the total data, such irregular correlations that it is not worth while to consider them for the subclasses.

ON THE METAMORPHOSIS OF AN AMOEBA, VAHL-KAMPFIA SP., INTO FLAGELLATES AND VICE VERSA<sup>1</sup>

AN amoeba of the limax group isolated, in 1909, from tap-water in Oakland, California,

<sup>7</sup>Had the cultures been made at the same season in three succeeding years, the test would have furnished data of more value to the practical grower. Data for such tests are, as far as I am aware, not available.

<sup>8</sup>This has already been emphasized on general grounds by various students of agronomy. See especially C. V. Piper and W. H. Stevenson, "Standardization of Field Experimental Methods in Agronomy," *Proc. Amer. Soc. Agron.*, 2: 70-76, 1910.

<sup>1</sup>Presented to the Cincinnati Research Society, January 9, 1913.

was studied during the past year under varying conditions of environment. The culture contained the descendants of a single amoeba grown in symbiosis with a single species of bacillus.

My work was started with the idea of investigating the physical and chemical conditions necessary for the growth of this particular amoeba. When, in the course of the work, it was discovered that the trophozoites had the ability to turn, apparently at will, into actively motile flagellated forms, my efforts were directed mainly towards investigating, first, the effects of varying environment upon the morphology and development of the amoeba and, second, the conditions which led to the production of flagellated forms.

The trophozoites usually possess a single nucleus with the large karyosome and thick nuclear membrane characteristic of members of the limax group.

The flagellated forms vary in shape, but are most often egg-shaped or pyriform, with the nucleus situated at the pole, from which two long, delicate flagella arise.

These flagellates disappear instantly if a thin cover-glass is placed on a preparation, but may be watched for varying lengths of time in a hanging drop. The metamorphosis of one may be described briefly as follows: For a while it maintained the elongated form; then became pyriform, and whirled round and round, and in a minute or so, during its gyrations, it projected numerous waves of blunt pseudopodia; shortly it became elongated again. It progressed in this form until twenty minutes after the observation commenced, when it suddenly became motionless and spherical. In a few moments it projected a clear blunt pseudopod into which the endoplasm flowed and then it wandered off as a typical trophozoite of the limax type.

Throughout a long series of cultural experiments it was found that this metamorphosis occurred very inconstantly. Traces of various monovalent and bivalent salts seemed to exert no beneficial effect. Daily observations

on one subculture were made during more than two months without revealing any flagellated forms. However, it was finally discovered that if the trophozoites were first grown in hen's ovomucoid containing a trace of the egg yolk, the development of the flagellated forms was favored. Furthermore, that they could be constantly obtained if the cultivations were carried out in hanging drops placed in contact with an abundant supply of free oxygen.

The technique is as follows: a loopful from the surface of a yolk-ovomucoid culture containing the trophozoites is mixed with two or three loopfuls of distilled water on a cover-glass and placed on a Barber moist chamber at 22°-25° C. No flagellates may be seen in an hour or so, but hundreds may be seen after three or four hours.

Two "pure lines"—each originating from a single flagellate—were obtained for me by Dr. G. L. Kite, by means of the Barber isolation pipette. Both of these showed a much greater tendency to flagellate than the original stock.

Since the ability to turn over into a flagellated stage has been established as a generic character, a technique which will enable one to determine this power is evidently of importance.

In 1912 Chatton and Lalung-Bonnaire established the new genus *Vahlkampfia* (in honor of E. Vahlkampf, who was the first to make known the characteristic mitosis of these amoebæ) to include those members of the limax group which had the ability to flagellate. These amoebæ are said to be always uninucleated. Nuclear division is by promitosis. They multiply after nuclear division by simple fission. Their cysts are always uninucleate.

My findings show that these generic characters must be greatly extended. For example, under certain cultural conditions the trophozoites form endogenous buds; under other conditions, characterized by a reduced oxygen tension, the nucleus apparently divides repeatedly by amitosis, without division of

the cytoplasm, thus giving rise to large multinucleated forms containing as many as thirty or forty nuclei. When these multinucleated forms are placed in contact with an abundant supply of free oxygen the cytoplasm immediately begins to divide. Furthermore, the free oxygen supply starts off many of the multinucleated forms and their nuclei divide simultaneously.

These findings have raised the question, in my mind, as to the validity of the multinucleated genus *Pelomyxa* and the binucleated genus *Sappina*.

It may be of interest to describe here a reaction which I believe indicates the presence of peroxides in the living cell. When these amoebae are grown in ovomucoid containing a trace of sodium carbonate and then mounted in an aqueous solution of Grüber's methyl green, the granules within their cytoplasm exhibit a purple color in a few minutes. The nucleus does not give this reaction. Now methyl green is split by peroxides into a purple compound and this reaction occurs in the test tube only, in my experience, in the presence of traces of sodium carbonate.

If this reaction really indicates the presence of peroxides, it shows that the so-called "nutritional granules," or "plastids" in reality perform an important part in the oxidations of the cell, and would seem to add significance to the observation of Kite and Chambers, who found that the nucleus of the spermatogonia of the squash bug was composed of powerful reducing substances.

The complete details of this work will be sent to the *Archives für Protistenkunde*.

WM. B. WHERRY

CINCINNATI, OHIO

#### THE ILLINOIS STATE ACADEMY OF SCIENCE

THE fifth annual meeting of the Illinois State Academy of Science was held at Bradley Polytechnic Institute, Peoria, Illinois, on February 21 and 22, 1913, under the presidency of Professor Henry Crew, of Northwestern University. After the opening business was transacted, the president's address was given by Professor Crew upon

the title, "An Italian Academician." This address presented Galileo as an experimenter of the highest type—one who used the method of science in discovering some of the truths of nature at a time when the common practise was to deal with assertions about nature, or if the apparent facts of nature seemed to controvert assertions "to stare nature out of countenance." It is hoped that this excellent address will receive wide publication, for Professor Crew's special studies of the work of Galileo have resulted in the presentation of Galileo as a man of very much more far-reaching significance to modern science than most scientists have thought. Another special feature of the program was a symposium upon the "Science of Sanitation." The topics and speakers in this symposium were: "The Influence of Shallow Wells on Health," by Edward Bartow, director of the Illinois Water Survey, University of Illinois; "The Control of Stream Pollution," by Paul Hansen, Illinois Water Survey, University of Illinois; "Sanitary Aspect of Milk Supply," by P. G. Heinemann, department of bacteriology, University of Chicago; "Housing in Relation to Health," by Marion Talbot, department of household administration, University of Chicago; "Birth and Death Registration," by Frederick R. Green, American Medical Association, Chicago. This symposium proved unusually interesting to all the members who were present, and it is hoped by means of the annual volume of the academy's *Transactions* to give the symposium papers wide distribution throughout the state.

After an informal reception for members and friends of the academy, an excellent dinner was served by the department of domestic science of Bradley Polytechnic Institute; and in a period when efficiency in education is being demanded everywhere, it is a pleasure for the members of the academy to attest the efficiency of the service given by Bradley's domestic science department. The dinner and the service was entirely by students in the department, and no better dinner has been served to the academy. The after-dinner program consisted of a series of short addresses outlining the nature and significance of the past year's discoveries in each of several branches of science. This apparently impossible task was performed in such a way as to give the members a good perspective regarding the chief occurrences and the dominant points of view prevailing at present. The speakers were John M. Coulter, Henry B. Ward, Stephen A. Forbes, William S.

Bayley and E. W. Washburn. One of the purposes of the academy is to make science the property of the people, and no part of the program better met this purpose than these brief addresses which gave specialists in one science clear notions of the things being done in other sciences. The evening address was by Professor E. E. Barnard, Yerkes Observatory, University of Chicago, upon "Some Late Results in Astronomical Photography," and was illustrated with lantern slides made from the most recent and most valuable astronomical photographs. As the lecture ended doubtless a good many members felt as one said: "There is no mind-stretcher equal to astronomy."

The academy has had several committees at work during the past year, among which are the following: on conservation, on legislation, on calendar reform, on leaflets on high school science, on pure and applied science in high schools, on ecological survey. All of these committees are continued so that they may make further report next year, but the report of the ecological survey committee, S. A. Forbes, chairman, should be especially mentioned. The districts actively investigated and made the basis of special reports, printed or to be printed, are: the Chicago area; the Beach area of northeastern Illinois; the county of Jo Daviess in the northwestern part of the state and Fulton County in the central part of the state; the sand prairies of the state; the Charleston area with extensions over the eastern Illinois; and the Illinois River, with extensions to the Mississippi and the Ohio rivers. A statistical survey of the bird life of the entire state, made four years ago, showing numbers, distribution and ecological relations of the species is now being prepared for publication. The ecological relations of the crawfishes of Illinois are being investigated by a special student. The work upon the animal life of the Chicago area is soon to be published by the Geographic Society of Chicago. While this is not a part of the work of the academy, it has been done by one of its members, Dr. Shelford, and constitutes a part of the ecological work of the state. Dr. E. N. Transeau is publishing a report upon the algae of eastern Illinois, a report which notes 245 species, 23 of which have not previously been collected in North America, almost all these new forms having been found in old prairie ponds. Mr. T. L. Hankinson reports a most interesting and careful study of the distribution of the fishes of Coles County, a county drained partly by the Wabash system and partly by the Kaskaskia sys-

tem, thus offering peculiarly good opportunity for such a study.

The individual papers upon the program of the academy follow:

"A Celestial Sphere," an apparatus to be used in the study of descriptive astronomy, constructed and installed at the Chicago Academy of Science (illustrated), W. W. Atwood, Chicago Academy of Science.

"Chicago Academy of Science—An Educational Force in the Community" (illustrated), W. W. Atwood, Chicago Academy of Science.

"Annotated List of the Algæ of Eastern Illinois," presented in form of a summary, E. N. Transeau, Eastern State Normal School.

"The Sexton Creek Limestone in Illinois," T. E. Savage, University of Illinois.

"A Plea for the Organization of Local Natural History Societies," Ruth Marshall, Rockford College.

"A New Species of *Marionina* from Illinois," Frank Smith and Paul S. Welch, University of Illinois.

"A Black-crowned Night Heronry" (illustrated), Charles W. Finley, Western State Normal School.

"Reproduction by Layering in the Black Spruce," George D. Fuller, University of Chicago.

"Studies of Evaporation and Soil Moisture in the Prairie of Illinois," George D. Fuller and E. M. Harvey, University of Chicago.

"The Stratification of Humidity in the Forest," Wade McNutt, Highland Park High School, and J. R. Locke, Streator High School.

"The Distribution of the Fish in the Streams about Charleston, Illinois," T. L. Hankinson, Eastern State Normal School.

"The Disappearance of the Beaver," Elliot R. Downing, University of Chicago.

"The Stratigraphy of the Chester Group in Southern Illinois," Stuart Weller, University of Chicago.

"Cloud Studies" (illustrated), M. L. Fuller, United States Weather Bureau, Peoria.

The new officers for the following year are:

*President*—F. W. Dewolf, State Geological Survey, Urbana.

*Vice-president*—H. S. Pepoon, Lake View High School, Chicago.

*Treasurer*—J. C. Hessler, James Millikin University, Decatur.

*Secretary*—E. N. Transeau, State Normal School, Charleston.

The academy has a membership of over four hundred, forty-five new members having been elected at the recent meeting.

OTIS W. CALDWELL,  
Secretary

### SOCIETIES AND ACADEMIES

#### THE HELMINTHOLOGICAL SOCIETY OF WASHINGTON

The fourteenth regular meeting of the society was held at the residence of Dr. Stiles, February 6, 1913, Dr. Stiles acting as host and Dr. Cobb as chairman.

Dr. Stiles presented a note on "The Value of Protozoa in Determining Fecal Contamination of Foods." *Entameba coli*, *Lamblia duodenalis* and *Trichomonas intestinalis* are obligate intestinal parasites having an easily recognizable spore stage. Any given case of infection is *prima facie* evidence of fecal contamination of food, and of insanitary surroundings. The indicator value of these protozoa, a thing which has been overlooked heretofore, is greater than that of *Bacillus coli*. In some parts of the south, infection with these protozoa will range from 10 to 60 per cent. of the persons examined.

Dr. Stiles presented a note by Stiles and Boatwright on "Subjective Symptoms of Thymol." The paper notes the results of 464 administrations of thymol to 244 patients, each patient receiving 1 to 7 treatments. Of the 464 administrations, 55.8 per cent. had no untoward effect; 44.2 had effects of some sort; 14 per cent. had nausea due to thymol or to Epsom salts; 13 per cent. had weakness due to thymol, Epsom salts or the lack of breakfast; 9 per cent. had a burning sensation referred to "the stomach," due to thymol; 9 per cent. had dizziness; 3 per cent. had headache; 2.8 per cent. had attacks of vomiting; 1.7 per cent. had a burning sensation in the throat; 1 per cent. had pain in the stomach; 1 per cent. complained of sleepiness. There was one case of dyspnea due to idiosyncrasy to thymol, and one of fainting due to idiosyncrasy to Epsom salts.

Mr. Crawley presented the following note on "Initial Stages of *Sarcocystis* Infection."

According to Erdman, the spore of *Sarcocystis muris* germinates in the intestine of the host and liberates a toxin, sarcocystin, which causes the adjacent digestive epithelium to be thrown off. The spore sets free an amebula which penetrates the denuded area and attains the lymph spaces of the submucosa, where it establishes itself and remains for 28 to 30 days.

My own observations indicate that the above account is far from correct. Feeding experiments carried on during the past few years show that the spore, under the form in which it occurs in the cysts, bores its way into the cylinder cells of the epithelium, occurring in some cells two or three hours after feeding, and there comes to rest. The spore changes in shape, becoming broadly elliptical or round, concomitant internal changes resulting in the production at the periphery of a row of masses of chromatin closely resembling stages in the schizogony of a coccidian. This point may be attained twelve hours after feeding. At the end of twenty-four hours the parasites appear to have abandoned the intestine.

According to my observations, the epithelial denudation mentioned by Erdman follows instead of preceding the invasion of the cells, a phenomenon well known as a sequel of heavy infections by other protozoan parasites.

Dr. Cobb presented some figures and specimens of free-living nematodes. Some marine forms have structures suggesting similar structures in insects and birds. One of them has a proboscis which might function in much the same way as analogous organs which in birds or insects are used for extracting food from flowers.

Dr. Cobb suggested that the clumsy term *lateral organ* be dropped as a descriptive term, since there are many other nematode organs which are also lateral. Since we do not know the true nature of this structure, he suggested the substitution of the new term *amphid*, which is compact, descriptive and yet non-committal as to function. For somewhat similar reasons he suggested that the *ventral gland* be called the *rennette*. Nematodes possess many other ventral glands. He has previously published a note on the urea content of this structure, thus justifying the functional implication carried by the diminutive *rennette* (*ren*, kidney).

The secretary presented a note by Dr. Albert Hassall, on "Nomenclatural Oddities." Certain rules of the code of zoological nomenclature are not observed by some writers, and some practices not contrary to the code are nevertheless undesirable from many standpoints. Disregard of the code and of good usage makes considerable trouble for the bibliographer, cataloguer and indexer. Common offences are: The casual introduction of unnecessary synonyms or the deliberate substitution of new names for old on grounds that never had recognition in the code; the proposal of new

names in footnotes, indices, figure labels or other out-of-the-way places; the habit of labeling a name *new species* in two or more publications; and the naming of new species by flocks of workers, so to speak, some specific names being referable to a chain of as many as five authors who have collaborated in the description.

By unanimous vote the society instructed the secretary to prepare a letter protesting against the proposed changes in the international code of zoological nomenclature which are being advocated by the German Zoological Society, and to submit the protest to the Ninth International Zoological Congress.

MAURICE C. HALL,  
*Secretary*

#### THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

The 466th regular meeting of the Anthropological Society of Washington was held in room 43 of the new building of the National Museum at 4:30 P.M., February 18, 1913, the president, Mr. George R. Stetson, in the chair.

Professor W. H. Holmes read a paper on "Agricultural Implements of the Mound-builders," saying:

The rich alluvial and prairie country of the middle Mississippi Valley is especially adapted to the practise of primitive agriculture and here are found large numbers of skillfully made flint blades of large size suitable for hafting as hoes and showing unmistakable evidence of long usage in operations that gave the working end a high degree of polish. They are made of grayish flint or chert which occurs plentifully in the form of flattish nodules in southern Illinois. These nodules were readily shaped by fracture with stone hammers, and vast numbers were gotten out and worked up by the mound-building tribes. The processes of manufacture were demonstrated by the speaker and it was shown with what ease and rapidity the blades could be made.

It was also shown by examples obtained from the Missouri River tribes that hoes made of the scapulae of the buffalo were in use in very recent times and that the hoes found in excavating ancient sites near Omaha correspond with these recent Indian forms in shape, manner of hafting and surface polish, and that both display, although in bone, precisely the same kind of polish and markings as do the similarly shaped hoes of flint. It was suggested that these flint hoes were modeled after scapular hoes, since these were in

general use by the tribes and have doubtless been in use from very early times among all the tribes advanced to the sedentary agricultural status of culture.

Referring to questions of antiquity which have been raised recently in regard to the burials of the Omaha district, it was suggested that since the buffalo was a comparatively recent arrival in the Mississippi Valley, a culture in which the bones of buffalo are represented must be younger, not older, than that of the mound-builders, since no traces or pictorial representations of the buffalo are found within the older Indian mounds.

This paper was briefly discussed. Mr. Stetson read notes on certain implements lately found in Britain. Professor Holmes commented concisely thereon.

Professor Holmes then read a paper on "Scope and Relationships of History and Archeology."

The second paper embodied in outline a study of the nature and scope of archeology and of archeological research as related to the field of human history as a whole. The history of man, or anthropology, according to Powell's classification, may be considered under seven heads or departments, giving rise to as many branches of research, as follows: somatology, psychology, philology, sociology, sophiology, technology and esthetology. In working out its problems each of these seven branches employs every available agency of research within and without its particular field and makes use of every form of record in which the history of man is embodied.

The records or sources of information to be drawn upon in these researches are comprised under two principal heads: intentional or purposeful records, on the one hand, and non-intentional or fortuitous records, on the other.

The intentional records are of four forms, as follows: (1) pictorial or pietographic; (2) commemorative, taking the form of monuments; (3) mnemonic, in the form of tradition and lore, orally transmitted; (4) inscribed or written records. Fortuitous records take numerous forms: (1) the diversified material results of human activities in which the commemorative motive is absent, but which comprise the great body of the products of handicraft; (2) the immaterial results of human activity as embodied in language, beliefs, customs, music, philosophy, etc.; (3) the ever-existing unpremeditated body of memories which accrue to each generation and are in part transmitted adventitiously; (4) the record em-

bodied in the physical constitution of man which when properly read tells the story of his development from lower forms; (5) the record of intellectual growth and powers to be sought and studied in the constitution of the mind; (6) the environments which reveal the story of the nurture and building up of the race throughout the past.

It is from these diversified records of present and past times that the story of the seven grand divisions of the history of man must be drawn. Archeology stands quite apart from this classification of the science, traversing in its own way the entire field of research. It claims for its own more especially that which is old or ancient in this vast body of data. It is even called upon to pick up the lost strands of the earlier written records, as with the shadowy beginnings of glyphic and phonetic writing, and restore them to the historian. It must recover the secrets of the commemorative monuments, the tombs and temples intended to immortalize the now long-forgotten great. It must follow back the obscure trails of tradition and substantiate or discredit the lore of the fathers. It must interpret the pictorial records inscribed by the ancients on rock faces and cavern walls which men meant should last forever. All that archeology retrieves from this wide field is restored to human knowledge and added to the volume of written history.

The services of archeologic science are equally potent in the field of the fortuitous records of humanity, for it reads that which was never intended to be read. The products of human handicraft, present and past, which have recorded automatically the doings of the ages are made to tell the story of the struggles, the triumphs and the defeats of humanity. The fortuitous records embodied in the non-material products of man's activities of to-day, although in themselves not antiquities, are made to cast a strong light on the history and significance of the material things of the past. Even the body of knowledge gathered from many sources and stored in the memory of the living, though unreliable and transient as a record, may be made to illumine the past; and the physical and psychical characters of man are in themselves records and may be made to tell the story of their own becoming and to explain the activities and the products of activity throughout the ages. All that archeology gathers from this wide field of research is added to the volume of written history.

In the great work of assembling the lost pages and completing the volume of the history of man, archeology may well claim first place among the contributing sciences.

This paper was discussed by Messrs. Casanowicz, Carroll, Stetson, Babcock, Hewitt, Swanton and Neumann.

A SPECIAL meeting of the Anthropological Society of Washington was held March 6, 1913, at 4:30 P.M., in the auditorium of the new building of the National Museum, the president, Mr. George R. Stetson, in the chair.

Dr. Walter Hough read a paper on "Savage Mutilations for Decoration."

The paper was a short excursion into the enormous field of custom with regard to ethnic mutilations, and sufficient examples were given to lay the subject rather completely before the society. In it were described the most striking forms of head shaping by pressure in infancy; the various forms of teeth mutilations; ear, nose, cheek and lip modifications and ornaments; pressure and mutilations in the arms, waist and limbs, and modifications of the bones of the feet. With mutilations also should be considered, perhaps, extraordinary hair dressing and treatment of the finger nails.

Many slides were shown of tattooing, scarification and decoration of the skin by means of dyes and pigments, and some of their multifarious meanings given. On the whole, it was concluded that ethnic mutilations originated from many concepts, the more important being a desire for identification, in some cases individual, but in most cases tribal; a desire for ornamentation, mainly individual in its treatment, but following environmental and tribal fashions; and also very important mutilations growing out of superstitious and religious ideas.

Many ethnic mutilations also relate to sex, puberty, social rank, honor for warlike feats and the like. All these ideas, which at times have been advanced as the explanation of the causes, show that the matter is extremely complex. The bearing of ethnic mutilations on primitive surgery was also hinted at, as well as its effects on the development of costume.

Dr. Williams and Dr. Swanton made certain inquiries and brief appurtenant remarks, which Dr. Hough answered.

WM. H. BABCOCK,  
*Secretary*

# SCIENCE

NEW SERIES  
VOL. XXXVII. No. 953

FRIDAY, APRIL 4, 1913

SINGLE COPIES, 15 CTS.  
ANNUAL SUBSCRIPTION, \$5.00

## Books for Veterinarians

### *Buchanan's Veterinary Bacteriology* PRACTICAL

This is a comprehensive work on bacteriology as applied to veterinary science. Immunity, opsonic index, the manufacture of antitoxins, vaccines and tuberculin; the processes of reproduction and sterilization; antiseptics, biochemic tests, culture media, isolation of cultures, etc., are all presented. Yeasts and molds are also considered.

Octavo of 516 pages, with 214 illustrations. By ROBERT E. BUCHANAN, Ph.D., Professor of Bacteriology, Iowa State College of Agriculture and Mechanical Arts. Cloth, \$3.00 net.

### *Jordan's General Bacteriology* THIRD EDITION Adopted by U. S. Army

Professor Jordan presents fully the bacteriology of plants, milk and its products, dairying, agriculture, water, food preservatives; of leathertanning, vinegar making, tobacco curing; of household administration, and sanitary engineering.

Octavo of 623 pages, illustrated. By EDWIN O. JORDAN, Ph.D., Professor of Bacteriology, University of Chicago. Cloth, \$3.00 net.

### *Sisson's Veterinary Anatomy* SUPERB ILLUSTRATIONS

This superb work contains many hitherto unpublished data resulting from the detailed study of formalin-hardened subjects and frozen sections. It is an exhaustive gross anatomy of the horse, ox, pig, and dog, including splanchnology of the sheep.

Octavo of 826 pages, with 588 superb illustrations. By SEPTIMUS SISSON, B.S., V.S., Professor of Comparative Anatomy, Ohio State University. Cloth, \$7.00 net.

### *Lusk on Nutrition* SECOND EDITION TRANSLATED INTO GERMAN

The practical presentation of starvation, regulation of temperature, specific dynamic action of foodstuffs, influence of protein food, fat and carbohydrates and of mechanical work makes this book unusually valuable in the study of animal dietetics.

Octavo of 402 pages. By GRAHAM LUSK, Ph.D., Professor of Physiology, Cornell Medical School. Cloth, \$3.00 net.

### *Hill's Histology and Organography* SECOND EDITION

Dr. Hill covers the entire field of human histology, beginning with the preparation of material, the cell, the various tissues, on through the different organs and regions, ending with laboratory directions and fixing and staining solutions.

12mo of 468 pages, with 357 illustrations. By CHARLES HILL, M.D., formerly Northwestern University. Flexible leather, \$2.00 net.

### *Holland's Chemistry and Toxicology* THIRD EDITION

Dr. Holland's work embraces both inorganic and organic chemistry, with special attention to toxicology in every case where the substance under consideration has toxic properties.

Octavo of 655 pages, illustrated. By JAMES W. HOLLAND, M.D., Professor of Medical Chemistry and Toxicology, Jefferson Medical College. Cloth, \$3.00 net.

W. B. SAUNDERS COMPANY, West Washington Square, Philadelphia

## Natural History Material

ZOOLOGY

GEOLOGY

We have furnished all kinds of Natural History Material and apparatus to the leading Museums, Colleges and Schools of the world, for the past fifty years. We endeavor to have our material of the best grade obtainable, and our prices as low as the quality will permit. We invite comparison of materials and prices with those of all other dealers. To readers of Science we are pleased to send our catalogues and price lists free.

### Recent Catalogues

College Ave.

Rochester, N. Y.

## UNION OF SOUTH AFRICA

Department of Agriculture

### Appointment of Assistant Entomologist

Applications are invited for the post of ASSISTANT ENTOMOLOGIST in the Department of Agriculture of the Union of South Africa.

Applicants for the post must have had a College education embracing entomology and allied natural science courses, and must be capable of undertaking investigations of insect problems. Practical experience in economic entomology will be a recommendation.

The salary attaching to the post commences at £350 per annum and rises, subject to satisfactory service, by annual increments of £20 to a maximum of £450, but in the case of a fully competent man the prospects of promotion to a higher grade are good. In certain districts a local allowance is payable in accordance with the Regulations of the Public Service.

The successful candidate will be required to serve on probation for a period of twelve months and will be expected to acquire a knowledge of the Dutch and English languages within a reasonable period.

Applications supported by certificates of birth, health, character, education, previous employment or professional qualifications, and languages will be received by the undersigned not later than April 30, 1913.

P. J. H. HOFMEYER,

Secretary Public Service Commission.

Office of the Public Service Commission,  
P. O. Box 545, Pretoria, S. A.

### ELEVENTH EDITION

## THE MICROSCOPE,

an introduction to Microscopic Methods and to Histology, by SIMON HENRY GAGE of Cornell University. The 11th edition has eight pages of new matter and corrections, otherwise it is like the 10th ed. Price \$2.60 postpaid.

COMSTOCK PUBLISHING CO., Ithaca, N. Y.

# Science and Education

*The Anthropological Society of Washington:* W. H. BABCOCK . 537

IN the investigation of natural problems the most conspicuous or bulkiest character does not always furnish the most convincing evidence. We readily see the mass of diatomaceous earth, but we do not understand its gritty quality, nor can we appreciate its origin until we have studied the minute, individually almost negligible frustules which make it up; sandstones or limestones may form great cliffs, but it requires the comparatively insignificant fossil to finally reveal the origin and the place of the rock. Similarly, in the study of the Pleistocene we encounter gross features which have their value—we find variously comminuted and diversely arranged materials in great bulk; we find topographic and physiographic characters on a large scale; yet the best evidence which we have concerning the conditions under which certain parts of the Pleistocene formations were deposited is furnished by the fossils which usually form a small and not always conspicuous part of the deposits.

Both plant and animal fossils have been found in the various subdivisions of the Pleistocene. The former consist chiefly of the leaves and wood of gymnospermous and angiospermous trees and shrubs, mosses and diatoms; the latter of some insects, a conspicuous, though limited, mammalian fauna, and the mollusks which form the most widely distributed and most universally present group of all.

<sup>1</sup> Address of the vice-president and chairman of Section E—Geology and Geography—American Association for the Advancement of Science, Cleveland, 1912.

The plant remains and insects are too few and too widely scattered to form a satisfactory measure of conditions; the mammalian fauna is but little better in this respect and, moreover, consists of species which are for the most part extinct, and whose exact habits are not known; but the mollusks are not only most widely distributed in the Pleistocene deposits, but belong practically without exception to species now living whose habits may be very accurately determined. For these reasons the mollusks form the most important and most significant group of Pleistocene fossils.

Aside from the marine species of the coastal formations, which will not be here considered, the Pleistocene and modern species of mollusks naturally group into three rather well-defined divisions according to habits:

1. *Fluviatile species*, inhabiting perennial streams and lakes. These are chiefly bivalves, especially larger *Unionidae*, and operculate gill-bearing gastropods. A few aquatic pulmonates, like *Lymnaea emarginata* and *Planorbis truncatus*, also prefer larger bodies of water.

2. *Pond species*, inhabiting ponds, bogs and borders of smaller streams, which are likely to become dry during a part of the summer, and also the shallow swampy borders of larger bodies of water. These species are chiefly aquatic pulmonates, with a few smaller bivalves, especially of the genus *Pisidium*.

3. *Terrestrial species*, living among plants, sometimes on the bark of trees, often under leaves, sticks and stones. Among them are two operculate prosobranchs, closely related to aquatic species of the first group, but the great majority are terrestrial pulmonates. A few species, such as *Succinea retusa*, *Zonitoides nitidus*, *Vertigo ovata* and *Carychium exiguum*,

naturally group with the terrestrial pulmonates, but they are commonly found in wet places, and sometimes live in the water for a time, behaving then like the aquatic pulmonates of the pond group.

The members of the pond and terrestrial groups are closely associated with plants which they require for shelter and in most cases for food. The terrestrial forms are most abundant on forested areas, but certain species, such as *Succinea grosvenorii*, *Cochlicopa lubrica*, *Vallonia gracilicosta*, etc., also extend into more open territory.

While all the terrestrial species require some moisture for activity, the amount which may be found at times under a leaf or stick, or among plants on a dewy morning, or after a rain, is entirely sufficient for the purpose. This supply of moisture is irregularly intermittent, and the mollusks remain inactive while waiting for a return of favorable conditions. Sometimes they protect themselves by a mucous epiphragm, or they creep under leaves or sticks, or burrow into the soil. Long-protracted dry seasons are fatal to many of them.

The fossil mollusks are distributed through a variety of formations. Those of the Aftonian, the Don beds, the Florencia formation and similar older Pleistocene deposits, like those of the more modern alluvial beds, present the fluviatile and pond facies in the main, though there is often a strong admixture of terrestrial forms. Those of the loesses are terrestrial in the main, with comparatively rare additions of pond types and a total absence of fluviatile forms.

Practically all of the species found in the various Pleistocene formations are living upon the continent to-day. Such exceptions as *Oreohelix ioensis* from the loess and species of *Pisidium* and *Lymnaea* recently described from indefinite alluvium,

do not materially affect the truth of this statement, for these may be mere races, or a more critical study of these difficult genera may show that the apparently extinct forms are living to-day. They are certainly very closely related to existing forms, and suggest no peculiar set of conditions.

Because of the practical identity of the fossil and certain modern molluscan faunas important conclusions may be drawn concerning the conditions which existed at the time of the deposition of the fossiliferous deposits.

The first question which naturally comes to the mind of the student of Pleistocene geology in this connection is this: Could these mollusks have lived under glacial or near-glacial conditions? As in so many other cases, the measure of the past must here be sought in the present. Unfortunately, we do not anywhere have conditions which exactly parallel those which existed in the interior of our continent during the several advances of the ice-sheets. The climate of Alaska is so materially affected by warm ocean currents that no fair basis for comparison can here be established. The Antarctic region presents no partly glaciated continents, and comparisons are here impossible. Perhaps Greenland offers the nearest parallel, but even here in the study of plant and animal life we have to deal with a narrow coastal strip the climate of which is manifestly affected by the proximity of the sea.

From this narrow strip Möller reported, in 1842, four species of terrestrial mollusks (a *Vitrea*, a *Pupa*, a *Vitrina* and a *Succinea*) and three species of pond snails, two of the genus *Lymnæa* and one of *Planorbis*. These species were all represented by few widely scattered individuals, and constitute a very scant fauna. Nowhere in all the barren ground belt border-

ing the Arctic ice have such combinations of species been observed as we find in the various Pleistocene deposits of our country. The latter suggest rather a region very similar to the present northern part of our country, in the main, with relationship in some of the deposits with the fauna of the southern states, and in others some affinity with that of the coniferous belt to the north.

Our present knowledge of the habits and distribution of the fossil and modern mollusks forces the conclusion that the deposits containing these species are interglacial or post-glacial, and that they were formed during a period of mild climate.

The second important question concerns the immediate conditions under which the various deposits were formed. To answer this question intelligently on the basis of the molluscan fauna we must understand the habits of the mollusks as well as the conditions under which the land and freshwater forms may mingle.

For purposes of comparison your essayist has made extensive studies of the habits of the modern molluscan fauna of the Mississippi Valley, and has compared large series of shells thrown up along the shores of larger streams and their smaller tributaries, as well as ponds and lakes, with the shells obtained from various Pleistocene deposits and from more modern alluvium, and nowhere has he found any evidence that the conditions under which the Pleistocene deposits were formed were materially different from those which are in operation in the same region to-day.

All of the Pleistocene deposits, with the exception of the loesses and certain buried sand dunes, are aquatic, and a comparison of their molluscan contents shows the same peculiarities and the same variations as are presented by the modern alluvial and water-drifted fauna.

Some of these points of similarity are brought out by a comparison of the mollusks from various deposits. Thus the Aftonian beds of Harrison and Monona counties, Iowa, have yielded 28 aquatic species and 9 terrestrial species;<sup>2</sup> the Don beds, 42 species, of which all but two are aquatic;<sup>3</sup> the Florencia formation, 30 aquatic and swamp species and 19 terrestrial species;<sup>4</sup> the buried silt in the Illinois Central cut in Sioux Falls, 14 aquatic and 2 terrestrial species, one of the latter doubtfully belonging to the deposit;<sup>5</sup> the more modern river alluvium of Harrison County yielded 18 aquatic and swamp species and 19 terrestrial species;<sup>6</sup> the lacustrine alluvium of West Lake Okoboji exposed by recent canal excavations, yielded 27 aquatic and swamp species, and 1 terrestrial species; modern drift along the Big Sioux River opposite Canton, South Dakota, contained 18 aquatic and 5 terrestrial species; similar drifted material along the Missouri River at Rulo, Nebraska, showed 12 pond and swamp species, and 15 terrestrial species; and drifted material on the north shore of Miller's Bay, West Lake Okoboji, Iowa, contained 14 aquatic and marsh species and 14 terrestrial species.

These lists indicate that terrestrial mollusks are not uncommon in the various alluvial deposits. It should be remembered, however, that as a rule the terrestrial species are represented by very few individuals which accidentally drifted in from adjacent land surfaces, while the aquatic species belonging to the genera

*Sphaerium*, *Pisidium*, *Campeloma*, *Valvata*, *Amnicola*, the larger species of *Lymnaea*, *Physa*, *Planorbis*, *Segmentina* and *Anacylus* occur in larger numbers.

In those cases in which larger numbers of terrestrial forms occur, as in the Miller's Bay and Rulo lists, they may be traced to nearby wooded bluffs, and it is evident that the relatively large number of terrestrial forms in the Harrison County alluvium and the Florencia formation may be traced to the same source.

It is evident that the shells do not drift far in any case. The Missouri River contains few aquatic mollusks, but its smaller tributaries usually show an abundance of them. Yet rarely are fluviatile shells found in modern river drift along the Missouri, and the aquatic species are of the pond type prevailing in small ponds along the main river, as is shown in the Rulo list. Shells of terrestrial species which are limited in their distribution are also seldom found at any distance from their habitat. This is strikingly illustrated by *Helicina occulta*, which is now restricted to limited and widely separated areas. Thus at Iowa City a colony inhabits a half-acre of wooded bluff, and in thirty years your essayist has found but one fresh shell along the creek at the foot of the slope, and none along the nearby river to which the creek is tributary.

A recently discovered colony of this species in a similar situation along the Cedar River above Cedar Rapids, Iowa,<sup>7</sup> gives like results. Various students of mollusks have collected in this region, yet no fresh shells of this species were ever observed in the drifted material along the Cedar River. The Miller's Bay list shows that 14 species of terrestrial shells were carried across the bay from the wooded southern shore, yet repeated dredging in the bay has brought

<sup>7</sup> By Mr. E. G. Grissel, of Cedar Rapids, Iowa.

to light only four of these species, represented by very few individuals, which had dropped to the bottom of the bay. Terrestrial shells which drift into water are soon cast ashore.

Nearby wooded slopes frequently contribute terrestrial shells to ponds and streams, but the latter invariably supply a relatively large number of shells of aquatic species.

It is also noticeable that such species as *Zonitoides nitidus* and *Succinea retusa*, of low grounds, and *Helicodiscus parallelus*, *Vitrea hammonis*, *Bifidaria armifera*, *B. contracta*, *B. pentodon*, *Zonitoides arbores* and *Z. minusculus*, which are common on timbered alluvial flats and which occur so frequently in alluvium and modern river drift, are relatively very rare in terrestrial deposits like the loesses.

Another method by which terrestrial shells sometimes find their way into alluvial deposits has been observed where shallow ponds become dry during the summer. These ponds usually contain aquatic pulmonates, and their shells remain in the alluvium of the pond. Terrestrial species then creep out over the exposed surfaces, not infrequently leaving their shells to mingle with those of the pond species. The subsequent flooding of the pond results in the inclusion of both types in the alluvium of the pond. In the alluvium of one pond of this type between the Lakes Okoboji, Iowa, 12 aquatic and 5 terrestrial species were found, the latter being represented by few individuals.

Still another method by which aquatic species may be buried at altitudes higher than the level of the free water surface may be observed in seepy places fed by permanent springs. Such spots are not uncommon even on higher slopes and they frequently contain aquatic species belonging to the genera *Pisidium*, *Lymnaea* and

*Physa*, probably introduced by small wading birds. Terrestrial species from nearby surfaces may creep out or be carried into the bog and the shells of both will then be mingled in the deposit of the bog. In one of these small bogs near Council Bluffs, Iowa, located at an altitude fully twenty feet above the high-water level of the Missouri River and closely surrounded by a forest, 5 terrestrial and 1 aquatic (*Pisidium*) species were collected, while in another on a prairie slope near West Lake Okoboji 3 aquatic species belonging to the genera *Pisidium*, *Lymnaea* and *Physa* were collected at an altitude of more than forty feet above the lake. In the latter case the surrounding prairie surfaces contributed no terrestrial species.

And finally individual specimens of aquatic species of mollusks may be carried to uplands by aquatic birds and insects, where their shells may ultimately be included in terrestrial deposits.

In order that the value of these molluscan faunas may be properly measured it is necessary that they be taken collectively. A single terrestrial shell does not make a land deposit, neither does a single aquatic shell make a water deposit. In water deposits aquatic shells always form a conspicuous part of the fauna, even though locally they may not predominate. In subaerial deposits aquatic shells may occur, but they are rare and local, and the dominant types are terrestrial. Strictly terrestrial Pleistocene deposits are of two types: buried sand dunes and the loesses. Buried sand dunes are not uncommon in the upper Mississippi Valley, excellent illustrations being found near Gladstone, Illinois; north of Iowa City, Iowa; at Hooper and West Point, Nebraska, and at other points. Neither buried nor surface dunes contain shells so far as observed.

The loesses are much more satisfactory

for our purposes, because they frequently contain fossils and offer by far the best opportunity for the study of Pleistocene terrestrial mollusks. In these deposits terrestrial forms vastly predominate, and fluviatile forms are wholly wanting. So much has been written on this feature of the subject that only reiteration is here possible.

Fresh-water shells in the loess are very few. They belong to species which inhabit small ponds and boggy places. They are not of the types found in streams and lakes. They are local in distribution, and in a number of cases clearly associated with buried ponds. Ponds are not rare in high places in loess regions. They frequently contain the smaller *Lymnaea*, etc., which are sometimes found in the loess, aquatic birds and insects probably being responsible for their introduction. Such ponds, if buried by subsequent depositions of loess, would present exactly the conditions under which aquatic shells are usually found in the loess. The vastly predominating forms are terrestrial—*upland terrestrial at that*. Some have become extinct in the loess region, but occur westward and southwestward in the drier part of the continent. Such are *Pupa muscorum*, *P. blandi*, *Sphyradium edentulum* var. *alticola*, *Pyramidula shimekii* and *Oreohelix iowensis*. Others like *Succinea grosvenorii* and *Vallonia gracillicorta* are still found in the loess region, but they prefer dry, often open grounds. The land species which prefer wet grounds are conspicuously absent from the loess.

The usual type of the fauna of the northerly loess is well illustrated by the fossil and modern fauna of King Hill, South St. Joseph, Missouri. This elevation rises 225 feet above the Missouri River bottoms and is capped by a thick bed of yellow loess which is quite fossiliferous to the very sum-

mit. The northeastern slope is covered more or less with low shrubs and stunted trees from twenty to eighty feet below the summit, merging below into a native grove. The loess at the summit yielded nineteen terrestrial species. Of these seven were also found living on the shrub-covered northeast surface in a relatively very dry habitat. With the latter were associated six additional terrestrial species which were not found in the summit loess, but all of which are known from the loess of the Missouri Valley. The nineteen fossil and thirteen modern species are all strictly terrestrial and the six species which are common to both well characterize the habitat of the entire fauna. A more careful examination of both the loess and modern surface faunas near the summit of King Hill would no doubt reveal a larger number of species common to both.

The fossil mollusks do not enable us to determine the age of any of the Pleistocene formations. The fossils of the Aftonian are not sufficiently distinct from those of modern alluvium to permit the drawing any conclusion other than that the conditions of deposition were much the same. They do not enable us to distinguish between the loesses, for the fossils of the gray and the yellow loesses are, in larger series, essentially the same. But they give us an excellent measure of the conditions which prevailed at the time of the deposition of the various fossil-bearing Pleistocene strata.

The fact that several ice sheets advanced into the upper Mississippi Valley has been well established. The advance and retreat of these several ice sheets were in all probability very slow, resulting in a gradual transition to and from a glacial climate. This suggested the desirability of search for evidence of such gradual transition among the mollusks of the several interglacial periods. But no such evidence has

as yet been found, and it is evident that the fossiliferous Pleistocene deposits were formed after the interglacial and postglacial conditions had been fully established.

In no known Pleistocene deposit is there a vertical gradation of species which can be accounted for on climatic grounds.

The variation in horizontal distribution does not in any case indicate a climate of greater severity than that which exists in the same region to-day. The determinable deposits containing fluviatile and other aquatic shells are of such limited extent north and south, and, moreover, the species which they contain are now so widely distributed that they present no evidence of climatic variation.

The terrestrial mollusks which are found in the Pleistocene deposits are also now of very wide distribution and the variation which they exhibit in species, form and size is not at all determined by latitude, but rather by the edaphic conditions under which the forms existed. In both cases the species are those of modern faunas whose habits are well known.

Variations in the Pleistocene fauna are nowhere better illustrated than in the loess, which has a wide distribution both north and south, and east and west, in the Mississippi Valley. If we begin in the northwestern part of the loess area in Nebraska and western Iowa, we find that the dominant species in the loess are *Pupa muscorum*, *P. blandi*, *Pyramidula shimaki*, *Succinea grosvenorii*, *Oreohelix ioensis*, *Vallonia gracilicosta*, *Bifidaria procera*, *Sphyradium edentulum alticola*. These species all belong to a fauna characteristic of the dry western regions, *Pupa muscorum* alone passing by a wide detour northward to the northeastern part of the country. Other species belonging to more easterly faunas appear, as a rule, in smaller numbers. Southward along the Missouri

River, as in northwestern Missouri, larger forms, such as *Circinaria concava*, *Pyramidula alternata* and *Polygyra multilineata*, more characteristic of eastern and southeastern faunas, begin to appear in larger numbers. The change southward along the Mississippi is even more striking. In the northerly deposits along the Mississippi *Helicina occulta*, *Pyramidula striatella*, *Succinea ovalis* and *S. avara* are among the most common species. *Pupa decora* is also abundant in both northern and northwestern loess, and while it is largely a boreal species, like *Pupa muscorum*, it extends along the western mountains well into our dry western region.

Southward along the Mississippi the loess molluscan fauna changes in essentially the same manner as the modern fauna of the surface. At Hickman, Kentucky, the larger helices (so prominent in the southeastern modern fauna) already appear in large numbers and *Pyramidula solitaria*, carinate *Pyramidula alternata*, *Polygyra tridentata*, very large *P. albolabris*, large *P. profunda*, a few *P. elevata*, *P. fraterna*, *P. fraudulenta*, *P. appressa*, *Omphalina fuliginosa*, large *Circinaria concava*, more abundant *Pyramidula perspectiva* and *Gastrodonta ligera*. These species already form the most conspicuous feature of the loess fauna. *Helicina occulta* still appears, though here approaching its southern limit. Still farther south at Dyersburg, Tennessee, a similar fauna appears in the loess, but *Helicina occulta* is not common, reaching here its southern limit and *Pyramidula striatella*, so common in the north, also becomes rare. Still farther south on the west side of the Mississippi River at Helena, Arkansas, the loess fauna becomes still more characteristically southern, and in addition to the larger helices already mentioned the large

form of *Succinia ovalis*, *Omphalina kopnodes*, *Vitrea placentula* and *Helicina orbiculata* appear in conspicuous numbers. The last three species are distinctively southern. *Helicina occulta* has wholly disappeared and its place has been taken by *Helicina orbiculata*. The richly fossiliferous loess of Natchez and Vicksburg, Mississippi, also contains the forms common at Hickman and Helena, and the presence of *Polygyra obstricta*, *P. inflecta* and *P. stenotrema* still further stamps the fauna as distinctively southern.

But in this variation in the wide loess region there is nothing which suggests a transition or change from cold climate to warm climate faunas or *vice versa*. The variation, as we find it in the loess is practically exactly duplicated in the modern fauna of the surface. The only conclusion, then, which can be drawn from the fossils of the loess is, that during the deposition of the several loesses climatic conditions were not materially different from those which exist in the various parts of the same general region to-day. Such differences as do exist point rather to a drier climate in the northern part of the loess-covered area than that of to-day.

Emphasis has sometimes been placed upon the depauperation in size of certain loess shells, as evidence that the climate in which they existed was colder than that of to-day. These depauperate shells are found only in the northern part of the loess area, in Iowa, Nebraska, etc. Their exact counterparts are found living to-day in the drier portions of the same region. And corresponding differences do not occur in more easterly series which represent differences in latitude. It is evident that the depauperation is due to drouth and not to a low temperature, and the abundance of these depauperate shells in the northern loess reinforces the evidence already noted

that the climate of this region was then somewhat drier than at present.

The earlier hasty conclusion in this case illustrates only one of the difficulties which the student of geology who has not given special attention to the mollusks encounters in his efforts to determine the conditions under which various Pleistocene deposits were formed.

Another results from erroneous identifications of deposits. An illustration of this is furnished by the Otis Mill section in South Dakota opposite Chatsworth, Iowa, which has been referred to the loess. The section, in fact, consists of Aftonian silt and sand, Kansan drift and true loess. The fossils, to which reference is usually made in connection with this section are of the usual alluvial type and belong to the Aftonian part of the section only, none being found in the capping loess. Still other errors result from erroneous identifications of species. Thus *Carychium exile*, the species usually found on high ground, has been identified as *C. exiguum*, a species which is frequently amphibious. Other errors arise from the assumption that species of the same genus have the same habits, and that their presence in various deposits indicates like conditions. This is often far from true, thus, *Zonitoides arbores* and *Z. nitidus* are similar in appearance, and closely related, yet the former is an upland species, while the latter is found in low grounds and is sometimes amphibious. Similarly, *Succinia avara* is upland, while *S. retusa* is amphibious; *Pomatiopsis lapidaria* is terrestrial, while *P. cincinnatiensis* is found only in somewhat deeper water in large ponds and lakes; *Planorbis trivolvis* lives in shallow waters in ponds and swampy borders, while the similar *P. truncatus* is found only in the larger lakes in deeper waters. *Lymnæa palustris* and *L. emarginata* show a similar difference in

habit, the latter being a deep water form; *Physa gyrina* is a species common in small ponds, while *P. integra* prefers river borders and *P. sayi* inhabits larger ponds and lakes; and similar variations in habit may be found in the species of various genera such as *Bifidaria* and *Vertigo* among terrestrial genera, and *Amnicola* and *Pisidium* among aquatic genera.

It is, therefore, not safe to jump at conclusions on the basis of mere relationship. A student of geology who would correctly measure the conditions which prevailed during the time of deposition of the various fossiliferous Pleistocene formations must not only accurately identify the fossil species, but he must learn to know the habits of the modern representatives of the same species.<sup>8</sup>

THE STATE UNIVERSITY OF IOWA

#### RAMSAY HEATLEY TRAQUAIR

ICHTHYOLOGISTS all over the world have read with profound regret of the death of Dr. Ramsay Heatley Traquair, the eminent authority on fossil fishes. Dr. Traquair had long been regarded as the dean of paleichthyology, and had been revered by those in his field, both for his personality and his scientific achievements, as few men ever were. It was a shock to them to realize that he was no more among them. His work in ichthyology was of a fundamental kind, like that of Huxley or of Johannes Müller in zoology, and much of it has long since become incorporated among the established principles of the science. Indeed, Dr. Traquair may be regarded as the founder of modern paleichthyology, and his name, we believe, will stand next to that of Louis Agassiz, as the most illustrious in the history of this science.

<sup>8</sup> A supplementary table of mollusks, containing twelve lists of fossils and six lists of shells obtained from modern drift along streams and lakes, has been published by the author, and will be sent on application to members who are specially interested.

Ramsay Heatley Traquair was born at Rhynd, Perthshire, July 30, 1840. He was the youngest son of a Scottish minister. As a boy, he was sent to a preparatory school in Edinburgh, where his quiet bearing and studiousness attracted the attention of his teachers. Almost from childhood he manifested a deep love of nature, and as a boy he frequented a small natural-history shop kept by an old woman in Edinburgh, where were displayed minerals, fossils and shellfish; these no doubt stimulated his imagination and helped to nurture a growing love of natural history. As he grew older, he would go on excursions into the hills around Edinburgh in quest of paleichthyological specimens. On one of these trips, the story runs, he found a nodule with a portion of a palæoniscid fish, and was greatly surprised to learn that no book then available gave an adequate account of it. It was his ardent love of natural history that led to his choice of medicine as a profession, for this was the only science, at that time, that afforded both a foundation for natural history studies and the means of a livelihood. He entered the University of Edinburgh as a student of medicine in his seventeenth year, and he seems to have been a good student. His holidays were spent in collecting and studying fossils. As the end of his studies approached, it became more and more plain to him that he ought not to practise his profession but seek an opening in science. He took his degree in 1862, receiving a gold medal for his thesis on the asymmetry of flatfishes. In this year, too, he published his first paper, "On the Occurrence of Trilobites in the Carboniferous Limestone of Fifeshire."

For several years after graduation he held minor posts in the school of medicine, first as prosector and later as demonstrator of anatomy. This period afforded him an opportunity of acquiring skill in making anatomical preparations, besides allowing him to be near his favorite fossil hunting grounds. During 1866-67, he held the professorship of natural history in the Agricultural College at Cirencester, where he taught botany and devoted his spare time to the study of local geology

and fossil fishes. His well-known memoir on *Pygopterus* belongs to this period, having been published in 1867.

During the next six years he held the chair of zoology in the newly established College of Science in Dublin. This post was more congenial than his previous ones, but it is plain, from the few papers published during these years, that he lacked materials for carrying on his studies in paleichthyology. His opportunity, however, came in full measure in 1873, when he was appointed keeper of natural history in the Museum of Science and Art (now the Royal Scottish Museum), at Edinburgh. Shortly before leaving Dublin he married Miss Phoebe Anna Moss, whose work as a painter was just beginning to attract attention;<sup>1</sup> she is the daughter of the late Dr. William Moss, of Dublin.

Dr. Traquair held the post of keeper for thirty-three years, retiring in 1906 at the age of sixty-six. His most brilliant and most lasting work was done during this time. He had at his disposal a magnificent collection of paleozoic fishes, including the materials brought together by Hugh Miller and used by him in his preparation of "Old Red Sandstone" and other works. Moreover, within easy reach of Edinburgh were a number of localities where fossil fishes could be easily procured. But it should not be thought that Dr. Traquair devoted all his time, during these years, to his studies: he gave much attention to building up the zoological collections at the museum. The synoptic exhibit in this subject, which is displayed in a large square gallery, is one of the completest, and perhaps the best of its kind, in the world. It is the admiration of all zoologists who visit the museum.

<sup>1</sup> Mrs. Traquair is widely known for her mural decorations. Her principal work is the series of mural paintings in the Catholic Apostolic Church in Edinburgh, which took four years to complete and is mentioned as one of the sights of Edinburgh. She has also done exquisite work in book illumination, decorative bookbinding and in enameling. For an appreciation of Mrs. Traquair's work, see A. F. Morris, "A Versatile Art Worker," *The International Studio*, XXV., 1905, pp. 339-343.

A few years after Dr. Traquair's retirement his health began to fail and during the past year or two it was felt by his friends that the end could not be far off. He died in his seventy-third year, on November 22, 1912, in his beautiful home, at the foot of the Pentland hills, at Colinton, near Edinburgh.

Many honors came to Dr. Traquair in his lifetime. He was an honorary or corresponding member of many learned societies throughout the world, including the New York Academy of Sciences, to which he was elected in 1899. He became a member of the Royal Society of London in 1881; in 1893 his alma mater conferred on him an honorary LL.D. He received a number of medals in recognition of his services to science—the Neill medal of the Royal Society of Edinburgh in 1878, and the Makkougall-Brisbane in 1901; the Lyell medal of the Geological Society of London (1902), and a Royal medal of the Royal Society in 1907.

Dr. Traquair's studies were embodied in about 130 memoirs.<sup>2</sup> He was not a voluminous writer, as natural history writers go these days, but whatever came from his pen was so carefully, so conscientiously elaborated, that even his smaller papers were highly valued by those in his field. Fossil fishes are often very imperfectly preserved, and authors are occasionally carried away into seeing anatomical details where none really exist. But Dr. Traquair never let his imagination have sway where his specimens were imperfect. His accuracy was almost proverbial. Considering the vast amount of detail contained in his papers, it is remarkable how little of it has ever been debated. Indeed, Dr. Traquair has been considered by some even over careful, so that his results were sometimes held back for a long time before publication. Thus, Dr. A. S. Woodward has lately pointed out that Dr.

<sup>2</sup> A bibliography of Dr. Traquair's scientific writings appeared in the *Geol. Mag.*, dec. v, Vol. VI., 1909, pp. 245-250. His last publication was the memoir, "Les Poissons Wealdiens de Bernisart," published in 1911 (*Mém. Musé. Roy. d'Hist. Nat. de Belgique*, VI., pp. iv + 65, 12 pls.).

Traquair had a specimen of *Palæospondylus* for years in his possession before publishing it to the world: he had apparently waited in the hope of being able to throw additional light on this elusive fossil.

The work of Dr. Traquair may be described as that of a morphologist working out anatomical structures as a key to relationships, rather than that of a systematist. Still he described, as one should, such new species as came his way—perhaps a hundred in all. His greatest service was in establishing clearly the limits and the relationships of certain of the larger groups, such as the lungfishes and the Actinopterygia, and in carrying their history back to the early Devonian. In his classic memoir on the Palæoniscidæ, he showed on evidence that is now accepted as incontrovertible—but which none the less was not at all evident before he took up these obscure fossils—that these fishes are related to the sturgeons, especially to such forms as *Polyodon*, and not, as previously believed, to the gar pikes. This conclusion was of far-reaching importance, leading to a modification of many other ideas of the inter-relationships of the groups of fishes. The flattened, compressed Platsysomidæ, he proved, are a specialized branch of the Palæoniscidæ; and he showed conclusively that *Cheirolepis* was a primitive ganoid, not an Acanthodian, and thus traced back the history of the acanthopterygian fishes almost as far back as that of any other group. He was the first to prove that the Devonian *Dipterus* was a lungfish, and thus he extended the geological history of this group. He gave us a revised study of the Arthrodire, *Coccosteus*, on which one or two restorations by other writers were subsequently based; and it was he who first clearly defined the characters of *Homosteus* and of *Phlyctenaspis*. He was the first to bring together our scattered knowledge of *Pterichthys* and to give a restoration of this form; and he, also, worked out the anatomy of that primitive type, *Drepanaspis*. To Traquair also must be credited whatever knowledge we possess of those extraordinary forms *Thelodus* and *Lanarkia*, which gave us the first conception of the appearance and the structure of the earliest known vertebrates. Dr. Traquair also

devoted considerable time to preparing monographs of the fishes of the Old Red Sandstone. These were published by the Paleontographical Society, and appeared in parts, as ready; these, unfortunately, are left unfinished.

These are only a few of the more far-reaching studies of Dr. Traquair which our limited space allows us to mention, but there was hardly a field of paleozoic ichthyology which he did not touch, and, as was well said by one of his biographers, he touched nothing that he did not adorn.

Personally, Dr. Traquair was a most charming man. In 1909 the writer had the privilege of seeing him almost daily at the museum or in his home. He was quiet and reserved in bearing, but he possessed a fund of humor that was all the more surprising because, on account of his quiet manner, it was not at first expected. One could not be with him many days without seeing that the man was far greater than his works. He had a deep appreciation for the beauties of nature. He had a great love for Scottish history and knew the legends concerning every name and place, whether it was Mons Meg or Holyrood Abbey. He was a most charming host, and the memory long lingers of having seen him the center of a circle at an afternoon tea, when he was the life of the whole company. He was very fond of flowers, and the artistically laid out rectangular garden, sloping down from the rear of the house at Colinton, near Edinburgh, gave him great delight, and he talked with genuine pleasure of its every plant. He was a student of modern languages, which were his hobby, and it was with amazement that one who knew only his work on fossil fishes heard him discourse, at length, on words and their history. He used to spend most of his vacations in Germany because of his great love for the language and for the ways of German savants; and he spoke the language fluently, and wrote it with a grace that is seldom achieved except in one's mother tongue.

Those who have known Dr. Traquair intimately are deeply grieved to have lost a wise and lovable friend.

AMERICAN MUSEUM OF NATURAL HISTORY

## JOHN SHAW BILLINGS

THE New York Library Club has adopted the following resolution:

*Resolved*, That on the death of John Shaw Billings, The New York Library Club desires to record its grateful recognition of the great part which he played in the development of the library service of New York City and of the United States.

While Dr. Billings gained distinction in the profession of his first choice in medical service during the Civil War, in the organization of the U. S. Marine Hospital Service and of the Johns Hopkins Hospital, as director of the University of Pennsylvania Hospital and professor of hygiene in that institution, as expert in charge of the division of vital statistics of the tenth and eleventh censuses, and as a writer upon medical subjects, it is as one of the most eminent members of our own profession that we honor his memory.

Called in 1895 to be director of the newly established New York Public Library, he gave an impetus to the growth of its collections almost without parallel in the history of libraries and ensured their permanent value by making the collections of government publications and periodicals his first object. He was instrumental in the establishment of a remarkable system of branch libraries and planned the unique library building which contains the library's reference collections and is the center of its circulation department. As members of this club we will honor Dr. Billings as the most distinguished of all those who have served the library interests of this community.

As librarians, however, we will remember also his remarkable achievements as librarian of the Surgeon General's Office, in the development of the largest medical library in the world, in the publication of the most important of medical bibliographies, the "Index Catalogue," as well as the most useful, the "Index medicus," and in the inauguration of a national library service.

And as bibliographers we will remember also his services as delegate of the United States to the congress held in London in 1896 which established the International Catalogue of Scientific Literature.

He was a member of this club and its president in the year 1900, a member of the American Library Association and its president in the year 1902, a member of many learned societies, honored by learned institutions and societies, both at home and in foreign lands.

He gave to his profession the service of a scientist interested in the most common problems, the labors of a specialist with the broadest sympathies.

THE CARNEGIE FOUNDATION FOR THE  
ADVANCEMENT OF TEACHING<sup>1</sup>

THE seventh annual report of the president and treasurer of the Carnegie Foundation, which has just appeared, covers the year ended September 30, 1912.

The endowment in the hands of the trustees at that time amounted to approximately \$14,000,000, and the income for the year amounted to \$676,486, of which \$634,497 was expended. From its first pension payment in June, 1906, to the end of the fiscal year September 30, 1912, the foundation has distributed \$2,077,814 in retiring allowances to professors and \$238,590 in widows' pensions—a total of \$2,316,404. In all 429 retiring allowances and 90 widows' pensions have been granted, of which 98 have terminated through death and 23 at the expiration of temporary grants, leaving 315 retiring allowances and 83 widows' pensions in force at the end of the year.

The report of the president, like the former reports, is divided into two parts—the first referring to the current business of the year and dealing with questions more directly pertaining to the administration of the foundation; the second part being devoted to current educational problems of a larger and more general nature.

The first part of the report includes a careful statement of the whole question of pensions for teachers, for government employees and for industrial employees. This statement contains the results of the examination of practically all of the pension systems now in operation anywhere, and leads finally to a discussion of a feasible pension system for the public school teachers of a state. This discussion is particularly needful at this time, since the question of teachers' pensions is a matter under consideration by a number of state legislatures. As the report points out, the bills which have been introduced in the various legislatures almost without exception

<sup>1</sup> Official summary sent by the foundation.

violate fundamental actuarial conditions, and have been framed without study of the essential conditions which must be fulfilled by any adequate pension system. The material brought together in this report, the examples of the failures of pension systems which have occurred—as, for example, that in New South Wales—and the precarious situation in which many state pension systems now stand, make this portion of the report one of great practical value to the authorities of any state contemplating pensions either for teachers or for state employees.

President Pritchett, in arguing finally for some form of contributory pension system for public school teachers, points out clearly the difficulties of the contributory system, the necessity for the most careful actuarial advice and the public nature of the questions which are involved in a distribution of the cost of such a pension system between the state and the teacher.

Following the discussion of these pensions, a complete history of the methods by which the Carnegie Foundation pensions were arrived at is given; the process through which the trustees worked is told in the frankest manner; the difficulties which they encountered and the differences which arose out of the fact that the pensions of the Carnegie Foundation are not contributory, but have come as the result of a free gift, are made clear. The literature on pensions now at the disposal of the foundation is probably the most complete in the statement of such problems that has ever been brought together, and the discussion here made can not fail to be of value to a college, a state or an industrial association which is studying the pension problem; and the pension problem to-day is one of the insistent problems of modern social progress.

The second part of the report is devoted to such subjects as the matter of college entrance requirements, admission to advanced standing, a statement of medical progress, university and college financial reporting, advertising as a factor in education, education and politics, and finally, sham universities.

All of these subjects are discussed in the

frank and specific manner which has hitherto been used in these reports. In recounting the extraordinary medical progress of the last five years attention is called to the connection which still exists in the United States between reputable colleges and unworthy medical schools. The lessons of the recent Bulletin on Medical Education in Europe are also brought clearly forward. During the last five years the mortality among unworthy medical schools has been most satisfactory. The number of such schools in the United States has been reduced by about one third and the number of students attending them by about one quarter, and this diminution has occurred in exactly the places where it ought to occur—namely, in the elimination of the unfit.

The section devoted to education and politics discusses not only the recent remarkable changes in the University of Oklahoma, the University of Kentucky and the University of Montana, but also deals with two other tendencies in political life which are profoundly affecting education: first, with the rivalry which comes from competing state institutions, and secondly with the practise inaugurated almost wholly within the last ten years in states where there are no state universities, of subsidizing institutions that are under private control. In a number of states this process has gone on until it has enormously increased the number of privately controlled institutions which share in state appropriations. So marked has this tendency become that the question of state appropriation to education without state control is one which ought now to be frankly and squarely met.

Under sham universities the report deals with conditions such as hold, for example, in the District of Columbia, where commercial enterprises without endowment or facilities are chartered as educational institutions under the loosest conditions, which enable them to appeal to the credulity of ignorant students throughout this and other countries under high-sounding names and under the shelter of charters granted by the general government. A bill now before Congress aims to correct this situation.

The report will be sent upon request to the Carnegie Foundation, 576 Fifth Avenue, New York City.

#### THE PACIFIC ASSOCIATION OF SCIENTIFIC SOCIETIES

THE third annual meeting of the Pacific Association of Scientific Societies will be held at the University of California, Berkeley, April 10-12. The number of constituent societies has increased to fourteen, representing a membership of 2,167.

The Technical Society of the Pacific Coast,  
The Cordilleran Section of the Geological Society of America,  
The Seismological Society of America,  
Pacific Coast Branch of the American Historical Association (not meeting),  
The Pacific Slope Association of Economic Entomologists,  
Pacific Coast Paleontological Society,  
The Philological Society of the Pacific Coast,  
The Cooper Ornithological Club,  
California Academy of Sciences (not meeting),  
Biological Society of the Pacific Coast,  
California Section of the American Chemical Society,  
Astronomical Society of the Pacific,  
The Geographical Society of the Pacific (not meeting),  
Puget Sound Section of the American Chemical Society.

The San Francisco Section of the American Mathematical Society will also hold its annual meeting at the University of California on April 12.

The Le Conte Club will hold its annual meeting and dinner at the Faculty Club, Friday evening, April 11.

The General Session of the Pacific Association will be held in California Hall on Saturday evening when an address of welcome will be given by President Benjamin Ide Wheeler, of the University of California. Three papers of general scientific interest will be read by representative members of the constituent societies.

The Southern Pacific, Santa Fe, Western Pacific, Oregon-Washington, Great Northern and Northern Pacific Railroads, have granted

the usual convention rates for the states of Nevada, California, Oregon and Washington.

#### SCIENTIFIC NOTES AND NEWS

THE spring meeting of the council of the American Association for the Advancement of Science will be held at the Cosmos Club, Washington, D. C., on the afternoon of Tuesday, April 22, 1913, at 4:45 o'clock.

THE issue of *Nature* for March 6 contains a portrait of Sir J. J. Thomson, with an appreciation of his contributions to physics by Augusto Righi, professor of experimental physics in the University of Bologna.

To celebrate the seventieth birthday of Dr. Paul Groth, professor of mineralogy in the University of Munich and editor of the *Zeitschrift für Crystallographie*, it is planned to place a bronze bust in the Mineralogical Institute of the University of Munich. Dr. G. Seligmann, of Coblenz on the Rhine, is treasurer of the committee.

THE senate of the University of Dublin has approved the conferment of the honorary degree of doctor of science upon Professor A. C. Seward, F.R.S., and Professor the Hon. R. J. Strutt, F.R.S.

THE degree of M.A. has been conferred by a decree of convocation of the University of Oxford on Professor W. H. Perkin, F.R.S., fellow of Magdalen College, the recently elected Waynflete professor of chemistry.

MR. A. HARKER has been nominated to represent the University of Cambridge at the twelfth International Geological Congress to be held in Canada in August next.

THE Geological Society of France has awarded its Gaudry medal to Professor Edward Suess, of the University of Vienna.

IT is stated in *Nature* that the founder's royal medal of the Royal Geographical Society is not awarded this year, but a casket with a suitable inscription will be presented to Lady Scott, to contain the patron's medal and the special Antarctic medal awarded to her late husband, Captain R. F. Scott, in 1904. The patron's medal has been awarded to the late Dr. E. A. Wilson, of the National Antarctic

expedition, and a gold watch to Lieutenant Campbell, who led the northern party of the same expedition. The Victoria medal is awarded to Colonel S. G. Burrard, F.R.S.; the Gill memorial to Miss Lowthian Bell; the Murchison award to Major H. D. Pearson; the Cuthbert Peek grant to Dr. Felix Oswald; and the Back bequest to Mr. W. S. Barclay.

THE position of chief of the Forest Service, now held by Professor Henry S. Graves, who succeeded Mr. Gifford Pinchot, has been placed under the classified civil service. The position will become vacant only on voluntary resignation or on removal for failure to carry out properly the duties of the office.

THE expedition to explore the regions of the Amazon left Philadelphia for the south on the yacht *Pennsylvania* on March 19. The expedition is being made under the auspices of the University of Pennsylvania Museum, and will extend over a period of three years. The leader of the expedition is Dr. William C. Farrabee, curator of the American section of the museum. The yacht is in command of Dr. J. H. Rowen, a retired officer of the U. S. Navy. The other members of the expedition are: Dr. Franklin B. Church, who will make a special study of tropical diseases, and Mr. Sandy McNabb, a traveler of wide experience.

PROFESSOR W. A. HENRY, emeritus professor of agriculture of the University of Wisconsin and for many years dean of the College of Agriculture, is on his way back from a trip to Panama, Jamaica and Cuba. He will spend some time at his large peach farm near Wallingford, Conn.

THE Cutter lectures on preventive medicine and hygiene will be given at the Harvard Medical School by George C. Whipple, professor of sanitary engineering, Harvard University, on "The Use of Vital Statistics." The dates and subjects are: March 31, "With Truth"; April 2, "With Imagination"; April 5, "With Power."

BEFORE the Geographic Society of Chicago, on March 28, at Fullerton Hall, a lecture was given by Professor Merritt L. Fernald, of

Harvard University, the title being "The Mountains and Barrens of Newfoundland and the Gaspé Peninsula."

MR. F. E. MATTHES, of the U. S. Geological Survey, gave a lecture on March 18 before the Appalachian Mountain Club of Boston on "The Glaciers of Mount Rainier." On March 19 he repeated this lecture at Wellesley College. On March 20 he spoke to the classes in civil engineering and mining of the Massachusetts Institute of Technology on "The Sculpture of the Yosemite Valley and the manner in which it is brought out on the Yosemite Map." On March 22 he spoke to the classes in civil engineering, mining and geology of Dartmouth College on the "Delineation of Land Forms as Exemplified by the Map of the Yosemite Valley."

VLADIMIR KARAPETOFF, professor of electrical engineering at Cornell University, will address students at four southern colleges, namely, Clemson College, S. C., on April 2; Georgia School of Technology at Atlanta, on April 4; Alabama Polytechnic Institute in Auburn, on April 7, and University of Tennessee at Knoxville, on April 10. In each of these places he is scheduled for three events: a lecture for electrical students on electrostatic and magnetic circuits, a general address on the development of personality and a lecture-recital on musical expression.

A MEMORIAL window to Ralph Stockman Tarr, late professor of physical geography in Cornell University, who died March 20, 1912, was dedicated in Sage Chapel last week. The window was unveiled by Professor Lawrence Martin, of the University of Wisconsin, formerly an assistant under Professor Tarr. Acting President Crane accepted the memorial on behalf of the university.

DR. IRA VAN GIESON, formerly instructor in pathology in Columbia University, and at one time director of the New York State Pathological Institute, died in New York City on March 24.

DR. PRINCE ALBERT MORROW, the eminent dermatologist of New York City, died on March 17, aged sixty-six years.

DR. E. G. RAVENSTEIN, who did much to improve cartographical methods in Great Britain, has died at the age of seventy-nine years.

DR. F. HOWITZ, formerly professor of gynecology in the University of Copenhagen, has died at the age of eighty-four years.

The deaths are also announced of Professor G. Vassale, who held the chair of general pathology at the University of Modena, and of Professor Albanese, who held the chair of pharmacology at Rome.

THE U. S. Civil Service Commission announces examinations towards the end of the month for assistant chemist in the office of public roads at salaries ranging from \$1,800 to \$2,200; for examiner of surveys in the Forest Service, at salaries of from \$1,200 to \$1,500, and of preparator of fossils in the Geological Survey, at a salary of \$900.

By the recent British insurance act it is provided that one penny per insured person, payable out of the moneys provided by parliament, may be retained by the insurance commissioners to be applied for the purposes of research, and the total sum thus available will at present amount to about £57,000 per annum. While the main concern of this part of the act is to combat tuberculosis, the commissioners have been advised that the money may properly be applied to research in connection with any disease which may affect insured persons.

By the will of Carl H. De Silver, of Brooklyn, the Brooklyn Institute of Arts and Sciences receives \$50,000.

THE twentieth semi-annual meeting of the Association of Teachers of Mathematics in the Middle States and Maryland was held at the University of Pittsburgh on March 22.

THE fifth annual meeting of the Illinois Water Supply Association was held at the University of Illinois on March 11 and 12. The membership of the association is made up of waterworks engineers, superintendents, chemists, and others interested in obtaining and conserving an abundant supply of pure water. The papers read at this meeting cov-

ered a wide range of subjects, including the study of deep well drillings in Illinois, sterilization of water by ultra-violet light, filter plants, practical methods of obtaining efficiency in waterworks pumping plants, bacterial examination of water supplies, conditions in small filter plants, appraisal of waterworks properties, fire streams and municipal laboratories. About one hundred and twenty-five members attended the meeting. The officers elected for the next year are: President, C. H. Cobb, superintendent, Kankakee Waterworks; First Vice-president, H. M. Ely, superintendent and manager, Danville Water Company; Second Vice-president, W. J. Spaulding, commissioner of Public Property, Springfield; State Vice-president, V. E. MacDonald, superintendent, Lincoln Water and Light Company, and secretary and treasurer, Professor Edward Bartow, director, State Water Survey.

A room in the Geological Museum of Harvard University has been fitted with cases for twelve relief maps and models which have been recently acquired. One of these is a copy of the model of the Mt. Sentis, on the borders of the Swiss cantons St. Gall and Appenzell. This model was done by Mr. G. C. Curtis, '96, and took first prize at the World's Exposition in Paris in 1900. There is also a relief map of southern New England done by Mr. Edwin E. Howell.

A TOTAL working income of approximately \$35,000,000 was received by 87 state universities and other state-aided institutions of higher education during the past year, as shown by a bulletin just issued by the United States Bureau of Education. Of this amount the United States government contributed about \$5,000,000 and the states \$18,000,000. The year's income passed the two million mark in the case of three state universities. The University of Illinois had an income during 1911-12 of \$2,363,711; the University of Minnesota, \$2,682,499; and the University of Wisconsin, \$2,122,297. Cornell University, which is technically a private institution but receives state and federal aid, reported total

receipts of over three million dollars with a net income available for current expenses of about a million and a half. Several other state-aided institutions are in the million-dollar income class. These include the University of Michigan, which had an income of \$1,343,057; Ohio State University, with \$1,011,571; and the University of California, with \$1,711,393. The latter had an additional half million from private benefactions. The state of Iowa supports several institutions of college and university rank with a combined income of over two million dollars. Some of the states are exceedingly generous to their colleges and universities, and in such cases the national government's contribution is only a small fraction of the total. Illinois meets the government's \$80,000 with nearly two million dollars from state funds, and there are several other states that are similarly liberal. Most of the states give to higher education a greater sum than they receive from the United States government. On the other hand, a few states depend to a considerable extent upon Uncle Sam's bounty. The state of Delaware provided \$22,000 last year for Delaware College, to accompany the \$70,000 received from federal funds; in Maryland the state itself furnished \$36,000 for the Agricultural College, against \$80,000 received from the federal government; New Hampshire's contribution to the State College was \$20,955; and the state of Vermont gave only \$26,000 out of a total income of \$277,815 reported by the state university, while \$80,000 was derived from the United States government and \$60,958 from private benefactions. In some of the larger state-aided universities, tuition fees from students have become an important factor in the annual income; and others that are to a certain extent public institutions have private benefactions that yield a permanent working revenue. Thus the University of Vermont has considerable endowment; Massachusetts Institute of Technology, though aided somewhat by state and national government, depends for the bulk of its income upon the students' fees and private funds; and Cornell University received nearly half a million from

each of three sources, namely, students' fees, productive funds and state appropriations.

#### UNIVERSITY AND EDUCATIONAL NEWS

THE legislature of Missouri, at its biennial session, has appropriated for the support and buildings of the University of Missouri during 1913-14 \$1,417,500. Included in this are appropriations of \$200,000 towards a library building; \$100,000 for a biological laboratory, and \$25,000 for a live stock judging pavilion. In addition to the above the Agricultural College, which is a part of the university, receives \$142,000. Of this appropriation \$50,000 is for hog cholera serum; Agricultural Experiment Station, \$30,000; county farm advisers, \$25,000; soil experiment fields, \$20,000; state soil survey, \$12,000, and Corn Growers' Association, \$5,000.

MESSRS. ANDREW W. MELLON and Richard B. Mellon, of Pittsburgh, have announced their purpose to erect on the campus of the University of Pittsburgh a laboratory for the department of industrial research to cost not less than \$150,000, to equip the same, and provide a fund of \$40,000 per annum for the coming five years for its maintenance. This department of the university is under the immediate care and oversight of Dr. Robert Kennedy Duncan, the well-known leader in industrial research.

A HOLDING trust has been formed in Massachusetts called the Harvard Mutual Foundation. It will receive gifts from those desiring to leave money to Harvard University, pay 5 per cent. interest to the donor or his immediate heirs during their lives, and at their deaths turn over the principal to the university. The fund starts with \$250,000. The foundation is controlled by the university, in that its trustees will be named by the corporation, and that body will have a certain voice in the management of the trust. The first trustees are the following: Charles Francis Adams, 2d, '88, treasurer of the university; T. N. Perkins, '91; Arthur Lyman, '83; George U. Crocker, '84; John C. Cobb, Jr., '00; Alexander H. Ladd, '97, and O. H. W. Foster, '81.

In 1909 the Goldsmiths Company gave £50,000 towards the extension of the engineering department in the Central Technical College, London. We learn from *Nature* that the company has now offered to pay the entire cost of the new building, which means an added gift of £37,000. The Goldsmiths' Company has attached the condition that the portion of the capital belonging to the Imperial College of Science and Technology, which will be thus set free, shall be added to the endowment fund, the income being used for higher educational and research work.

THE union of the University of Maryland medical department and the Baltimore Medical College is assured, the faculties having agreed on the terms of merger. Members of the faculty of the latter institution will retain their positions in the new school and three of them will become members of the university board of regents.

THE amalgamation of the two medical schools in Richmond, Va., has now been consummated. On March 22 the following appointments to the faculty were made by the board of visitors:

#### *Professors*

W. G. Christian, anatomy.  
 W. A. Shepherd, histology and embryology.  
 Wortley F. Rudd, chemistry.  
 Alfred L. Gray, physiology.  
 S. B. Moon, pathology (acting).  
 Francis W. Upshur, pharmacology and therapeutics.  
 William S. Gordon, medicine.  
 McGuire Newton, pediatrics.  
 Beverly R. Tucker, neurology and psychiatry.  
 E. P. McGavock, dermatology.  
 George Ben Johnston, surgery.  
 Lewis C. Bosher, genito-urinary surgery.  
 Joseph A. White, ophthalmology.  
 John Dunn, otology, rhinology and laryngology.  
 John F. Winn, obstetrics.  
 Charles R. Robins, gynecology.  
 Edward McGuire, clinical medicine.  
 Manfred Call, clinical medicine.  
 J. Allison Hodges, clinical neurology and psychiatry.  
 Stuart McGuire, clinical surgery.  
 Hugh M. Taylor, clinical surgery.

#### *Associate Professors*

John W. Brodnax, anatomy.  
 E. C. L. Miller, chemistry (physiological).  
 C. Howard Lewis, physiology.  
 E. Guy Hopkins, pathology (clinical).  
 Aubrey H. Straus, bacteriology.  
 Ennion G. Williams, hygiene and public health.  
 Leslie B. Wiggs, materia medica and pharmacology.  
 A. G. Brown, medicine (theory and practise).  
 J. McCaw, Thompson, medicine (theory and practise).  
 J. Garnet Nelson, medicine (physical diagnosis).  
 Dougless van der Hoof, clinical medicine.  
 St. George T. Grinnan, pediatrics.  
 Roshier W. Miller, neurology and psychiatry.  
 G. Paul La Roque, surgery (practise).  
 James W. Henson, surgery (principles).  
 A. Murat Willis, surgery (operative).  
 William W. Dunn, surgery (minor).  
 W. Loundes Peple, clinical surgery.  
 William P. Mathews, orthopedic surgery.  
 R. C. Bryan, genito-urinary surgery.  
 R. H. Wright, ophthalmology.  
 S. C. Bowen, otology and rhinology.  
 Clifton M. Miller, laryngology.  
 Greer Baughman, obstetrics.  
 Stuart Michaux, gynecology.

Twenty-seven of these men were formerly connected with University College of Medicine and nineteen with the Medical College of Virginia.

PROFESSOR IRA N. HOLLIS, since 1893 professor of engineering at Harvard University, has accepted the invitation of the trustees of the Worcester Polytechnic Institute to become president of that institution.

PROFESSOR W. C. RUEDIGER, who has been acting dean of the Teachers College at the George Washington University since the death of Dean Hough last September, has been appointed dean.

PROFESSOR JORES, of Cologne, has been appointed director of the Institute of Pathology at Marburg.

PROFESSOR LUBARSCH, of Düsseldorf, has succeeded the deceased Professor Heller as director of the Institute of Pathology at Kiel.

## DISCUSSION AND CORRESPONDENCE

## THE COMPLEXITY OF THE MICROORGANIC POPULATION OF THE SOIL

DURING the last few years a series of experiments have been carried out in this laboratory by Dr. Hutchinson and myself<sup>1</sup> which we can only interpret as showing that bacteria are not the only active inhabitants of the soil. The results in our view point conclusively to the presence of another group of organisms, detrimental to bacteria and differing from them by their larger size, slower rate of multiplication under soil conditions, and lower power of resistance to heat and antiseptics. They are, therefore, more readily killed than bacteria, and we regard their suppression as an important factor in bringing about the increased bacterial activity known to set in after soil has been partially sterilized or treated in any other way detrimental to active life. Such properties as we could ascertain agree with those of protozoa; we were thus led to look for these organisms in the soil and found numbers of them. We adduced reasons for provisionally identifying the detrimental organisms with the soil protozoa.

Recently several papers have been published in the United States controverting these conclusions. We are not satisfied, however, that the criticisms affect the validity of our arguments, and therefore desire to set out briefly the experimental facts and the conclusions we draw from them. The actual data are to be found in our papers in the *Journal of Agricultural Science*; many of the figures were also presented to the Graduate School of Agriculture at East Lansing last July.

1. We begin with the fact that partial sterilization of soil, *i. e.*, heating it to a temperature of 60° C. or more, or treatment for a short time with vapors of antiseptics such as toluene, causes first a fall and then a great rise in bacterial numbers. The rise sets in soon after the antiseptic has been removed and the soil conditions once more made favor-

able for bacterial development; it goes on till the numbers far exceed those present in the original soil.

2. Simultaneously there is a considerable increase in the accumulation of ammonia. This sets in as soon as the bacterial numbers begin to rise, and the connection between the two quantities is normally so close as to indicate a causal relationship; the increased ammonia production is, therefore, attributed to the increased numbers of bacteria. There is no disappearance of nitrate; the ammonia is formed from organic nitrogen compounds.

3. The increase in bacterial numbers is the result of improvement in the soil as a medium for bacterial growth and not an improvement in the bacterial flora. Indeed the new flora *per se* is less able to attain high numbers than the old. This is shown by the fact that the old flora when reintroduced into partially sterilized soil attains higher numbers and effects more decomposition than the new flora. Partially sterilized soil *plus* 0.5 per cent. of untreated soil soon contains higher bacterial numbers per gram and accumulates ammonia at a faster rate than partially sterilized soil alone.

4. The improvement in the soil brought about by partial sterilization is permanent; the high bacterial numbers being kept up even for 200 days or more. The improvement, therefore, did not consist in the removal of the products of bacterial activity, because there is much more activity in partially sterilized soil than in untreated soil. Further evidence is afforded by the fact that a second treatment of the soil some months after the first produces little or no effect.

It is evident from (3) and (4) that the factor limiting bacterial numbers in ordinary soils is not bacterial, nor is it any product of bacterial activity, nor does it arise spontaneously in soils.

5. But if some of the untreated soil is introduced into partially sterilized soil the bacterial numbers, after the initial rise (see (3)), begin to fall. The effect is rather variable, but is usually most marked in moist soils that have been well supplied with organic ma-

<sup>1</sup> *Journal of Agricultural Science*, 1909, 3: 111-144; 1912, 5: 27-47, 86-111; 1913, 5: 152-221.

nures; *e. g.*, in dunged soils, greenhouse soils, sewage farm soils, etc. Thus the limiting factor can be reintroduced from untreated soils.

6. Evidence of the action of the limiting factor in untreated soils is obtained by studying the effect of temperature on bacterial numbers. Untreated soils were maintained at 10°, 20°, 30° C., etc., in a well moistened aerated condition, and periodical counts were made of the numbers of bacteria per gram. Rise in temperature rarely caused any increase in bacterial numbers, sometimes it had no action, often it caused a fall. But after the soil was partially sterilized the bacterial numbers showed the normal increase with increasing temperatures. Similar results were obtained by varying the amount of moisture but keeping the temperature constant (20° C.). The bacterial numbers in untreated soil behaved erratically and tended rather to fall than to rise when the conditions were made more favorable to trophic life; on the other hand, in partially sterilized soil, the bacterial numbers steadily increased with increasing moisture content. Again, when untreated soils are stored in the laboratory or glass-house under varying conditions of temperature and of moisture content the bacterial numbers fluctuate erratically; when partially sterilized soils are thus stored the fluctuations are regular.

7. When the curves obtained in (6) are examined it becomes evident that the limiting factor in the untreated soils is not the *lack* of anything<sup>2</sup> but the *presence of something active*.

8. This factor, as already shown, is put out of action by antiseptics and by heating the soil to 60° C., and once out of action it does not reappear. Less drastic methods of treating the soil put it out for a time, but not permanently: *e. g.*, heating to 50°, rapid drying at 35°, treatment with organic vapors less toxic than toluene (*e. g.*, hexane), incomplete treatment with toluene. In all these cases the rise induced in the bacterial numbers per

gram is less in amount than after toluene treatment and is not permanent; the factor sets up again. As a general rule, if the nitrifying organisms are killed, the limiting factor is also extinguished; if they are only temporarily suppressed the factor also is only put out for a time.

9. The properties of the limiting factor are: (a) It is active and not a lack of something (see (7)); (b) it is not bacterial (see (3) and (4)); (c) it is extinguished by heat or poisons and does not reappear if the treatment has sufficed to kill sensitive and non-spore-forming organisms; it may reappear, however, if the treatment has not been sufficient to do this; (d) it can be reintroduced into soils from which it has been permanently extinguished by the addition of a little untreated soil; (e) it develops more slowly than bacteria and for some time may show little or no effect, then it causes a marked reduction in the numbers of bacteria, and its final effect is out of all proportion to the amount introduced; (f) it is favored by conditions favorable to trophic life in the soil.<sup>3</sup>

10. We see no escape from the conclusion that the limiting factor is a living organism. We were, therefore, led to search for organisms not bacteria, slower growing, less resistant and larger. Protozoa naturally suggested themselves. We soon found numbers of ciliates, amœbæ and flagellates and induced Mr. Goodey to study them in detail. This work is still continuing, and promises highly interesting results: some remarkable forms have been picked out, and it is already evident that the zoological survey of the soil will be a prolonged business but will be eminently worth while. The ciliates and amœbæ are killed by partial sterilization. *Whenever they are killed the detrimental factor is found to be put out of action*, the bacterial numbers rise and maintain a high level. Whenever the detrimental factor is not put out of action the protozoa are not killed. To these rules we have found no exception. Some exceptions have been found to the converse proposition,

<sup>2</sup> The soils we used included fertile loams well supplied with organic matter, calcium carbonate, phosphates, etc.

<sup>3</sup> This is dealt with fully in the *Journal of Agricultural Science*, 1912, 5: 27, 86.

i. e., we have sometimes found ciliates and amœbæ in soils in which the detrimental factor had been put out of action, but our present methods do not enable us directly to discriminate between protozoan cysts and active forms, nor to estimate the numbers present, nor, on the other hand, to determine how completely the detrimental factor is put out of action. But in general the parallelism between the detrimental factor and the soil protozoa is so complete that we are justified in provisionally regarding protozoa as the detrimental organisms we have been seeking.

Such is a short statement of the main lines of the work. I have omitted the subsidiary issues: the vain search for bacterio-toxins,\* for evidence of bacterial stimulus, of improvements in the bacterial flora, etc. The identification of the detrimental organisms with the soil protozoa is provisional only; in the nature of the case a rigid proof would be very difficult even if it were possible.

I now turn to some of the criticisms that have been passed on this work by my American colleagues. Dr. Jacob G. Lipman at the New Jersey Station, in conjunction with Messrs. Blair, Owen and McLean, carried out some experiments,<sup>6</sup> the results of which they consider to be in direct opposition to ours. They added pasteurized and untreated soil infusions respectively to mixtures of dried blood and sterilized soil (heated under a pressure of 1.5 atmospheres of steam). After seven days the pasteurized infusions had induced the formation of no more ammonia than the untreated infusion. These results, they say, "do not bear out Russell and Hutchinson's contention as to the part played by protozoa in depressing the activities of soil bacteria."

\*This result is not necessarily in contradiction with those obtained by the Bureau of Soils. I understand that Dr. Schreiner's toxin is obtained from badly drained, badly aerated soils deficient in calcium carbonate: our soils, on the other hand, were well drained, well aerated and well supplied with calcium carbonate.

<sup>6</sup> Bull. 248, 1912.

The argument is ingenious, but it does not appear to us to bear on the question. In the first place, soil sterilized by heating under a pressure of 1.5 atmospheres has undergone very considerable decomposition. We have obtained evidence that such highly heated soil is altogether different from normal soil as a medium for the growth of microorganisms. Failure of protozoa to develop in the highly heated soil would be no evidence at all of their inability to develop in ordinary soil. As a matter of fact the nitrifying organisms do not seem to have developed; would Dr. Lipman argue that the results "do not bear out the usual contention as to the part played by the nitrifying organisms in the soil"? Secondly, even if the detrimental organisms could develop in highly heated soil they were not given the chance: we have never observed any development in anything like so short a period as seven days, our experiments have always been continued much longer. Lastly, the action of the detrimental organisms is to keep down the numbers of bacteria. Now the rate of ammonia production is not necessarily a measure of bacterial numbers and therefore affords no rigid test of the activity of the detrimental organisms.

Dr. G. E. Stone, of the Massachusetts Experiment Station,<sup>7</sup> who has had great experience of soil sterilization and informs us that he has "experimented with practically everything there is in this line," is convinced that protozoa "have little or no part in accounting for the increased number of bacteria in our soils." The evidence is based on some experiments by Messrs. Lodge and Smith. Decoctions were made of untreated soil and of soil heated for 45 minutes to 250° F.; into each of these decoctions soil bacteria were introduced. Greater bacterial development occurred in the decoction of the sterilized soil than in the decoction of the untreated soil. (A subsoil behaved differently.) The authors state that protozoa were absent and that the results must be due to other causes. With this I entirely agree; a decoction of a highly

<sup>7</sup> Twenty-fourth Annual Report, 1912.

heated soil is manifestly very different from a decoction of untreated soil; it contains much larger quantities of dissolved substances and may be expected to behave differently as a medium for bacterial development. The experiment proves conclusively that heating a soil to 250° F. causes decomposition, but I can not see that it helps us to find out what is going on in an unheated soil. The authors go on to say that protozoa are "uncommon in their soils" and "very few forms were found." It would be interesting to find what is the difference between their soil conditions and those at Michigan where Dr. Rahn<sup>1</sup> found protozoa of the same types occurring in numbers of the same order per gram as we find at Rothamsted.

Professor G. T. Moore, writing in *SCIENCE*,<sup>2</sup> disagrees wholly and absolutely with our work; indeed he thinks that in the tangled maze of microbiological problems "the one fact which does seem to be fairly well established is that the temporary removal from the soil of the protozoa has but little bearing on the problem." We should not feel that we had lived in vain if we had merely been the humble instruments by which such a proposition was established, but again we are not satisfied as to the evidence. Professor Moore asserts that soil protozoa are not killed by toluene, carbon disulphide, etc., but are only temporarily depressed, and after three days their numbers may equal or even exceed those originally present. Never on any occasion have we observed anything of this kind.

In an admirable paper<sup>3</sup> on the effects of heat on the soil Drs. Seaver and Clark attribute to us the claim that the increased productiveness of heated soils is due to the destruction of protozoa. We wish to point out that we have always regarded the destruction of detrimental organisms as only one factor in the case, and have fully recognized the effects of the decomposition brought about by the heat. In order to minimize these decomposition effects we generally treat our soils

with vapors of antiseptics rather than by heat, but here also we do not lose sight of the possibility of other changes being induced besides the destruction of life.

Finally, we may be allowed to remind the reader that the adverse effect of our detrimental organisms is on the numbers of bacteria, but that the relationship of bacterial numbers to soil fertility is by no means simple. Fertility is determined by any of the factors capable of limiting plant growth. In some soils it may be the supply of phosphates, of potash, of water that is inadequate; if so, soil bacteria may show little or no connection with fertility. Only when the supply of nitrogen compounds becomes a limiting factor do the soil bacteria come in, and even then the relationship between their numbers and their activity is not quite straightforward. We have traced out this problem in detail in our paper in the *Journal of Agricultural Science*, 1913, p. 152.

We do not underrate the complexity of soil fertility problems and, above all, we do not assert that our destructive organisms are the only things involved in the matter, but we do claim that they are an important factor. Our only hope of getting any further with the complex problems of the soil is to study the factors one at a time. We must not be confused by the circumstances that other factors remain to be studied, nor, on the other hand, must we lose sight of the possibility that these other factors may vitiate some of our experiments.

#### TWO ADDITIONS TO THE MAMMALIAN FAUNA OF MICHIGAN

THE northern pine vole, *Microtus pinetorum scalopsoides* (Audubon and Bachman) has apparently not been recorded from Michigan, and up to last year no Michigan specimen had been secured by the museum. In April, 1912, a specimen (No. 42,558, Museum of Natural History, University of Michigan) was taken by W. A. Brotherton, near Rochester, Oak-

<sup>1</sup> *Centr. Bakt. Par.*, 1913, 36: 419-421.

<sup>2</sup> November 8, 1912.

<sup>3</sup> *Biochemical Bulletin*, 1912, 1: 413.

land County, and since that time the writer has examined two specimens from the collection of the Michigan Agricultural College, both of which were secured near East Lansing, one on April 20, 1901, by D. S. Bullock, and the other in August, 1896, by T. L. Hankinson.

Another species apparently new to the Michigan fauna is Richardson's shrew, *Sorex richardsonii* Bachman, a specimen of which, taken at Chatham, Alger County, August 28, 1900, is in the collection of the Michigan Agricultural College. Although Seton<sup>1</sup> includes the northern peninsula in his map of the range of the species, the writer can find no recorded localities nearer than Oneida County, Wisconsin,<sup>2</sup> and the north shore of Lake Superior. Northern Michigan has probably been included in the range because this region formed a part of the "Northwest Territory"; it is not included by Merriam.<sup>3</sup>

The museum is indebted to the U. S. Biological Survey for verifying the identification of the specimens mentioned, and to Professor W. B. Barrows, for the loan of the specimens in the Michigan Agricultural College.

UNIVERSITY OF MICHIGAN

#### INTERGLACIAL RECORDS IN NEW YORK

IN Professor H. L. Fairchild's most interesting address on "Pleistocene Geology of New York State" the following statement appears:<sup>1</sup>

The accepted facts of multiple glaciation in the Mississippi basin coupled with proofs of Pre-wisconsin drift in Pennsylvania and New Jersey and on Long Island, with accumulating evidences in New England, demands the theoretical acceptance of at least dual glaciation for New York state. But the positive proof, in the field, of a Pre-wisconsin ice sheet has not been found.

<sup>1</sup>"Life Histories of Northern Animals," Vol. II., p. 1107.

<sup>2</sup>Hartley H. T. Jackson, *Bull. Wisconsin Natural History Society*, 1908, pp. 30-31.

<sup>3</sup>"North American Fauna," No. 10, p. 48.

<sup>4</sup>SCIENCE, XXXVII., No. 946, p. 238.

A few years ago, Miss Maury<sup>2</sup> reported an interglacial deposit at the south end of Cayuga Lake, on the west shore between "Taughan-nock Falls and Frontenac Beach in a small ravine which has cut through one of the delta terraces so common in Cayuga Valley." An exposure gave the following vertical section:

Drift .....	20 to 30 feet.
Gravel and sand .....	several inches.
Fossiliferous clay .....	10 to 15 feet.
Boulder clay .....	10 to 15 feet.
Devonian shales .....	10 feet above lake level.

The lower boulder clay is thought to represent the Illinoian invasion and is oxidized, indicating a period of exposure to the air and hence of erosion. The lower deposits are peaty and contain a quantity of plant remains. The upper fossiliferous deposits are a slaty blue clay in which mollusks to the number of eighteen species are found in abundance. Twelve of these molluscan species are also found in the interglacial Don beds of Toronto, and the lake in which these animals lived was doubtless contemporaneous with the large Ontario Lake in which the Don mollusks lived. The thickness of the clay deposits (10-15 feet) indicates a long period of deposition.

In the Watkins Glen-Catatonk Folio of New York,<sup>3</sup> page 26, reference is made to an older drift in Watkins Glen, underlying 100 feet of Wisconsin drift. In the blue clay underlying the drift and overlying a bed of sand and gravel, the leaf of an arctic willow (*Salix reticulatus*) was found. Though this deposit is stated by the authors to have probably been laid down during the advance of the Wisconsin ice sheet, the inference is strong, in view of the Cayuga Lake and the Toronto interglacial deposits, in favor of its being contemporaneous with the Scarboro beds near Toronto which contain cold climate animals and plants, including an undermined willow (*Salix* sp.). The evidence of this Cayuga Lake deposit appears to be quite as conclusive as is that of the Toronto deposits.

<sup>2</sup>*Journal of Geology*, XVI., pp. 565-567, 1908.

<sup>3</sup>Geologic Atlas, No. 169, 1909.

It is quite probable that well records in western New York will supply additional interglacial records as has been so abundantly done by the well records of Minnesota, Iowa and Ohio. The records in New York state referred to above, while few in number, are still of a character to supply indubitable proof of a Prewisconsin ice invasion in this territory.

During the work of compiling literature relating to the life of postglacial and interglacial deposits, it was observed that little or no attention had been given by New York geologists to the fresh-water life of the ancient lakes of the Champlain substage. The gravels of the Niagara River<sup>4</sup> and certain deposits at Ithaca<sup>5</sup> appear to be the only localities from which life has been definitely reported. Many years ago Hall<sup>6</sup> reported *Unios* and wood from the ridge bordering the south side of Lake Ontario, which marks the shore of the glacial Lake Iroquois. A careful study of this old beach and especially of bays or lagoons behind the beach proper will surely produce results similar to those obtained by Professor Coleman at Toronto.<sup>7</sup>

CHICAGO ACADEMY OF SCIENCES

THE PRODUCTION IN KITTENS INOCULATED WITH  
ENTAMBEA TETRAGENA OF PATHOLOGICAL  
FORMS IDENTICAL WITH ENTAMBEA  
HISTOLYTICA

TO THE EDITOR OF SCIENCE: Schaudinn stated that the reproduction of *E. histolytica* by sporulation "occurs after a period of lively increase when the conditions of life have deteriorated. In dysentery this is simultaneous with the commencement of healing."

I have been able recently by the rectal inoculation of a succession of kittens with trophozoites of *E. tetragena* to observe during a "period of lively increase" the adolescent trophozoite gradually become reduced in size and to note the production of chromidia in

large amount in every individual. This appeared first in the third remove as fine particles in the cytoplasm. In the fourth remove, collections of large particles were seen. The nucleus took on the characters of *E. tetragena*, i. e., prominent karyosome, and at the time of death of the last set of kittens in the fourth remove, typical *tetragena* cysts were seen, but associated with them were forms in which bizarre appearances identical with those figured by Hartmann from Schaudinn's *histolytica* preparations were seen. These are certainly manifestations of pathological cell changes, and represent dislocations of the nucleus, karyorrhexis, karyolysis and extrusion of the nucleus. Many so-called buds were seen, a number of which had become detached from the parent body after the extrusion of chromidia. This budding process seems to be analogous to certain pathological changes in the cytoplasm of mononuclear metazoan cells, for example, in lymphocytes and plasma cells.

The production of budding and other pathological forms identical with the descriptions and drawings of *E. histolytica*, but produced in kittens in a senile precysting race of *E. tetragena* associated with typical *tetragena* cysts indicates almost certainly that *E. histolytica* is a spurious species, having been described by Schaudinn and Craig from senile races of *E. tetragena*.

S. T. DARLING

ANCON HOSPITAL

INDOOR HUMIDITY

TO THE EDITOR OF SCIENCE: In view of the present-day discussion of the subject of indoor humidity some experiments recently carried out by the writer may be of interest to those who, like himself, have been bothered by the bugbear of the "70 per cent." which seems to be the optimum value according to most authorities.

Inside the casing of the hot-air furnace, and right on the dome or hottest part of the firebox, was placed a cast-iron pan with bottom shaped to fit closely. By a simple automatic device connected with the plumbing this was kept full of water, which was found

<sup>4</sup>Letson, *Bull. Buf. Soc.*, N. S., VII, pp. 238-252, 1901.

<sup>5</sup>Tarr, *Journ. of Geol.*, XII, p. 79.

<sup>6</sup>"Geology of New York," Part IV.

<sup>7</sup>*Bull. Geol. Soc. Amer.*, XIV, pp. 347-368.

to boil vigorously in all but the mildest winter weather. When this was supplemented by a crescent-shaped pan on the "radiator" (also inside the casing) the evaporation reached twenty-five or more gallons a day—this in a house of perhaps 20,000 cubic feet capacity.

A number of observations of the relative humidity were made with a sling psychrometer in both mild and severe weather. The effect of this considerable evaporation was to raise the humidity perhaps 15 per cent. above the 25 per cent. or 30 per cent. which is its winter value in most houses in this climate. When the value exceeded 40 per cent., however, very annoying condensation effects were noticeable; even the double windows were drenched with water, while, with zero weather outside, the baseboards and furniture of bedrooms which had been cold during the night were wet. At 50 per cent. the condensation became unbearable, even the walls—although built with double air space—being wet. With the humidity at 40 per cent., however—and it seldom exceeded this value with the above mentioned evaporation—no bad effects were noticeable, while it has certainly added very materially to the comfort of indoor living and possibly contributed in securing immunity from colds.

In conclusion it seems to the writer that considerable effort is required to raise the humidity even a few per cent., but that this effort is nevertheless well worth while; also that 40 per cent. is as high a humidity as can be obtained in this climate in winter without annoying condensation effects, even in a house with double walls and double windows, while 70 per cent. would mean the atmosphere of a steam laundry.

MADISON, WIS.

#### SCIENTIFIC BOOKS

*Le problème physiologique du Sommeil.* By HENRI PIÉRON. Paris, Masson et Cie. 1913. Pp. xv + 520, six figures in text.

This volume makes a notable contribution to the large literature bearing upon the nature

and cause of sleep. That the subject is treated in a comprehensive manner is indicated by the headings of the six parts into which the book is divided, namely, the biology of sleep, under which is included a discussion of related conditions in plants and animals; the physiological phenomena characteristic of sleep, the treatment here being limited to the characteristic sleep in man and the mammalia; states analogous to sleep, including such conditions as coma, narcosis, the action of hypnotics, hypnotic and electrical sleep and hibernation; experimental observations upon the factors of sleep; theories of sleep, and lastly a summary of the present state of the problem together with an outline of his own views upon the subject. The bibliographical and critical part of the book seems to be complete and well done. The author quotes a very extensive literature, and, so far as the reviewer can determine from his own knowledge of the subject, the material referred to has been treated with great fairness to the authors concerned. In fact the impartiality and completeness shown in the presentation of the numerous facts and theories ought to make the book an especially valuable source of information for all who are interested in the subject.

Outside this feature interest attaches chiefly to the experimental contributions made by the author and to the theory which he is led to adopt. His own work, done in collaboration with Legendre, consisted mainly of a study of the toxins produced in dogs kept from sleep during periods varying from 30 to 500 hours. In these animals he obtained evidence of the production of a hypnotoxine which he was able to detect in the blood, brain and cerebrospinal liquid. Incomplete efforts made to isolate this body indicated that it is not dialysable, that it is destroyed by heating to 65° C. and that it is precipitable by alcohol and can be redissolved in water. In the animals subjected to insomnia histological examination demonstrated that there was a distinct degenerative change in the cortex of the prefrontal region. The cells were diminished in

size, the nuclei showed displacement and as regards the Nissl granules there was a condition of chromatolysis or achromatosis more or less complete. When the serum or cerebrospinal liquid from one of these animals was injected into the fourth ventricle of a normal dog this latter animal in a short time gave evidence of somnolence, more or less marked, and upon histological examination showed in the cerebral cortex degenerative changes of the same character as those described for the animal suffering from insomnia. On the basis of these and similar observations the author believes that he has demonstrated the formation during the waking condition of a toxin which may be supposed to have a direct effect in the production of natural sleep. As it accumulates it provokes a condition of fatigue or diminished irritability in the sensory-motor apparatus of the central nervous system, which under the usual conditions may pass into normal sleep. In cases of prolonged insomnia the greater accumulation of the toxine may lead to the production of distinct lesions in the cortical cells and finally to death. When the author comes to apply this idea to an explanation of the mechanism of the daily sleep he encounters a number of theoretical objections which are enumerated and discussed with commendable frankness. The fact that seems to him to be the most difficult to harmonize with his theory is the abruptness with which sleep may appear and disappear. On his view of a gradual intoxication of the nerve cells he admits that there should be a progressive development of somnolence as the toxine gradually depresses the activity of the nerve cells. In view of this difficulty he feels obliged to call upon a secondary hypothesis, suggested by the general views of Brown-Séquard, according to which the hypnotoxine under usual conditions does not paralyze or inhibit the cortical cells directly, but exerts its action indirectly by putting into play an inhibitory nervous mechanism of unknown nature which suspends reflexly the activity of the cells. The reader who follows the author's presentation of the positive results of

his experiments, with an increasing conviction that here at last has been discovered a definite factor destined to throw light upon the causation of this mysterious daily rhythm, is conscious of a distinct feeling of disappointment when he is asked to accept this unattractive hypothesis of an intermediary inhibitory apparatus. One can only conclude that the author has made another addition to the long list of unsatisfactory theories of sleep. However, we must feel grateful to M. Piéron for an apparently very reliable presentation of the difficult literature of the subject, and for the experimental results which indicate that during insomnia a definite toxic material is formed in the body. It is to be hoped that his findings in regard to this hypnotoxine will be corroborated and extended by other observers, although it must be confessed that the experimental procedure involved in the production of long-continued insomnia is of such a character that few investigators are likely to be attracted to the work.

W. H. HOWELL

*The Mosquitoes of North and Central America and the West Indies.* By LELAND O. HOWARD, HARRISON G. DYAR and FREDERICK KNAB. Volumes 1 and 2. Washington, D. C., Carnegie Institution. 1912. Published January and February, 1913.

Nearly thirty years ago I heard Cobbold, the well-known authority on parasitism, lecture on *Filaria sanguinis-hominis* and its relation to the mosquito. It was a good lecture, and created a profound impression; but we who discussed the marvel at that time little imagined what still remained hidden behind the curtain, the merest corner of which had been lifted. In those days the Culicidae, whether regarded from the medical or entomological point of view, were supposed to be relatively unimportant. To-day it seems astonishing that we could have been so ignorant, and yet all the work that has been done is very far from exhausting the subject. In April, 1902, Dr. L. O. Howard applied to the Carnegie Institution of Washington for a grant "which should enable the preparation

of a monograph to include all possible information concerning all mosquitoes" of North and Central America and the West Indies. It was at first expected that the work could be completed in three years, and the grants made covered that period. At the end of that time, however, the work was considered still too imperfect to publish, and was continued for several years more with funds derived from other sources. We now have before us only part of the work, namely, the volume covering the subject in a general way, with a discussion of its medical aspects, and the volume of plates. The descriptions of the genera and species, with detailed information as to distribution and other matters, will follow at some later date.

To those who are not specialists in entomological taxonomy, the first volume is of course by far the most interesting and important, though the later parts will contain a larger proportion of original matter, and will bring out most clearly the great advances made in our knowledge of the Culicidæ by the authors. One's first impression on taking up the first volume is that of wonder at the space needed (520 pages) for what is, after all, a general introductory discussion. On perusing the separate chapters, we are inclined to change our attitude, and marvel rather that it has been possible to treat of so many important topics in a single volume. Then again, our first naïve astonishment that so much is known about mosquitoes gives way to a profound sense of the great amount there is yet to learn. The monograph is "complete" in the sense that it apparently includes all the important available information bearing upon its topic, but almost every chapter suggests to the mind of the reader numerous possible interesting researches. Thus the book is one of those live ones which will, as the result of one of its merits, soon become more or less out of date.

Modern science demands the publication of works which are too expensive and of too broad a scope to be, except in rare instances, prepared by a single man. Thus the mosquito monograph, due to three authors, and con-

taining in addition extensive quotations from many others, stands as a type of the scientific monographs (if the word may still be allowed!) of the future. Prepared by men who are thoroughly familiar with the subject, having contributed many more new observations than any others in this country, it is very far from being a mere compilation; yet there has been no hesitation in compiling from the best sources in every case, with full credit given and usually the exact words of the writers cited. All this involves a certain sacrifice of ostensible originality, but it is much to be preferred to the method of many writers of general works, who, on the plea of uniformity of treatment, undertake to discuss subjects they do not understand, and in using other writings make all sorts of blunders. In the present instance the authors distinctly state that they are "entomologists and not physicians or medical investigators," and so the chapters dealing with medical matters "are not the result of original investigation," although it is well known that the senior author is an expert on medical entomology.

Following the Introduction is a chapter headed Early Accounts of Mosquitoes, which includes among other things a long and interesting quotation from Humboldt. The structure of the mosquito is discussed in about 80 pages, including the immature stages as well as the adult. Standard descriptions are quoted from Child, Dimmock, Kellogg, Nuttall and Shipley, Snodgrass, J. W. W. Stephens, Christophers, Raschke, Hurst, Eysell and others; but the original observations of the authors are more interesting than any of these, since they alone know enough species to give a good *comparative* account. So much that is significant appears from the comparative study of the different organs of various Culicidæ, that there is evidently a splendid field for further research along the same lines, especially in reference to the internal organs. When the taxonomic volume appears, it will no doubt be possible for workers in any part of the country to readily and accurately determine the species they may use in such studies.

The habits of mosquitoes, adults and young, are treated in 50 pages, followed by a detailed account of their natural enemies. This last topic is evidently capable of great extension, and it is evident that any intelligent amateur can readily add to what is known by observations in his own locality. The relation of mosquitoes to man occupies about 260 pages, covering both theoretical and practical aspects. The very clear and well written, but not in the least sensational, accounts of the discovery of the connection between mosquitoes and malaria and yellow fever ought to be reprinted and distributed broadcast over the country. Some bulletins of the Department of Agriculture give useful practical information about mosquitoes and disease, and there are various other more or less accessible publications dealing with these matters; but would it not be a good thing if the plain, unvarnished, historical account of the work of Manson, Ross, Grassi, Finlay, Reed, Carroll and Lazear (and we should like to add portraits of these men) could be sent, in the form of a pamphlet, to every school in North America? We offer the suggestion to Mr. Carnegie. To this account might be added the words of the authors, who after describing brilliant anti-malarial work in foreign countries, are obliged to say: "In the United States, it is sad to relate, almost nothing has been done in the way of an active campaign against malaria alone, even in restricted localities. It is true that extensive work has been done against mosquitoes, but in the most of these cases the incentive does not seem to have been to better the health of the people or to stamp out malaria." The volume ends with a bibliography and a very complete index.

The second volume contains 150 beautiful plates, illustrating the structural characters of the eggs, larvæ, pupæ and adults. In a work otherwise characterized by such conscientious crediting of all assistance, it is surprising to see no reference to the artist or artists of the plates; doubtless this information will be given in the next volume.<sup>1</sup> We

<sup>1</sup> I have since learned that the drawings of whole larvæ and the detail drawings of larvæ (plates 86-

note that in the names of species, no attempt is made to alter the terminations of adjectival specific names to make them agree in gender with the names of the genera to which they are referred.

T. D. A. COCKERELL

UNIVERSITY OF COLORADO

*Trees in Winter: their Study, Planting, Care and Identification.* By ALBERT FRANCIS BLAKESLEE, Ph.D., Professor of Botany and Director of Summer School, Connecticut Agricultural College, and CHESTER DEACON JARVIS, Ph.D., Horticulturist, Storrs Experiment Station. Illustrated Octavo, 446 pp. New York, The Macmillan Company. 1913.

About a year ago the writer of this review had the pleasure of making a short notice<sup>1</sup> of Bulletin 69 of the Storrs Agricultural Experiment Station, entitled "New England Trees in Winter" by the authors of the work now under consideration. Then we said "We do not recall any better treatment of our trees than is to be found in this publication." Further use of the bulletin confirms the favorable impression made on its first appearance. We have now a very considerable enlargement and revision of the bulletin in the form of the stout volume whose name appears at the head of this review. In revising the earlier publication the authors have introduced chapters on the structure, life and growth of trees, their propagation, tree planting in the country and the city, how to plant, care, common injuries, control of parasites, insecticides, etc. In these chapters the authors have managed to condense a great deal of valuable information for the general reader, and especially for the owner of a piece of ground on which trees are now growing, or on which the owner wishes to plant trees. Nor do they present the growing of trees merely from the standpoint of utility, although that is sufficiently empha-

131) are by Mr. Knab, part of the latter inked in by Miss Mary Carmody. The male genitalia are drawn by Miss Carmody; the eggs (plates 146-147) are by Miss E. G. Mitchell. The photograph of *Anopheles* wings is by Mr. H. S. Barber.

<sup>1</sup> SCIENCE, March 22, 1912.

sized. We like the opening sentences in Chapter III., and can not refrain from quoting some of them, as follows:

Every citizen in every country is interested, or should be interested, in good scenery. Of the various elements that constitute good scenery or that go to make up our landscape there are none so ornamental nor so indispensable as trees.

In discussions relating to the conservation of our natural resources, therefore, the element of good scenery should always be considered. Since good forests, good farms and good waterways contribute largely to the landscape, the element of good scenery can not easily be separated from many of the commonly recognized natural resources.

Trees have become so much a part of our civilization that it would seem almost impossible to get along without them. What would our homes, our country roads, our city streets, our parks, and our landscape be without them? We all know that trees are beautiful and even necessary in such places, but we can not fully appreciate their value till we have seen the desert.

The value of trees from the economic or commercial standpoint is well understood and can be estimated on the basis of dollars and cents. Their esthetic value and their value from the standpoint of health is not so generally appreciated nor is it so amenable to calculation. We hear a great deal these days about surveys—forest surveys, agricultural surveys and the like. A survey in this sense means an inventory or a stock-taking. It would be interesting to make a survey based upon the landscape wealth of any section or of the whole country. It would be interesting also to compare in such a survey the relative value of the various elements of the landscape. It seems safe to predict that in most sections trees would be credited with a very large proportion of the total wealth.

And again in Chapter IV., we find these suggestive sentences:

When we think of the open country we are reminded of the cool and shady roads, although some country roads are not so alluring as they ought to be. The thought is comforting. On the other hand, when we think of conditions in the city, the hot and dazzling pavements present themselves vividly to our memory. The thought is anything but comforting. Blessed is the city that is well supplied with trees.

The attractiveness of a city depends largely upon

its trees. A city without trees can not be attractive, and the more trees within the city limits, the more attractive is the city likely to be.

Passing to the systematic part of the book there is first a general chapter on the identification of trees, with such explanation of terms as will render this work easier for the beginner. Then follow various keys, as (1) a key to genera, (2) keys to the conifers, (3) keys to the various kinds of deciduous trees. These keys refer to full-page descriptions and discussions of the particular species, and on the opposite page is a full-page plate of characteristic illustrations made by "half-tone" process from carefully selected photographs. These descriptions cover habit, bark, twigs, leaves (in evergreens only), buds, fruit, comparisons with other species, distribution, and wood characters. Preceding the descriptive matter is an English name, followed by the scientific name, very properly in a book like this, accompanied by the "authority" for the species. A convenient glossary and a well arranged index complete this useful book. The binders have enclosed the text in a pretty and appropriate cover in keeping with its title.

CHARLES E. BESSEY

THE UNIVERSITY OF NEBRASKA

*Science and the Human Mind, a Critical and Historical Account of the Development of Natural Knowledge.* By WILLIAM CECIL DAMPIER WHETHAM, M.A., F.R.S., Fellow and Tutor of Trinity College, Cambridge, and CATHERINE DURNING WHETHAM, his wife. New York, Longmans, Green, and Co. 1912. Pp. xii + 304. Price, \$1.60 net.

This work consists of an Introduction, and of six chapters on Science in the Ancient World, the Medieval Mind, the Renaissance and its Achievement, the Physics of the Nineteenth Century, the Coming of Evolution, and the Last Stage; of a good bibliography (pp. 287-296), and of a full index. The authors are already known favorably to scientific men by their "A Treatise on the Theory of Solution" and "The Theory of Experimental Electricity"; to the general public by their admirable "The Recent Advance of Physical

Science"; and to students of society by several publications on heredity and eugenics. In other words, they have proven their right to the present undertaking by substantial contributions to at least two distinct fields of research.

It is obvious, of course, that a field so vast can not be covered satisfactorily in a single volume of moderate size. Accepting this limitation as inevitable, and setting aside criticisms which, unmindful of it, one might pass readily, it may be said at once that the effort is remarkably successful. Indeed, I am unacquainted with a better book, particularly in the matter of unexpected suggestiveness (towards the close notably), of equal or briefer compass. I would commend the spirited, sometimes eloquent picture of the medieval mind (pp. 64 f.), the lucid account of Newton (pp. 128 f.), the absorbing tale of the rise of electrical science (pp. 181 f.), the generous tribute to Darwin (pp. 209 f.), and the last chapter (pp. 233 f.), which is, in itself, enough to justify the book. It is a pleasure to meet devotees of "natural knowledge" who not only can write, but evince sane appreciation of humanistic knowledge.

The blots are few. Here and there, especially in the Introduction and on the last page, the authors permit themselves to be betrayed into what I take the liberty to call silly remarks about philosophy and metaphysics. Plainly, their *Wissenschaft* knows not these subjects as *Wissenschaft*. This is the more striking that, in other contexts, they make most ample amends. I mention this, because it punctuates the contrast between themselves and Dr. Th. Merz, with whom they are likely to be compared. They may feel his catholicity, they do not always observe it.

The race-theory, a result of their sociological inquiries, which Mr. and Mrs. Whetham apply to their subject, is one of the fascinating features of the book. "Natural knowledge" has been formulated and developed by the races of northwestern Europe. "It is possible that danger to science, as to society, lies ahead. . . . The dominance of the universal proletariat, which some dread and others ac-

claim—a proletariat not dissimilar in race to the southern rulers of the Roman Church—may threaten in the future the freedom of enquiry, the fearless exercise of reason, the full development of personality, that form the life-blood of the northern race and its scientific achievement. . . . If the same race once more gains ascendancy in northern lands, as, by the differential birth-rate and the downward shift of political power, it seems destined to do, it is difficult to believe that scientific results which threaten its prejudices or are not in accord with its ideals will be respected" (pp. 279–80). Darwin was a conspicuous product of the Anglo-Danish and East Anglian folk, who have done most for the progress of science. And so, Mr. Whetham is able to construct a great brief for his own, the East Anglian, university. Nevertheless, I do not see why he should have omitted Macquorn Rankine in reference to the foundation of thermodynamics (p. 179). Nor does his theory, of the mysticism of the northern race, supply the reason why Kelvin "is said to have begun his lectures on physics with the Collect for the day" (p. 158). As a pupil, I may say that Kelvin did so, but because it was the universal custom at Glasgow to open the morning classes with prayer. Nevertheless, I accept the theory, as indeed I must—my paternal ancestors for generations are East Anglians! And yet, I am in doubt; for I still traffic in "speculative philosophy, tossed about by every wind of doctrine" (p. 7). But, it were too hard a test to ask an author to prove his theory on the *corpus vile* of a reviewer of whom he never heard tell. So, once more, I say the book is thoroughly worth while.

ANN ARBOR

#### NOTES ON ENTOMOLOGY

THE eleventh volume of the Hampson catalogue of moths has been issued by the British Museum.<sup>1</sup> It deals with four groups—Ente-

<sup>1</sup>"Catalogue of the Lepidoptera Phalaenæ in the British Museum," Vol. XI, pp. 689, text figs. 175, pls. CLXXIV–CXCL, 1912.

lianæ, Stictopterinae, Sarrothripinae, and Acontianæ, which include nearly 1,000 species arranged in about 150 genera. They are mostly from tropical countries.

ONE of the most interesting series of books is that on the fauna of India. A recent volume by Canon Fowler on the beetles is especially attractive because of the general account of the Coleoptera.<sup>2</sup> There is a discussion of the several recent classifications of Coleoptera, the author using, although hardly accepting, three principal divisions, Adepaga, Polycerata and Lamellicornia. The essential characters are given for each family, 103 of which are recognized by Fowler, and a short account of their habits, larvæ, distribution and peculiar forms. A glossary of technical terms used in Coleoptera is also included. In the main part of the work the Indian tiger beetles are fully described and many illustrated in text figures. The part on the Pausidæ includes a summary of their habits, and the little known about their larvæ. The Rhysodidæ and Cupedidæ are also treated in this volume, each with only a few species.

OF all the peculiar termitophilous insects the Histerid beetle recently described by Dr. E. Mjöberg will easily rank as the most remarkable.<sup>3</sup> It is a native, of course, of Australia. There are two tufts or pencils of long, curved hairs arising from each side of the base of the elytra. The termites gather a secretion from these hairs, but it is not known whether the secretion comes from the hairs. The insect is named *Eucurtia paradoxa*.

THE value of minute structures in classification is well illustrated by an article on the classification of the bed bugs by Dr. K. Jordan and N. C. Rothschild.<sup>4</sup> They divide the

family into three subfamilies on the nature of certain bristles, whether serrate on certain portions or not. The Clinocorinae includes *Clinocoris* and *Æciacus*; the Cacodminæ includes *Cacodmus*, *Loxaspis* and *Aphrania*, and the Hæmatosiphoninae the one genus *Hæmatosiphon*.

THE life habits of structurally peculiar insects are apt to be unusual, and Dr. F. Germer has found this true of the Lymexylonidæ.<sup>5</sup> The adult does not feed, but the larvæ apparently feed on a fungus that grows in their burrows. The author illustrates the peculiar structures of antennæ and palpi in various sensory functions.

DR. A. DÜCKE has published a revision of the South American genera of bees.<sup>6</sup> He gives a bibliography of South American bees since Dalla Torre's catalogue, a synopsis of the sixty-eight genera known from the region, the geographical distribution of each genus, in some cases a list of the described species, and descriptions of a few new forms.

PROFESSOR T. MIYAKE has given the most complete account, so far, of the life history of a Panorpid.<sup>7</sup> The eggs are deposited in clusters of from six to ten in crevices in the soil. The larva of the Japanese species is similar to that of the European and American species already figured. They probably pass through seven molts, the perforations in the spiracles increasing in number with each molt. The larvæ feed on dead insects. There are two broods in a year. The adults were observed to feed on dead insects and the petals of a flower. None have been observed catching living insects.

DRS. J. SCHNABEL and H. Dziedzicki have produced a most important work on the

<sup>2</sup>"The Fauna of British India, including Ceylon and Burma," Coleoptera, I, General Introduction, Cicindelidæ and Pausidæ, 529 pp., 240 figs., London, 1912.

<sup>3</sup>"On a New Termitophilous Genus of the Family Histeridæ," *Ent. Tidskrift*, 1912, p. 121-124, 1 plate.

<sup>4</sup>"Notes on the Clinocoridæ, a Family of Rhynchota, with Descriptions of a New Genus and Species," *Novit. Zool.*, 1912, p. 352-356.

<sup>5</sup>"Untersuchungen über die Bau und Lebensweise der Lymexyloniden," *Zeitschr. wiss. zool.* (1), Bd. 101 (1912), pp. 683-785, 2 pls., 31 text figs.

Anthomyiæ.<sup>8</sup> It is a critical revision of the genera of the family, with especial consideration of the male genital apparatus, and all the plates represent hypopygia or lobes of the fifth ventral segment. The authors consider the family in the sense of Girschner, including most of the Muscidae. In the supplementary part are descriptions of many new species, mostly from Russia.

The progress of entomology in South America is unfortunately slow, and for this reason we welcome each new elementary treatise from that quarter as an encouragement for the local naturalists to collect and study their insects. A new work of this character is by Dr. C. E. Porter on the Myriopods of Chili.<sup>9</sup> He gives an illustrated account of the structure and habits of myriopods, and follows with an annotated list of the 64 species so far described from Chili. Many of the genera are different from those of our country, and several are peculiar to Chili.

THE anatomical part of the 34th (1912) volume of the *Zoologisches Jahrbücher* is more than ordinarily occupied by entomological articles. Mr. Edw. Schoenemund gives a descriptive and biological study of the larvæ of the three large European Perlas,<sup>10</sup> with notes on the anatomy of the respiratory and digestive systems, and the development of the sexual organs.

Mr. S. Surlov has an article on the salivary glands in the head of some Orthoptera, especially *Mantis*<sup>11</sup> and their relation to similar glands in Myriapoda.

Dr. H. Mammen gives a comprehensive study of the comparative morphology of the stigma in various Hemiptera,<sup>12</sup> both in

<sup>8</sup>"Die Anthomyiden," *Abh. Kaiserl. Leop.-Carol., Deutsch. Akad. Naturf.*, XCV. (No. 2), pp. 55-358, 35 pls., 1912.

### SPECIAL ARTICLES

#### PALMESTHETIC BEATS AND DIFFERENCE TONES<sup>1</sup>

IN publishing the results of my experiments on palmesthetic difference sensibility,<sup>2</sup> I did not take up the question whether the discriminations with which we were dealing were of rates of succession of discrete sensations, or of differences in the characters or quasi-characters of continuous sensations. That this question must be raised is of course obvious, since the vibration-rates of the forks I employed (between four and five hundred vibrations per second), are below the fusion limit as reported by Valentin,<sup>3</sup> von Wittich,<sup>4</sup> Schwaner<sup>5</sup> and others. The results of Preyer,<sup>6</sup>

<sup>1</sup>"Statische Sinnesorgane bei den Nepiden," pp. 179-346, 4 pls.

<sup>2</sup>"Vergleichend-anatomische Untersuchungen über den Stechapparat der Ameisen," pp. 347-380, 2 pls.

Lalanne<sup>7</sup> and Mach,<sup>8</sup> giving the fusion limit far below the range I employed, throw doubt on the other results, and make it evident that there is somewhere in the determination a factor which has escaped attention by one group or the other of the experiments, or possibly by both.

The early observations were made with little reckoning of the troublesome psychological problems involved, and with no reference to the possibility which we must at present admit—that vibratory stimuli applied to certain portions of the skin may rouse sensations other than those of pressure, touch, temperature or pain: sensations of vibration, or palmar-esthetic<sup>9</sup> sensations, as they are provisionally designated. The former point we will consider below; the latter is of prime consequence.

If an observer assumes that when a tuning fork (the stem of it or some attachment to a prong) is applied to the skin the sensation aroused will be either that of mere continuous touch or pressure (we may leave out of account pain and temperature, as being easily discriminated from the other), as when the fork at rest (not vibrating, that is) is applied; or else of the discrete series of touches corresponding to the individual periods of the vibration, his observational problem will be comparatively simple. If the fork is perceived as being in vibration, the judgment will be "*discrete pulses*," or "series of discrete tactual sensation"; if the fork feels as if not vibrating, the judgment will be "*fusion*." In other words, the problem of observation is restricted to the question whether or not the fork can be perceived to be in vibration. This, we may reasonably infer, was actually the problem as understood by a number of the experimenters; and consequently the thresholds of fusion they reported were limited simply by the mechanical capacity of the forks (or whatever serial stimu-

lation devices were employed) to produce a sufficiently intense vibratory stimulus.

When we admit the possibility that the vibration of the fork may produce a sensation which is not identical with the simple touch or pressure sensation, the problem becomes entirely different. It is now a question of determining the point (in rapidity of stimulus) at which the sensation enters, or the point at which it becomes a continuous sensation; or possibly we may have to make both determinations. That there are abundant clinical observations which go to show the existence of a palmar-esthetic sensibility not identical with touch or pressure, I pointed out in my first paper.

The forks with which I first worked (in the neighborhood of 440 vibrations per second) were too heavy for their length, and the vibration-feeling consequently feeble and of brief duration. I have since secured some forks which are better adapted to the work, being relatively more slender, and have carried on observations with these. They have prongs approximately  $8 \times 5.5$  mm. in cross section, and 19 cm. long for *c* (128 per sec.) and 13 cm. long for *c'* (256 per sec.). The *c'* forks of the same cross section, 9 cm. long, are less satisfactory. The forks have been fitted (by our mechanic) with tubular brass extensions to the stems, giving a total length from the crotch of 9.5 cm. The end of the extension is solid, with a diameter of 1 cm. Weights with clamp-screws are fitted to slide on the prongs so that the forks may be tuned from the original *c* and *c'* down to the *F* and *f* below, by any required steps.

These forks were prepared primarily for the purpose of determining difference-sensibility in the octaves represented. This work has not been completed, but shows, so far, about the same threshold as was earlier obtained in the middle octave (approximately 10 per cent.). The present report is not concerned with this measure.

We early noticed that beats were palmar-esthetically perceived, and were as distinct and characteristic as auditory beats. With properly tuned forks, we found differential sensa-

<sup>7</sup>Lalanne, "Sur la durée de la sensation tactile," *C. R. de l'acad. des sci.*, LXXXII, 1314.

<sup>8</sup>Mach, E., *Sitzber. d. Wiener Akad.*, LI, 2, 142.

<sup>9</sup>The term was introduced in German, by Rydel and Seiffer in 1903.

tions, corresponding to auditory difference-tones. In arousing these, the two fork stems were firmly pressed together, and the circular end of one stem pressed lightly against the skin of the border of the palm; or the subject's finger tips were pressed lightly against the fork stem.

Fearing lest the phenomenon might be some peculiarity of the action of the physical couple corresponding to the "objective" difference tone, certain auditory experiments were carried out, as follows. A König resonator was tuned to the difference tone of one of the forks; it of course gave no response when the vibrating forks were not in contact, and it still gave no response when the stems were pressed together. Pressing both stems against a block of resonant wood failed to make the resonator respond, although the wood was brought within a few inches of the orifice of the resonator. A single fork tuned to the difference-tone and resonator, pressed against the wood in this way, evoked a loud response from the resonator, even when the fork was vibrating feebly.

It occurred to me that the point (in the scale of rapidity) at which the beats passed into a differential sensation might give a measure of the lower limit of palmesthetic sensibility, and that in any case the determination of this point was important. Here the difficulties were encountered.

As only an approximate determination was desirable at this juncture, one of the *c'* forks was scaled in the steps *b*, *a*, *g♯*, *g*, *f♯* and *f*, certified forks being at hand for these rates, giving differences with the other *c'* fork of 16, 33 +, 42 +, 56, 64, 78 + and 85 + double vibrations.

In my own case, the determination is fairly certain. The beats are distinctly perceptible down to *c'-g* (64). At *c'-f♯* (78 +) this discreteness begins to pass into a sensation comparable to that of another fork (*i. e.*, a continuous sensation), and at *c'-f* (85 +) this new sensation becomes unmistakable and definite, the beats entirely disappearing.

With still greater difference, the differen-

tial sensation persists, becoming less and less intense, as is the case with the sensations aroused by single forks of increasingly higher pitch.

In the first day's work with W., a graduate student, the results were exactly the same as those obtained from myself and were invariable. A month later his results were radically different. He still observed the differential sensation as like that from a low fork, but claimed that it was a matter of discrete pulses, differing from the beats of smaller differences only in rapidity. In fact, he now claimed that the single-fork stimuli, even from the 512 fork, gave series of discrete sensations, and further claimed that the auditory stimulus from the same fork produced the same sort of discrete sensations, corresponding to the air pulses. It should be said that W. is unmusical, but is a good observer.

My own observations fit in quite well with those of W., as regards the palmesthetic sensations, although the auditory sensations (beyond 40 vibrations per second) are always sensibly continuous. With best attention, the palmesthetic sensation (beyond 85 per second), is as continuous as the auditory, but nevertheless at certain other times it seems to be a discontinuous series. In my observations, however, there is a clear indication of the reason for this discrepancy. In one case I am attending to the sensation as it is; and in the other case to the fork thought of as an oscillating body—to the representation of visual or muscular sort—rather than to the actual presented sensation. Such training as my palmesthetic sensibility has received during the greater part of my life has probably been in the way of interpreting the sensations in terms of the vibrations represented as movements of some body; hence, even when I should be attending to the sensation I still incline to attend to the meaning instead. A large number of individuals undoubtedly tend to treat vibration in this way.

In attending to sounds, the interpretative tendency is not so strong, as the conditions are not so conducive to training in this direction. The special significance of sounds as

indicating oscillatory movement is more remote, and more easily detached from the sensation. This detachment was difficult for W., in the case of the tuning fork, because it was for him principally an instrument for the inscribing of curves for time-measurement: the sound of the fork signified its motion in space, and the intensity signified the amplitude of the sinusoidal line it could trace. This observation was made by W. and reported in practically the words I have used.

The results of observations made by several other subjects give about the same threshold as my own observations. One graduate student, J., perceived no beats at  $c'-g\sharp$  (56), obtaining perfect fusion at that point, although in auditory experiments the fusion was not complete until 64 was reached. This subject at no time had tendency to confuse the sensation and the motion. He is quite musical.

Another graduate student, B., reported that he was constantly troubled by the "visualization" of the tuning-fork curve. He perceived clearly the discreteness of the beats up to  $c'-f\sharp$  (78+), but beyond that point was unable to decide whether the sensation was or was not continuous.

D., an undergraduate student with previous training in palmesthetic work, and in discrimination of rates and in certain other sorts of psychological observation, obtained clear fusion at  $c'-f\sharp$  (78½) and undoubted discreteness at  $c'-a$  (42½). Between these points, there was doubt, and variation in his judgments.

It should be noted that the differential sensation (above about 80) is perceived as exactly like that due to the addition of a third fork, even by subjects who judge it to be a matter of discrete phases. The problem is, therefore, not to decide as to the character of the differential sensation merely, but concerns any vibration of the same rate.

The differential, when faint, may be made perceptible in a way quite similar to that in which the auditory differential is brought out, namely, by stimulating with the lower of the two forks alone for a moment, and then adding the higher; the resultant drop in the pitch

of the clang is paralleled by the corresponding change in the felt vibration.

In the tests described herein, the forks were not audible, they being weakly excited, and used at a sufficient distance from the subject's head—at arm's length. In fact, they were scarcely audible when brought up to half the distance from the head.

After making these observations, I am compelled to view with suspicion the results of any simple observations on the threshold of discreteness and fusion in the palmesthetic or haptic realms (and, indeed, in the auditory realm also). I include my own observations in this suspicion, along with others, for while I may say that my observations have been very careful, they can not do more than establish a presumption. Mere observation ("introspection" in the sense of the word now happily becoming obsolete) is productive of no certain results; the measurements I have been describing are excellent vehicles for the demonstration of the fact, and I strongly recommend them to any one who is inclined to rely on the results of simple observation. These observations are not experimental in the proper sense of the word; but fortunately it is possible to apply experimental methods to the problem upon which they bear.

The palmesthetic difference sensation can not be wholly without significance for the theory of auditory perception. Although I have a bias against the "telephone" theory, I must admit that the perception of a difference in vibration rate by dermal or subdermal nerves, and the detection of a differential rate by these same nerves, seems to support strongly the assumption that differences in pitch of sound are not essentially connected with differences in peripheral nervous elements, but that the same cochlear nerve terminations may mediate different pitches, and the same pitch be mediated by different terminations.

KNIGHT DUNLAP

#### ECHINODERM HYBRIDIZATION

It is my purpose to call attention in this note to certain facts, the consideration of which may do something toward bringing

order out of the apparent confusion in which the subject of Echinoderm hybridization is involved.

I may preface my remarks by saying that actually no confusion exists. The apparent confusion is the result of too narrow and restricted a view of the facts, but the student of genetics whose attention has not been called in detail to the matter has no means of realizing that this is true.

In at least two published papers I have made in substance this statement:

It is well known that an apparent confusion exists among observations on hybrid Echinoid larvæ, as to whether plutei of a maternal type, a paternal type or of mixed form are derived from certain crosses. Different results have been obtained by different investigators and by the same investigators working in different regions or in the same region in different seasons.

This statement was made after the consideration of the work of Boveri, Driesch, Morgan, Seeliger, Vernon, Doncaster, Herbst, Steinbrück and others, in connection with my own observations, extending at that time over a period of five years, which were based upon some fifteen successful crosses.

If further proof of the truth of the quoted statement be needed we have it in the results of Hagedoorn, who wrote in 1909 on the "Purely Motherly Character of the Hybrids produced from the Eggs of *Strongylocentrotus*," and of Loeb, King and Moore, who in 1910, after working on the same type of material, in the same region, reached the conclusion that the hybrids show neither a preponderance of paternal nor of maternal influence.

Again, Shearer, De Morgan and Fuchs in 1911 published a "Preliminary Notice on the Experimental Hybridization of Echinoids," based upon three years' study of three species of *Echinus*, in which they state the conclusion "that the inheritance of the late larval characters was invariably maternal." In 1912, after another year's work on the same forms they published in the *Quarterly Journal of Microscopical Science*, Vol. 58,

To our surprise, however, the behaviour of some of the hybrids has differed greatly this season

from that of previous years. In late larval life some of the hybrid crosses have shown as strictly a paternal inheritance as in previous years they have shown a maternal one.

It is perfectly evident then that the observations of these later students confirm the truth which I have been trying to establish from my own work, as well as urging that it had already been established by earlier investigators. I emphasize again then the fact that no actual confusion exists. It has been established again and again that under some conditions we may obtain larvæ of a maternal type with respect to certain characters, under other conditions larvæ of a paternal type and under still other conditions larvæ of a blended type. This is established. We should accept the fact.

*The real problem in Echinoderm hybridization is the determination of the conditions under which these various types appear.*

Another idea to which I wish to call attention is embodied in a statement in the summary of the Shearer, De Morgan and Fuchs 1911 paper:

As the result of extensive investigation of the early larval history of our various crosses, we have come to the conclusion that these are too variable to afford any definite evidence of parental influence and especially is this true with regard to the skeleton, heretofore considered the chief index of inheritance.

This generalization from a few crosses should not be applied to all. I am very willing to admit the statement for the Shearer, De Morgan and Fuchs crosses. I can not admit it for some of my own.

In my investigation of the variation of Echinoid plutei I made a prolonged study of the skeleton of *Toxopneustes* plutei. I know what the variations in the skeleton under laboratory conditions are, and I determined these variations before drawing my final conclusions as to the character of the skeleton in hybrids. When the extent and nature of the variations in the skeleton have been determined it may well serve as one of the indices of inheritance in crosses.

Further than this, in proper material, pa-

ternal influence may be demonstrated in stages even younger than the pluteus. I am now able to show definite and clear-cut evidence of such influence in the early gastrula stage. This evidence will soon be published in detail, so I shall give it here only in summary.

The material from which this proof is gained was obtained in February, 1911, while I was working at the temporary station established by the department of marine biology of the Carnegie Institution in Montego Bay, Jamaica, British West Indies. The research involved the investigation of the normal development of *Cidaris tribuloides* and of the hybrids obtained by crosses between *Cidaris*, *Hipponoe* and *Toxopneustes*.

In its normal development *Cidaris* is unlike the modern Echinoids in that the primary mesenchyme is formed late, the cells arising 23-26 hours after the fertilization of the egg, from the inner end of the archenteron, which has pushed, by this time, well into the blastocœle. No mesenchyme cells appear during the blastula stage. In *Toxopneustes*, as is well known, the primary mesenchyme cells arise about 8 hours after the fertilization of the egg, at the posterior pole of the blastula and have passed into the blastocœle before the beginning of the invagination of the archenteron. A similar condition holds for *Hipponoe*.

In the *Cidaris* ♀ × *Toxopneustes* ♂ and the *Cidaris* ♀ × *Hipponoe* ♂ crosses, gastrulation begins in about 23 hours after fertilization, as in the straight fertilized *Cidaris* eggs, the process not being noticeably hastened by the use of the foreign sperm. The primary mesenchyme appears about one hour later, the cells arising around the base of the then very short archenteron, at the region of the lips of the blastopore.

The influence of the foreign sperm is thus clearly shown in the changed site of mesenchyme formation. Furthermore, it appears ontogenetically earlier in the hybrids than in the normal *Cidaris* larvæ.

In calling attention to these matters I do not wish to disparage in any degree the work being done by Shearer, De Morgan and Fuchs and the other British zoologists who have re-

cently begun work in this field. Their work on the later stages is admirable. I do wish to plead against the acceptance of negative evidence as the basis for a positive generalization concerning the early stages in Echinoid crosses. Well-chosen material may give positive evidence.

DAVID H. TENNENT

#### SOCIETIES AND ACADEMIES

##### THE ACADEMY OF SCIENCE OF ST. LOUIS

At the regular meeting of the Academy on February 3 and 17, the following papers were read:

Dr. C. H. Turner: "Apparent Reversal of the Light Responses of the Common Roach."

Dr. LeRoy McMaster: "The Preparation and Properties of the Ammonium Salts of Some Organic Acids."

Dr. Leo Loeb: "Some Biological Aspects of Tumor Investigation."

Dr. Turner discussed a series of experiments conducted with the common roach (*Periplaneta orientalis*) for the purpose of seeing if a negatively phototropic animal could be trained to refuse to enter a specific dark place; and, if that proved possible, for the additional purpose of obtaining an experimental analysis of the behavior.

The electrical punishment method, devised by Professor Yerkes in his study of the dancing mouse, was used.

The speaker stated that he had trained roaches of both sexes and different ages to avoid a specific dark place, and insisted it was equally as logical to interpret his results by concluding that the roach, by means of associated memory, had learned to avoid a specific dark place, as to term its behavior a reversal of negative phototropism.

Professor McMaster described a method of preparing the neutral ammonium salts of monobasic and dibasic organic acids, by dissolving the acids in absolute alcohol or ether and passing dry ammonium gas into the solution. There easily resulted the neutral ammonium salts of succinic, tartaric, ortho- and meta-phthalic, propionic, isobutyric and benzoic acids. Malonic, malic and cinnamic acid salts resulted with difficulty. Analyses showed the compounds to be neutral.<sup>2</sup>

<sup>1</sup> *Biological Bulletin*, Vol. XXIII., 1912, pp. 371-386.

<sup>2</sup> This paper will appear in the April number of the *American Chemical Journal*.

Dr. Loeb pointed out that Weismann's statement that the somatic cells of Metozoa are mortal is not warranted by the facts, the evidence leading merely to the conclusion that somatic cells can usually not reproduce the whole organism. In 1901 Dr. Loeb himself first announced that facts established through experimental tumor investigation made it very probable that tumor cells are potentially immortal, as much so as Protozoa and germ cells, and a few years later he concluded further that, inasmuch as tumor cells are merely ordinary somatic cells living under special conditions, the proof had been supplied, as far as that can be done, that ordinary somatic cells are potentially immortal. He also pointed out that this conclusion could be still further confirmed by serial transplantations of ordinary tissues in animals of various ages. He began such experiments a number of years ago and is continuing this work now under more favorable conditions.

Experimental tumor investigation has furthermore demonstrated that many somatic cells have a potential power to proliferate which appeared almost unthinkable until recent years, one single epithelial or connective tissue cell being potentially able to produce masses of cells which surpass many times the number of cells composing a whole animal of the same species.

Investigations by M. S. Fleisher, in Dr. Loeb's laboratory, fail to show the definite rhythmic changes attributed to tumors by Bashford and Calkins, and Dr. Loeb thinks that if they exist in the case of other somatic tissues, they are not primary attributes of these tissues, but due to secondary mechanisms.

Professor Nipher stated to the Academy that he had recently obtained results confirming his previous conclusion that the strength of a steel magnet depends upon its electric potential.

#### THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

THE 467th regular meeting of the Anthropological Society of Washington was held in room 43 of the new building of the National Museum at 4:30 P.M., March 18, 1913, the president, Mr. Stetson, in the chair. Dr. John R. Swanton read a paper on "The Creek Confederacy."

After explaining the geographical and linguistic positions of the tribes of the Creek confederacy

with the assistance of a map, Dr. Swanton traced the evolution of the confederation from a small nucleus of tribes speaking the Muskogee language to a large association, comprising a number of Hitchiti speaking people, the Alabama, Koasati, some of the Apalachee and Yamasi, part of the Natchez, the Yuchi, and, for a time, some of the Shawnee. He showed that this association was facilitated through the institution of a dual division of towns into white or peace towns and red or war towns, the towns of each division, or "fire," considering each other friends or allies, and having opposing but not warlike relations with the towns of the other "fire." It thus happened that when an outside town or tribe came to be accepted as a "friend" of one of the white or red towns in the confederacy its position with reference to all of the other white and red towns was thus established and it entered into the confederate scheme. The communication of other common features to the new towns also took place, although more slowly. Such features were the "green corn dance" or busk, or perhaps rather the Muskogee form of it, participation in common although irregular councils, and the adoption of Muskogee as the standard language of intercommunication. The actual discontinuance of the proper languages of the various members of the confederacy was, fortunately for the ethnologist, much slower, several of them having persisted down to the present day. Through the progressive adoption of smaller tribes and the practical destruction of some in warfare, a process accelerated by white contact, the Creek confederacy came to be almost the sole representative of eastern Muskogean culture, and even influenced the culture of the Chickasaw to a marked degree. The great Choctaw body, on the other hand, maintained its cultural independence and was never dominated by the Creeks. In sharp contrast to the Creeks, whose national structure was built up by fitting numerous distantly related tribes into an artificial fraternal scheme, the Choctaw seem to have owed their sense of unity to an actual homogeneity in the Choctaw population, the occupancy of a common area, and the necessity to resist common enemies. They perhaps preserved the simplicity of culture existing among all Muskogean Indians in times long anterior to the formation of more complicated associations or confederacies.

There was no discussion.

NEW SERIES  
VOL. XXXVII. No. 954

FRIDAY, APRIL 11, 1913

SINGLE COPIES, 15 CTS.  
ANNUAL SUBSCRIPTION, \$5.00

*"Whatever our Intellectual Calling, no Kind of Knowledge is Antagonistic to it--all Varieties of Knowledge Blend with, Harmonize, and Enrich the one Kind of Knowledge to which we Attach our Reputation"--Bulwer.*

## ALLEN'S COMMERCIAL ORGANIC ANALYSIS

**Volume VII.** Vegetable Alkaloids, by G. BARGER; Non-Basic Vegetable Bitter Principles, by E. F. ARMSTRONG; Animal Bases, by A. E. TAYLOR, Animal Acids, by J. A. MANDEL; Cyanogen and its Derivatives, by HERBERT PHILLIP; Non-glucosidal Bitters, by G. C. JONES; Ptomaines, by G. BARGER; Lactic Acid, by W. A. DAVIS.

Cloth, \$5.00. Postpaid.

## THE PLANT ALKALOIDS

By Thomas Anderson Henry, D.Sc., F.C.S.  
*Superintendent of Laboratories, Scientific and Technical Department, Imperial Institute.*

In this volume will be found articles on all the more important alkaloids, describing not only the properties and the chemistry of these products, but also their occurrence, methods of estimation, and physiological action.

Octavo. Cloth, \$5.00. Postpaid.

## THE DEVELOPMENT OF THE HUMAN BODY

### A MANUAL OF HUMAN EMBRYOLOGY

By J. Playfair McMurrich, A.M., Ph.D.  
*Professor of Anatomy, University of Toronto, Formerly Professor of Anatomy, University of Michigan; American Editor of Morris' "Textbook of Anatomy."*

Fourth Edition, thoroughly revised. With 285 illustrations. Octavo; x+495 pages.

Cloth, \$2.50. Postpaid.

## ALCOHOLISM ITS CLINICAL ASPECTS AND TREATMENT

By Francis Hare, M.D.,  
*Medical Superintendent of the Norwood Sanatorium, Beckenham. Small Octavo. 280 pages.*

Cloth, \$2.00. Postpaid.

Synopsis of the Contents: Nature of Inebriety, Generally accepted propositions regarding alcohol, etc., Exciting, determining or accentuating factors of alcoholism, clinical classification of alcoholism, symptoms and complications, abstinence phenomena of alcoholism, Alcoholic epilepsy, Treatment (2 chapters), General results, etc. Index.

## FOOD IN HEALTH AND DISEASE

By Nathan S. Davis, Jr., A.M., Ph.D.  
*Professor of the Principles and Practice of Medicine in Northwestern University Medical School; Physician to St. Luke's Hospital, Mercy Hospital, and Wesley Hospital, Chicago; Member of the American Medical Association, American Climatological Society, etc.*

"The Volume is of much value, and should stimulate interest in a branch of therapeutics which has been greatly neglected."—MEDICAL RECORD, New York.

Second Edition. Thoroughly revised and rewritten, containing much new material. Octavo; xii+449 pages.

Cloth, \$3.50. Postpaid.

## THE HYGIENE OF THE NURSERY

By Louis Starr, M.D., LL.D.  
*Formerly Physician to the Children's Hospital, Philadelphia.*

Including the General Regimen and Feeding of Infants and Children, and the Domestic Management of the Ordinary Emergencies of Early Life, Massage, etc.

Eighth Edition. 26 Illustrations. 12mo; xi+331 pages.

Cloth, \$1.00. Postpaid.

In this edition the subject matter has been carefully revised and numerous additions have been made to keep the book abreast with recent advances in the methods of managing infants and children.

ONE of the primary purposes for which the American Breeders' Association was founded was to bring together on a common ground those who were approaching the problem of the improvement of plants and animals by breeding, on the one hand, from the side of practical breeding, and, on the other hand, from the side of the scientific study of heredity. One of these groups stands as the representative of the art or craft of breeding, and the other as the representative of the science of genetics. That each of these two bodies of men has something to learn from the other there is no doubt. Even with the continued and prosperous existence of such an association as this it is certain that actually there is far from being anything like as extensive a mutual interchange of knowledge and opinion between science and practise in breeding as would appear from every point of view to be desirable.

It will have been perceived by all who have followed my remarks so far that they have been commonplace to the point of utter banality. They constitute a thoroughly bromidic introduction to a conventional treatment of that time-stained and battle-scarred old theme of compulsory oratory, the relation of science and practise. Every one can foresee, with a moment's reflection, just what ought to come next, and next, and on to the end. At the outstart should be set forth the great achievements

<sup>1</sup> Papers from the Biological Laboratory of the Maine Agricultural Experiment Station, No. 44.

Address of the retiring chairman of the Animal Section of the American Breeders' Association at its Columbia, S. C., meeting in January, 1913.

of the science of genetics; then the tremendous possibilities thus opened out to the practical breeder, who in the near future will be able to soar from this scientific foundation to realms of wealth and power in the community hitherto possible only to the predatory classes; nevertheless, in a meek and humble spirit of gratitude engendered by the blessings which have been poured at his feet, he in turn contributes to the great cause of science by placing at the disposal of the geneticist the wonderful stores of experience he has accumulated; at the end should come an impassioned plea for "getting together" for the good of agriculture, humanity and sundry other things, which should, if well done, so titillate the emotions as to send everybody home uplifted, and, in general, determined to lead a better life.

I have sketched this little picture, which, if necessarily impressionistic, is essentially true, only to bring into sharp relief the intellectual junction point, at which we shall alight and change cars. Just because there has been so much perfervid oratory, loose thinking and cheap advertising of the achievements of men and institutions based on the ideal or assumed mutual interrelationship of the science of genetics and the breeders' art, it seems worth while to make a careful objective analysis of the actually existing relations between these adjoining fields of human endeavor. Such an analysis will be attempted in what follows. Specifically the question to which attention is invited is: What essential and fundamental contributions has genetics made to the *practice* of the breeders' art? Or, to put the matter in another way, what particular things does the most highly successful practical animal breeder do now which he did not do, or performed differently, before Mendelism was rediscovered or Darwin wrote?

It is generally agreed that during the past fifteen years there has been a great advance in our knowledge of the fundamental laws of heredity. Indeed, it may fairly be said that more has been gained in this regard within this period than in the entire previous history of this field of knowledge. The new method of investigating heredity which was given by Mendel's work has for the first time made a real analysis of genetic phenomena possible. It was a truly imposing array of organisms and characters which Major Hurst was able to list at the meeting in commemoration of Mendel at Brunn, as comprising those attributes of organisms about the inheritance of which something *definite* is *known*.

There is a very widespread assumption that coincident with this advance in our knowledge of the fundamental laws of inheritance there has been an equal advance in the practical art of breeding. This has perhaps resulted from the somewhat over-enthusiastic prophecies of the early Mendelian workers. Many will remember the glittering possibilities set forth to the practical breeders in the early meetings of this association. They were told in effect that at last the key to the genetic riddle had been found; that by the application of these simple Mendelian laws existing races of animals could be brought up to desired ideals with more certainty and despatch than had hitherto been possible, and that new races could be created which would surpass in usefulness anything now existing. There was, of course, an element of truth in all this. But it raised unwarranted hopes in the minds of many laymen. The apparent failure of these prophecies to be realized has probably done real harm to the cause of science in the minds of some practical men—representatives of the class to which in last analysis science must look

for its material support—and very generally has led animal breeders to under-rate the real value of Mendelian investigations.

It is permissible to think that the fundamental error involved was in the assumption we are all inclined to make that any distinct advance in science necessarily means an equally marked and immediate advance in the practise of the associated art or craft. It is extremely difficult for the man of the laboratory or the study, as he takes a broad view of the history of the industrial arts, and sees that great progress there has rested upon fundamental scientific discoveries, to realize that the art of breeding differs essentially in this respect from the industrial arts. The breeding of animals by man for more or less definite purposes goes back to prehistoric times. Practically as soon as primitive man began the domestication of animals he must perforce have begun, in greater or less degree, to control their breeding. Having started thus early, the craft of breeding had attained a relatively high degree of development centuries before any attempt was made to formulate the scientific principles of genetics. As an example may be mentioned the breeding of horses in England. It is customary to think of "stallion laws," aimed at the improvement of the horses of a state, as very modern and American, and an indication of the influence of the science of breeding on the practical craft. But three hundred and seventy odd years ago, in the reign of Henry VIII., there was passed a "bill for the breed of horses," which in its preamble stated that:

Forasmuch as the generation and breed of good strong horses within this realm extendeth not only to a great help and defence of the same, but also is a great commodity and profit to the inhabitants thereof, which is now much decayed and diminished by reason that, in forests, chases, moors and waste grounds within this realm, little stoned horses and nags of small stature and of little

value be not only suffered to pasture thereupon, but also to cover mares feeding there, whereof cometh in manner no profit or commodity.

In order to prevent the multiplication of poor specimens section 2 of this law provided that no uncastrated stallion two years or more old which was under 15 "handfuls" high should be allowed to graze on common or waste land in certain counties. Further it was provided in section 6 that all forests, chases, commons, etc., were to be "driven" at a stated time in the year (just preceding Michaelmas day) and all horses, mares and colts which were not of good quality, or did not promise to become or to produce serviceable animals, were to be killed.

The fact is that the practise of the art of animal breeding, so far from languishing, for want of instruction from the science of genetics, is actually immeasurably in advance of that science. The geneticist who is disposed to think otherwise should visit a great horse, or cattle, or even poultry show, and then permit himself to consider candidly the question whether with all his science he could himself breed, or tell any one else how to produce, *finer* specimens than he will see there. Yet by hypothesis that is exactly what he ought to be able to do, if genetics is to set up as a teacher and guide to the best practical methods of live-stock breeding.

It is capable of abundant historical proof that many years ago, before the beginning of the world movement towards agricultural education, experimentation and the grounding of a science of agriculture in general, there were in existence individual animals (even flocks and herds), and strains of seeds or farm crops which were probably intrinsically as fine, as productive, and generally as excellent as any that we know to-day. Given as intelligent care and feeding as our prize-winning animals

and plants now get, there is every reason to believe that they would have equalled or surpassed our finest specimens of to-day. Some specific examples may be cited. Mr. Geo. A. Scott,<sup>2</sup> of Nashville, Tenn., had in 1863 "a common scrub cow" which produced in one year 1,447½ gallons of milk. Taking the weight of one quart of milk at 2.15 lbs. as sufficiently close for practical purposes, this gives a record of 12,448.5 lbs. of milk for the year. This is a respectable figure even for present standards. Going back a half century earlier we have the record of a Sussex cow<sup>3</sup>: "a cow not of either of the highest improved English breeds—long horns or short horns; but of the proper old Sussex breed." The following record is of her production in five successive years beginning in 1805. I have transposed quarts to pounds by the use of the factor given above—2.15.

	Weeks in Milk	Lbs. of Milk	Lbs. of Butter
First year . . . . .	48	10,580.2	540
Second year . . . . .	45½	8,894.6	450
Third year . . . . .	51½	12,366.8	675
Fourth year . . . . .	42½	9,070.9	466
Fifth year . . . . .	48	11,543.4	594

Facts of the same sort are at hand for crops. Justin Ely, Esq., of West Springfield, Mass., in 1816, raised 50 bushels of wheat to the acre. Col. Jas. Valentine, of Hopkinton, raised 128 bushels of "Indian corn" to the acre. Payson Williams, Esq., of Fitchburg, raised 614 bushels of potatoes to the acre, and James Whitton, Esq., of Lee, raised 85 bushels of oats to the acre. The average yield of oats to-day is approximately 36 bushels to the acre. The Maine Agricultural Experiment Station, in its tests of the best commercial varieties of

oats procurable in this country and Europe, has never been able to obtain a yield per acre of more than 76 bushels.

I have elsewhere discussed records of egg production in poultry in this connection. From 1836 there is an authentic record of crested Polish fowls producing an average of 175 eggs each per year. This was long before the trapnest had been discovered.

Too much stress, of course, should not be laid on such examples as these. They do not indicate that there has been no advance made by the breeder in the qualities of domesticated animals and plants during the last century. The *average* quality of live stock and of crop plants is constantly improving, not only as a result of breeding, but also because of better and more widely disseminated knowledge of how to provide the food and environmental conditions best suited to bring to full expression the potential hereditary capabilities<sup>4</sup> of the individual. I think that such records, however, do fairly indicate that in the practise of the art of breeding there has been no such marked fundamental advance in recent years as there has been in the science of genetics. By empirical methods man has been steadily improving the quality of live stock for centuries past, and long ago a *relatively* high level was reached by the most skillful breeders.

Purely empirical methods are wasteful and slow in operation, but they may attain excellent results. When they are successful it is obviously because at just that point the practise was, by chance, in exact conformity with the underlying principle or law concerned. More generally it may be said that all progressive success of em-

<sup>2</sup> *The Cultivator and Country Gentleman*, Vol. 28, p. 401, 1866.

<sup>3</sup> *Massachusetts Agricultural Repository and Journal*, Vol. IV., No. 4. Cf. also *New England Farmer*, Vol. III., p. 305, 1825.

<sup>4</sup> Consider in this connection the practises of the real expert in making world's records for milk and butter fat production in the seven- and thirty-day advanced registry tests of the Holstein-Friesian breed.

irical methods depends on a gradual elimination of those operations or practises which do not accord with basic natural laws. In the consideration of the science and practise of breeding this has sometimes been forgotten. It is difficult to remember always that a law of nature may be presumed to have been in operation before its discovery. If Mendel's law represents a real and fundamental law of nature, as certainly appears to be the case in the light of present evidence, it is quite certain that it did not begin operation in A.D. 1900. Whatever of success has been attained during centuries past in the breeding of improved strains of animals and plants, must have been attained by methods and practises which were not violently in discord with Mendelian principles. A nomad Arab may never have heard of the principle of segregation, but none the less he had to reckon with the phenomenon in breeding his horses.

Looking at the matter in this way, the reason is clear why the rediscovery of Mendel's work and the brilliant genetic researches which have followed did not and could not have had any profound revolutionary effect on the *practise* of the animal breeders' art. By years—even centuries—of "trial and error" methods, breeding practise has been brought into rather close conformity with the basic laws of heredity. The discovery of some of these laws by the geneticist could not radically change the breeder's way of attaining results.

What then has the rapidly developing science of genetics done for the breeder and what can it do? Still looking at the matter from the standpoint of the practical animal breeder, it must be agreed, I think, that the chief contribution of recent discoveries in the field of inheritance is that they have brought to light and fairly es-

tablished certain general principles which enable him in greatly increased measure to understand and interpret his methods and his results.<sup>5</sup> This may seem too mild a statement of the practical value of genetic science to the animal breeder. It undeniably does lack the grandeur of the vision sometimes opened out by the extension lecturer in his zeal to inspire the farmers to better things, and at the same time pave the way to increased appropriations for his institution. But to help one to understand and to interpret is, after all, no mean achievement. It signifies that, with much economy of effort, the successful breeder may dispense with the merely trivial and unessential in his empirical methods, and more directly and uniformly attain the same or a greater measure of success than before. To his less successful brother and the beginner, it means a surer and more rapid guide than the old tradition based on empiricism. It is certain that the young man starting out to-day to be a breeder of fine cattle, of fine horses, of fine chickens, will attain his goal much sooner if he thoroughly understands the meaning of those laws of inheritance associated with the name of Mendel.

The most important general principles which the scientific study of genetics has firmly grounded are, it seems to me, these:

(a) That the fundamental basis of all inheritance is to be found in the germinal constitution of the individual rather than

<sup>5</sup> This is of course to be understood as a general statement. There are now a few specific instances, and in time there will be more, where the geneticist has been able to show the breeder precisely how to attain a particular result in breeding commercially for a particular quality, which result he had only hitherto been able to obtain by chance. In no such case, however, so far as I am aware, has the new method been so essentially different from former practise as to be fairly regarded as "revolutionary."

in the body or soma. Those qualities alone are inherited, which are innate in the germ cells, the ova and the spermatozoa. Here only can the breeder find the means with which to accomplish his ends. However interesting theoretically may be those rare and still doubtful cases in which extraordinary influences acting upon the body under the controlled and special conditions of the laboratory may perhaps influence the germ cells through the soma, they have no bearing on the practical conduct of the breeders' craft. Genetics has demonstrated that he may cast aside, for once and all, that mass of tradition and superstition which assumes that influences specifically affecting the body will specifically modify subsequent generations. Has not genetics done breeding a service of great value in freeing it of the sinister influence of "telegony," "saturation," "maternal impressions" and similar sorts of nonsense?

(b) That specific characters or groups of characters, in the great majority of cases and perhaps all, are inherited as discrete and definite units. If one mates a pea-combed fowl with a single-combed, all the offspring will have pea-combs. This result occurs whether the pea-combed parent is a Game or a Brahma; whether it is a male or a female; whether it is a strong, vigorous individual, or the sickliest, weakest scrub in the flock. In other words the *kind of bird* it is whose germ cells carry the potentiality to make pea-combs develop in the offspring, so far as we now know has nothing to do with the *specific* result (*i. e.*, the production of a *pea* comb, rather than a single, a rose, or any other kind). Comb form is inherited as a discrete unit uninfluenced by the individual's other attributes. This discovery that characters are inherited as separate units—and no principle of genetics is more firmly grounded than this—gives the breeder a

totally new concept of the meaning of "purity" of blood in breeding. We see now that properly (*i. e.*, biologically) one can only speak of an animal as being "pure-bred" when he specifies the particular *character* to which he refers. A chick may be the veriest mongrel in all other respects and yet carry in the germ cells only that potentiality in respect to comb form which leads to the development of a pea-comb. Then however much of a mongrel it may be in respect to all other characters, it is "pure" and "pure-bred" so far as concerns comb. Is it not a contribution of moment to the breeder to have demonstrated that in his breeding operations he may safely and surely deal with individual characters, and groups of correlated characters as units?

(c) That in a very great range of cases, perhaps in all—the number of known cases daily grows larger—the Mendelian law of segregation and recombination of characters operates. In the formation of the germ-cells of an individual there is a sorting out or segregation of the hereditary characteristics contributed by the father and the mother and a readjustment of these into all of the combinations, both old and new, which are mathematically possible. What may be the precise cellular mechanism or basis of this wonderful process is not altogether certain, but the phenomenon itself is as certain as the phenomenon of gravitation. It operates as well in regard to the minutest heritable differences in the pedigreed specimens of the same sub-breed as in the wide differences of true hybridization. Properly understood, it enables the breeder to interpret and weigh the results of his breeding operations, and so intelligently to plan the next steps with a certainty and precision hitherto unattainable. Is not this a real contribution of science to practise?

(d) That the germinal bases of heritable unit characters can be changed or altered in any respect, only with the greatest difficulty, if at all. It is, I believe, fair to say that there is at present no critical, unchallenged evidence that any alteration can be produced. This matter has recently been discussed in a most able manner by East.<sup>6</sup> The weight of evidence at present indicates that selection does not act in the manner it was long supposed to, in accordance with Darwin's interpretation. It appears that selection, however stringent or long continued, is powerless to alter in any way the original potentialities of the germinal basis of a unit character. Selection appears to be essentially a process of sorting out from a mixture of heritable variations what is already there, and not a germinally creative or germinally additive process.

So far this discussion has been approached from the standpoint solely of animal breeding. It is perhaps allowable, even before this animal section, to digress for a little and discuss plant breeding. The ultimate objective point of the animal breeder is the same as that of the plant breeder, namely the greatest possible improvement of animals and plants and their adaptation to the needs of man. The practical method of working towards this goal is, however, somewhat different in the two fields. The animal breeder almost exclusively works towards the amelioration of existing fixed and "pure" breeds. Especially among the larger domestic animals such a thing as a *new* breed is brought forward by the breeder only on very rare occasions. Almost all of our existing breeds of horses, cattle, sheep and swine have long histories as "pure breeds," and no new ones are being added now. With smaller animals such as poultry the case is of course

somewhat different. There we have no registered pedigrees and, with some difficulty, new breeds may be launched.

The plant breeder, on the other hand, makes nearly all of his improvements by the production of new varieties. This he does either by hybridization, actually building up a new type, or by isolation of superior pure-breeding forms from already existing mixtures. He is not hampered by a body of tradition that only the "pure bred" is of any particular value. Almost if not quite every one of the most valuable strains of agricultural plants to-day carries the "bar sinister." To the animal breeder they would be "grades" or "crosses" however gametically pure and only with the greatest difficulty would ever have gained a chance to show their worth.

No one would deny that the systems of registry for live-stock and the exploitation of the "pure-bred" have been of great value in the development of the animal industry of the world. They certainly have; and every day the economic importance of the system becomes greater, for obvious reasons. All systems of pedigree registration operate economically precisely like a monopoly. As such a plan of developing the live-stock industry of a country grows, the more difficult does it become for a *new* creation of the breeder to get a foothold. If it is new, it is by definition not "pure-bred," because if it were "pure-bred" it must belong to one or another of the established breeds. But anything not "pure-bred" has no recognized standing, or market value. Without regard to the merits of the individual the mere fact of pedigree registration adds a definite and not inconsiderable amount to the monetary value of an animal. In last analysis this fact is to-day one of the strongest arguments which can be made to the farmer in favor of keeping "pure-bred" animals.

<sup>6</sup> *American Naturalist*, 1912.

What has just been said is not intended in any way to criticise, or belittle the importance and value of the "pure-bred" registry system of developing the live-stock industry of the world. I merely wish to point out that when he adopted the system, the animal breeder took upon himself along with the advantages certain very real restrictions to the freedom of his breeding operations, which the plant breeder has escaped. The animal-breeding industry of the world has developed as a system of pedigreed aristocracy. The plant-breeding industry is developing as a democracy. The "social position" of a horse or a cow is primarily determined on the basis of whether it had a grandfather or not. A variety of oats takes its place in the world by virtue of its own inherent qualities, with no questions asked about forebears or the orthodoxy of their marital relations. Both aristocracies and democracies have their advantages and their disadvantages as social systems. These merits and defects are just as real and effective in their operation whether the ultimate vital unit of the system be a man, a cow or an oat plant.

Owing to the essentially different conditions and methods of work which obtain in plant breeding, this field is able to reap more direct benefits of a practical character from the advances which have been made in the science of genetics, than is animal breeding. In the creation of new races by hybridization the plant breeder can and does take Mendelian principles as a direct and immediate guide. He has made Mendelism a working tool of his craft.

To conclude: What I have tried to do in this paper is to discuss the relation between the science of genetics and the practical art of breeding as they actually have developed and now exist. Your attention has been directed to the obvious fact that animal breeding has, without the aid of genetic

science, attained an extremely high level of achievement. Empirical methods can only have been successful when they were fundamentally in accord with natural laws, and it is therefore not to be considered surprising that the recent discoveries of world-old genetic laws have not radically modified the successful animal breeders' methods. In pointing out that a scientifically trained geneticist is not as yet an absolutely indispensable necessity on a successful animal breeding farm I have no thought or desire to belittle the importance of the science of genetics. My zeal and enthusiasm for the advance of knowledge in this field know no bounds. This attitude, however, furnishes no reason that the geneticist should delude himself, or by rash statements hold out false hopes to the breeder, as to the immediate practical importance of some of the recent developments in the science of genetics. All knowledge is potentially useful, but the fundamental reason for undertaking and encouraging research in genetics, or anything else, is not because what one gets may be useful, but because it is *knowledge*.

RAYMOND PEARL

MAINE AGRICULTURAL EXPERIMENT STATION

#### THE METAMORPHOSIS OF THE CARNEGIE FOUNDATION

THAT part—a relatively small part—of the new annual report of the Carnegie Foundation which deals with the affairs of the foundation itself, is significant chiefly as showing that the president of the foundation, at least, has already abandoned most of those principles which at the outset were generally understood to govern the foundation's policy with respect to retiring allowances. It is worth while to recall what some of those principles were.

1. The primary purpose of the pension system was to be, not to relieve deserving and necessitous college teachers in their old age, but to better the profession as a whole, "to attract into it increasing numbers of strong

men"<sup>1</sup> and to increase its "social dignity and stability," by increasing the eventual reward of those who continue long in it and reach professorial rank in institutions of sound educational standards. This was laid down as one of the "two fundamental principles" in the first annual report. President Pritchett therein wrote:

In the long run, men's personal preference for the work of the teacher . . . can not be depended on to secure an adequate supply of the best men. This fact the older European countries long ago recognized, and in order to secure for the place of teacher the best men, they have sought to dignify the profession of the teacher by the highest social and official honors; and they have sought in addition to strengthen it by larger financial rewards. And inasmuch as the salaries of the teachers can not be made equal to those of outside professions this reward has come, in the main, by the establishment of a system of pensions. . . . In other words, the first and largest ground for the establishment of systems of retiring pensions for teachers has been found in a wish to strengthen the teaching profession.<sup>2</sup>

2. As a necessary consequence of the preceding, a second principle repeatedly enunciated in the earlier reports was that the retiring allowance "should come as a matter of right, not as a charity." President Pritchett wrote in 1906:

No ambitious and independent professor wishes to find himself in the position of accepting a charity or a favor, and the retiring allowance system simply as a charity has little to commend it. It would unquestionably relieve here and there distress of a most pathetic sort, but, like all other ill-considered charity, it would work harm in other directions. It is essential, in the opinion of the trustees, that the fund shall be so administered as to appeal to the professors in American and Canadian colleges from the standpoint of a right, not from that of charity, to the end that the teacher shall receive his retiring allowance on exactly the same basis as that upon which he receives his active salary, as a part of his academic compensation.

3. One of the purposes especially emphasized in the first report was that of "freshen-

ing the work of the colleges themselves by enabling them to put new men into the places of those whom old age or disability has rendered unfit for service."<sup>3</sup>

4. Pensions were to be granted on three grounds, old age, length of service and disability. Sixty-five years was specified as the limit of age and twenty-five years in professorial grades "as the limit of service upon which a pension may be earned." Widows of professors were to receive one half the allowances to which their husbands would have been entitled.

Upon these points the opinions of President Pritchett have by this time singularly changed. It will be convenient, in noting these changes, to take up the points in reverse order.

4. (a) The service-pension provisions of the foundation were, as is generally known, abolished without warning in 1909; that is an old story, little creditable to the executive authorities of the foundation, to which it would not now be needful to recur, did not President Pritchett repeat certain aspersions (already made in the fourth report) upon the members of the profession who became entitled to, and accepted, those pensions prior to 1910; and did he not misrepresent the original policy of the foundation in this matter. Dr. Pritchett now writes:

The service-pension rule was adopted by the trustees under the assumption that but few applications would be made under it, and that these would be in the main applications from men who were disabled for further service. The intention was, in fact, to use the rule as a disability provision. The outcome showed what might have been clearly foreseen at the beginning, that college presidents and college teachers can no more rise above the ordinary appeal of self-interest than other educated and intelligent men. . . . It has been discouraging at times to find men in the early fifties, in the prime of health and strength, applying for pensions upon trivial and selfish grounds in order to escape from teaching.<sup>4</sup>

<sup>1</sup>First report, p. 37.

<sup>2</sup>*Ibid.*, p. 31.

<sup>3</sup>*Ibid.*, p. 7.

<sup>4</sup>Seventh report, pp. 82-84.

This passage is at once a misleading account of the original service-pension policy of the foundation, and a peculiarly discreditable act of injustice to the seventy gentlemen who received service pensions (in "accepted institutions") under the former rules. It is to be supposed that if the trustees had in 1906 the intentions now retrospectively ascribed to them, they had sufficient access to dictionaries of the English language to be able to give some expression to those intentions. But in fact, they gave no hint then, or in the following years, that they meant the service-pension to be subject to any other limitations than those clearly specified in the rules; and they plainly indicated they did *not* regard it as a disability pension, since, in the annual records of retiring allowances granted, three classes have from the first been distinguished—those granted "on basis of age," "on basis of service," and "on basis of disability." What the foundation did was to declare that a certain number of years constituted "the limit of service upon which a pension may be earned," the pension coming then "upon exactly the same basis as" the recipient's "active salary." Having offered pensions to a number of men on these definitely specified terms, President Pritchett now publishes reflections upon them for accepting the pensions upon those terms. It can not even be said (what Dr. Pritchett implies) that the recipients of service pensions had reason to know that they were taking "for their greater comfort pensions that would mean great relief to more needy teachers." For the first report gave assurance that the income was sufficient to provide for all professors in many more institutions than were on the accepted list; and that it was even hoped that after trial "a more generous scale of pensions" than that then in force could be adopted, "either by extending [*sic*] the limit of age or of service, or by increasing the amount of the individual pension."

(b) It now becomes evident that, if the future policy of the trustees is to be guided by the views of the president, the old-age pension also is destined to great modification, and

<sup>6</sup> First report, p. 15.

probably to abolition. Dr. Pritchett now writes on this as follows:

The experience of the foundation shows that the minimum age limit should be set higher than sixty-five. . . . Just what age is the best to set as a minimum limit it is difficult to say. The whole matter comes back to a *conception of the pension which is somewhat different from that which we all very naturally entertained at the beginning, that is, that the pension is not intended to assist the man of strong body and mind to get out of teaching at any assigned age, it is to take care of him when his powers fail and he can no longer do his work well.* To raise the limit of age works no hardship to the man who is broken in health at sixty-five. Such a man would be retired on the ground of disability. One places a different ideal before the teacher, moreover, when he suggests *retirement on the ground of approaching weakness rather than on the ground of a definite limit of age.*<sup>8</sup>

Thus the entire system of professorial pensions may be expected soon to be based upon only one—and that the last—of the three grounds originally recognized, viz., disability.

3. There naturally goes with this change an abandonment of the purpose of "freshening" the teaching in the colleges by facilitating the retirement (under the age limit) of men not physically disabled but of impaired efficiency.

The anticipation of college presidents that inefficient men could be disposed of by a pension has proven another delusion.<sup>7</sup>

2. As the foregoing suggests, Dr. Pritchett has already very nearly come to look upon the foundation over which he presides as essentially eleemosynary in its purpose. With some indirection, yet unmistakably enough, he intimates that, in his opinion, teachers possessing "an adequate or modest income" can not with entire propriety accept pensions. He finds that the teacher does *not* "receive his retiring allowance on exactly the same basis as that

<sup>8</sup> Seventh report, p. 69; italics mine. It should be added that President Pritchett regards the plan of contributory pensions as the ideal one, though he does not definitely urge its adoption by the foundation.

<sup>7</sup> Seventh report, p. 84.

upon which he receives his active salary." President Pritchett is, indeed, not quite able to forget his early insistence upon the principle that the foundation's pensions "come as a right, not as a charity." He therefore repeats this, and straightway unsays it.

While the trustees have sought, and rightly sought, to have teachers in the accepted institutions feel that the pension is a thing earned and not a charity, nevertheless it ought to be said that the acceptance of it does not stand upon quite the same basis as the acceptance of a salary, nor have teachers appreciated quite fully that their own attitude towards this gift and its use would have its effect upon educational giving and the estimation that the world puts upon the motives and ideals of teachers. The foundation would not in any respect diminish the feeling that the teacher, in an accepted institution, may accept the pension as a right, not as a favor. None the less it remains true that this is a free gift, and that the well-to-do man who accepts it thereby makes it impossible to extend the help of a pension to one who really needs it.\*

A Carnegie pension, therefore, is hereafter to be regarded as a "right" which is at the same time "a free gift"; it is a thing earned which yet one ought not to accept if one already has a competency—a paradoxical entity indeed. President Pritchett does not thus far indicate that the trustees, before awarding pensions, mean to use the methods of the charity organization society in order to establish the fact of the applicant's poverty; though the past history of the foundation justifies no confidence that the rules will not in time be changed so as to provide for something of this sort. Nor, if poverty is really presupposed, ought the manner of establishment of the fact to be left undetermined. But for the present the question is left "for the individual himself to settle." The individual, however, receives a plain hint that he is expected to settle it only in one way. Thus the basis upon which pensions may, in President Pritchett's view, hereafter legitimately be applied for is not service rendered, but destitution. He would have them go exclusively to aged professors who are also disabled

and who "really need" such a "free gift" for their support, and to widows similarly in need.

1. All this means, of course, that the purpose which the early statements of the foundation gave as its chief reason for being has now been discarded altogether. This follows both from the particular nature of the changes already made or foreshadowed, and also from the fact, now abundantly evident, that, in general, constant change in its purposes and its rules is the most distinguishing feature of the foundation's conduct. The reward to be expected by the reasonably successful and thrifty member of the teaching profession will be in no degree increased, if the system is put upon the basis which President Pritchett now recommends. The "social dignity" of the profession will be in no way enhanced by the maintenance of a fund for the relief of destitute and disabled professors and their relicts, least of all, if it is to continue to be a feature of the foundation's policy to publish periodic animadversions upon persons who have accepted pensions to which the plain language of the rules seemed to entitle them, and if the annual reports are regularly to contain melancholy reflections on "the darker side of pension administration" and the surprising "selfishness" of many teachers. "Increasing numbers of strong men" are little likely to be attracted into the profession in their twenties by the expectation of receiving a "free gift" at nearly seventy, on condition that they are then incapacitated and without means of support—especially when they know that the corporation promising this gift reserves and frequently exercises the right to disappoint the expectations which it has aroused.

While the new report thus manifests a reversal of the principles originally adopted on these four essential points, it records one change which is more in keeping with those principles than has been the practise heretofore prevailing. Hereafter no new grants are to be made to persons not in "accepted institutions."

Though the relation of cause and effect is not altogether plainly avowed, the probable

\* *Ibid.*, p. 83.

reason for all five of these changes of heart is to be sought in the foundation's financial situation. The actuarial calculations upon which the trustees based their original plans have proved far too sanguine. The first report estimated that the average pension under the rules then in force would be less than \$1,450. The present general average is \$1,677; of those in accepted institutions, about \$1,750. If it were not for the obligations assumed towards persons not in accepted institutions, even with this increase the pensions paid to the present number of professors or widows of professors in such institutions would leave a surplus out of the annual income of about \$200,000; as it is, there is an accumulation in the past year of some \$42,000. The present close approach of the foundation's expenditure to its income is thus chiefly due to the policy of making special grants, hereafter to be abandoned. But even with this charge in process of elimination, the time when claims for pensions, valid under the present rules, will far exceed income is clearly in sight. It was expected in 1906 that an income of \$500,000 would maintain an adequate pension system for between 100 and 120 colleges—as many as were thought likely to come upon the accepted list. At present the providing of pensions—with the service-pension abolished—for 72 institutions only, requires an expenditure of \$478,440; and it is estimated that “at the end of a generation,” if the existing rules should remain unchanged, the claims to pensions *coming from these institutions alone—assuming their faculties to remain stationary in number and the average age of retirement to be sixty-nine*—would call for annual payments of \$1,375,000. The foundation's total income, “when the whole of the gifts already made to it by the founder are paid in, will amount to approximately \$800,000.”<sup>9</sup> Consequently, if the endowment is not increased, the rules for the granting of pensions will inevitably have to be so modified as to reduce greatly the average amount allowed, or the number of valid claims, or both.

In so far, then, as the changes of policy now

suggested are designed to meet this future contingency, they may claim the justification of necessity. In attempting to provide pensions, upon the excellent principles originally proposed, for so large a number of institutions, the foundation was attempting a thing impossible with the funds at its disposal. That its impossibility was not foreseen at the outset by the officials of the foundation is amazing. It is true, as President Pritchett constantly remarks, that no complete data bearing upon exactly the foundation's problem were available in 1906. But most of the recently gathered facts with regard to the number, rate of increase of number and of salaries, and age-distribution, of teachers in accepted institutions, upon which facts the present calculations are based, could equally well have been obtained six years earlier; and their indispensableness was then equally obvious. The report of Messrs. Pritchett and Vanderlip<sup>10</sup> upon which the original estimates appear to have been largely based, actually contained no reference to the all-important factor of age-distribution in the case of men not yet of pensionable age. It implied, for example, that the number of professors over 65 in 1905 would approximately indicate the number of the same class in subsequent years. It would be hard to imagine an actuarial error more glaring or more easily avoidable. This error, and the insufficiency of the foundation's endowment for its announced intentions, were clearly pointed out by Professor Cattell in *SCIENCE* four years ago.

If, then, the foundation (or its president) has within six years abandoned most of its original ideals, and if the university teachers of America have generally lost confidence in the stability of the foundation's policy and the trustworthiness of its promises, this disappointing outcome is the natural consequence of the initial adoption of a program manifestly impossible with the available endowment. The mistake in that program did not consist in its essential principles; it consisted in making the rules completely retroactive; in authorizing special grants; and above all in

<sup>9</sup> *Ibid.*, p. 92.

<sup>10</sup> First report, pp. 10-16.

attempting to provide for too many colleges. President Pritchett in his first report justly remarked:

No one can doubt that the establishment of an effective system of retiring allowances in one hundred institutions will contribute vastly more to the introduction of the retiring-pay principle in American education than the maintenance of a charitable fund for a much larger number of institutions.

But the "one hundred" in this sentence was itself far too large a number. The final result, now definitely foreshadowed, of this original over-estimate seems likely to be that the foundation will in time be nothing more or less than a charitable fund for from seventy-five to one hundred institutions.

A charitable fund, no doubt, will have its uses; it will mean relief from anxiety and distress for a considerable number of worthy and unfortunate people connected with our colleges. But it will render none of those services to "the advancement of teaching" which were once understood to be the chief function of the foundation.

It is, however, possibly even now not too late for a return to first principles—though it, like any other course of action now open to the foundation, would probably involve some hardship. Let the foundation add no more colleges to its "accepted list"; let it, if actuarial analysis should show this to be feasible, announce that all professors who now have legitimate expectations of pensions under the present rules will have those expectations duly realized; or if, as is probable, this is financially impossible, let it provide that at least all now over forty-five or fifty years of age will have their claims met as they mature. But for all others let the present rules be temporarily abrogated. Let the foundation then select carefully a much smaller number of colleges, on the basis of educational standards, geographical situation, and certain other considerations. Let it then, after thorough actuarial study, establish for these institutions a stable system of retiring allowances, *upon the general principles which the foundation first laid down*, with the further requirement that

the institution shall contribute a part of each pension, and without requiring absolute cessation of academic activity. These things done, the great initial error would be largely corrected, and the foundation's original purposes would be realized in the measure which its endowment permits.<sup>11</sup> Such a plan would indeed do more not only to establish the "retiring-pay principle," but also to increase the attractiveness, the dignity and the efficiency of the college-teaching profession, than would "the maintenance of a charitable fund for a much larger number of institutions."

It may be, however, that a still more thorough statistical analysis than has yet been made would show that the resources of the foundation will not support such a system for more than an extremely small number of colleges. If this should prove to be the case, there might be defensible grounds for a decision to maintain thereafter, for a larger number, disability-pensions only. But if the foundation should be reduced to this necessity, pensions should be granted for disability (to persons genuinely committed to the teaching profession) at any period of life, or to professors' widows, whatever the age of the husband at the time of death. A disability-pension system is likely to serve the most urgent need precisely in case of break-down or sudden death in middle life, while the family suffering such misfortune still has young children to be educated and before the accumulation of considerable savings has been possible. Furthermore, whatever pensions are provided for should be granted to legitimate applicants without special presumption of poverty. Such a plan, in my opinion, should be the last resort of the foundation; and if adopted it should be frankly recognized as what it is. Yet even it would be preferable to a scheme of the equivocal sort which the president of the foundation now appears to regard with favor.

<sup>11</sup> Another possible solution which merits consideration would be to use the income to aid institutions to establish pension systems. The reasons given (p. 79) for the original rejection of this plan do not seem conclusive.

But the most needful change in the pension policy of the foundation is a cessation of change. The worst possible trait in any system of annuities or insurance is the trait which has hitherto conspicuously characterized the administration of those who have had Mr. Carnegie's great gift in their charge—untrustworthiness. Whatever else it is, a pension system should be a thing which can be depended upon, to which men can adjust their plans with confidence. All its dealings should be marked by an *uberrima fides*. Its rules should be definite and comprehensive; and they should not subsequently have read into them meanings contrary to their natural sense. It is imperative, therefore, that the foundation take the necessary measures to ensure the stability of its policy. It should first of all determine with the utmost care and thoroughness what it is financially able to do. It should thereafter confine its promises within the limits of its possibilities. It should then keep the promises it makes.

ARTHUR O. LOVEJOY

GEORGE HAROLD DREW

GEORGE HAROLD DREW, B.A., of Cambridge, one of the most brilliant of the younger biologists of England, died suddenly on January 30, 1913.

He was the only son of George Samuel Drew, Esq., of Paignton, Devon; and was born on October 23, 1881, and educated at New College, Eastbourne.

He was entrance exhibitioner at Cambridge in 1900 and was elected in June, 1901, to a scholarship in the university, where he paid special attention to the natural sciences and to the more scientific aspects of the medical courses. In 1906 he obtained a scholarship in St. Mary's Hospital, and in 1908 he studied in the Marine Biological Station at Plymouth and was also lecturer in biology in the Plymouth Technical School. In 1910 he was appointed Beit memorial fellow in medical research for the zoological department of cancer, and in 1912 he was elected to the John Lucas Walker studentship for pathology in the University of Cambridge, and on January

1, 1913, he was appointed research associate in the department of marine zoology of the Carnegie Institution of Washington.

He was distinguished not only for his remarkable breadth of knowledge, but even more so for a rare aptitude and insight into methods of research which, had his life been spared, would have led to his name being known among the very few of England's great men of science; but in the springtime of his high promise he passed away and the all but unheeding world has lost a great leader who was to be.

He was the author of only fifteen papers, yet among them are some notable contributions to science.

In coral reef regions naturalists have long been familiar with the vast areas covered with finely divided limestone which has commonly been called "coral mud." In 1910, however, Vaughan stated that these limestone muds appeared to be of chemical origin, and in 1911 Drew discovered that there is in the warm surface waters of the tropical Atlantic a bacillus which is exceedingly abundant and which denitrifies the sea water, thus enabling the dissolved carbon dioxide to combine with the calcium and to form a precipitate of calcium carbonate.

Thus the vast beds of limestone which in coral reef regions are often hundreds of feet in thickness and thousands of square miles in area are formed mainly through the activity of Drew's bacillus.

Moreover, the presence of this denitrifying bacillus in tropical seas accounts for the paucity of sea-weeds in the warm oceans, and the blue color of "coral seas" may in some measure at least be due to the presence of the finely divided particles of calcium carbonate suspended in the water.

Recent studies by Vaughan appear to indicate that oolite is ultimately formed from this precipitated calcium by attraction of the particles to the films of gas bubbles, or to solid nuclei, in the manner described by Linch.

Drew's interest, however, extended to subjects other than those of oceanography; for

his remarkable work in the production of ciliated cysts, and other abnormal growths due to artificial stimulation in *Pecten* and other marine invertebrates led to his being appointed to the Beit fellowship for the study of cancer.

He was, however, far more than a young man whose ability, training and energy inspired confidence respecting his ultimate high position in attainment, for he was an English gentleman, simple in manner, generous in spirit; a charming, brilliant companion, a warm-hearted friend, and above all one whose aim it was to give to the world all that lay within his power to bestow as a servant of the high ideals of civilization.

ALFRED G. MAYER

#### FUR SEAL LEGISLATION

THE following letter has been addressed to members of congress under date of March 31, 1913:

The fur seal legislation of the 62d Congress has been left in very unsatisfactory shape. A treaty was entered into on July 7, 1911, by the United States, Great Britain, Japan and Russia, for the suspension of pelagic sealing for fifteen years. This treaty provides protection for the mother seal on her migration and feeding journeys and guarantees the future prosperity of the herd. The treaty was promptly ratified by the Senate, but in the act of August 24, 1912, designed to give effect to this treaty, was included an amendment suspending land sealing—the killing of the superfluous males—for five years. The significant relation of this amendment to the treaty is that the United States agreed to share its land catch with Great Britain and Japan in return for the abandonment by their citizens of the pelagic industry. We are as firmly bound to continue land sealing and share its product as are Great Britain and Japan to prohibit pelagic sealing. Dissatisfaction naturally results from our action. Abrogation of the treaty would be followed by resumption of pelagic sealing, with ultimate destruction of the herd. Even if the treaty be not openly broken, our indifference to our obligations warrants like indifference on the part of our neighbors in enforcing prohibition, leading to illicit open sea sealing.

The final act of the 62d Congress is not less inimical to the welfare of the herd. This was to cut from the Sundry Civil Bill the appropriation for the maintenance of the government force of agents on the fur seal islands, reducing this force to a single care-taker for each island. This is in effect a notice that we have weakened the land defenses of the herd. It is an invitation to the lawless element, largely present among the pelagic sealers, to raid the islands and attack the herd upon its breeding haunts. The natives on the islands are effective defenders only under intelligent and courageous direction. One man can not guard twenty-five miles of shore, for the most part difficult of access through absence of roads and means of transportation. It will not be forgotten that in 1906 Japanese sealers landed upon the rookeries in spite of the active revenue patrol, and were only prevented from inflicting heavy damage upon the herd by the prompt and courageous defense of the resident agents and the natives, a dozen or more of the raiders being killed before the attacks were finally warded off. Reduced to a single care-taker on each island—they are forty miles apart—the island force can make no adequate defense.

The property interests thus being trifled with are of great value, capable of yielding a land catch in 1913 worth not less than \$400,000, and this income will grow steadily. To maintain the herd requires protection for its breeding stock on the high seas and upon the breeding grounds. The treaty of July 7, 1911, guarantees the first, the island guards, the second. It is the duty of the 63d Congress to repeal the provision of the law of August 24, 1912, suspending land sealing, and to restore to the appropriation bills the sum necessary to maintain intact the force for island defense.

Respectfully submitted,

DAVID STARR JORDAN, *Commissioner in Charge of Investigations, 1896-7.*

GEORGE ARCHIBALD CLARK, *Secretary of Commission, 1896-7, Special Investigator 1909 and 1912.*

#### THE EUGENICS RECORD OFFICE

THE Eugenics Record Office, which was established at Cold Spring Harbor, Long Island, in October, 1910, by Mrs. E. H. Harriman and which has ever since been active in this field, with the additional assistance of Mr.

John D. Rockefeller and others, has recently entered upon a new stage of its development. A board of scientific directors has been organized, comprising Dr. Alexander Graham Bell, chairman; Dr. William H. Welch, professor of pathology, Johns Hopkins University, vice-chairman; Professor Irving Fisher, Yale University; Professor Lewellys F. Barker, of the Johns Hopkins University; Professor E. E. Southard, of Harvard University and director of the Psychopathic Hospital, Boston, and Dr. C. B. Davenport, secretary of the board and resident director. The board met at Cold Spring Harbor on March 21, and organized its work. The aim of the Eugenics Record Office was defined to be as follows. First, to promote researches in eugenics that shall be of utility to the human race. This part of the program includes: the study of America's most effective blood lines; and the methods of securing the preponderance and relative increase of the best strains; the study of the origin of and the best methods of restricting the strains that produce the defective and delinquent classes of the community; the study of the method of inheritance of particular traits; the study of the consequences of the marriages of close kin; the study of miscegenation in the United States; the study, both in this country and abroad, of the family histories of permanent immigrants. Second, to publish the results of these researches. Third, to provide a fireproof building for the preservation of eugenical records, including genealogical works and town-histories. Fourth, to provide an administrative office and staff to carry out the work. The fireproof building that is to form the new home of the office is being rapidly pushed to completion.

The board of scientific directors of the Eugenics Record Office will meet each spring at Cold Spring Harbor to consider the projects most worthy of support during the ensuing year, which begins October first, and it will meet again in November to receive a report of the work of the office in the preceding fiscal year. The resident director has general charge of the plant and its operations and is authorized to ask for and receive, in the name

of the board, funds to carry on the work of the office. The board voted in favor of the organization of a Eugenics Research Association, of which a meeting will be called early in June.

#### THE NATIONAL ACADEMY OF SCIENCES

THE National Academy of Sciences will celebrate the fiftieth anniversary of its foundation at the Smithsonian Institution in Washington April 22-24 inclusive. Following is the preliminary program:

##### *Tuesday, April 22*

9:30 A.M. Business meeting of the Academy in National Museum.

11:00 A.M. Opening Session, National Museum.

Welcome by the President of the Academy.

Addresses:

"The Relation of Science to Higher Education in America," President Arthur T. Hadley of Yale.

"International Cooperation in Research," Dr. Arthur Schuster, Secretary of the Royal Society of London.

3:00 P.M. Address:

"The Earth and Sun as Magnets," Dr. George E. Hale, Director of the Mount Wilson Solar Observatory.

9:00 P.M. Reception by the Secretary and Regents of the Smithsonian Institution to the Members of the Academy and their Guests at the National Museum.

##### *Wednesday, April 23*

10:30 A.M. Morning Session.

Addresses:

"On the Material Basis of Heredity," Dr. Theodor Boveri, University of Würzburg.

"The Structure of the Universe," Dr. J. C. Kapteyn, Director of the Astronomical Laboratory, University of Groningen.

3:30 P.M. Reception at the White House and Presentation of Medals by the President of the United States.

9:00 P.M. Reception by the Trustees of the Carnegie Institution of Washington to the Members of the Academy and Guests.

##### *Thursday, April 24*

9:00 A.M. Meeting of the Council at the National Museum.

- 9:30 A.M. Business meeting of the Academy at the National Museum.
- 10:00 A.M. During the business meeting of the Academy, opportunity will be given to guests to visit the scientific bureaus and laboratories of Washington. Automobiles will be provided.
- 2:00 P.M. Excursion to the Home of Washington at Mount Vernon by the U. S. Despatch Boat *Dolphin* (by courtesy of the Secretary of the Navy).
- 8:00 P.M. Dinner at the New Willard Hotel.

#### SCIENTIFIC NOTES AND NEWS

THE Bruce medal of the Astronomical Society of the Pacific has been awarded to Professor J. C. Kapteyn, of Groningen, for his work on the proper motions of the stars.

It is reported that Professor Czerny, of Heidelberg, will give up next year the direction of the institute for cancer research, which was founded by him.

DEAN RUSSELL H. CHITTENDEN, of the Sheffield Scientific School at Yale, is recovering from the effects of a recent operation, but he will be unable to resume his duties for the remainder of the academic year.

By action of the board of regents of the University of Michigan, the name of the Museum of Natural History has been changed to the Museum of Zoology, and Professor Alexander G. Ruthven has been promoted from the position of head curator to that of director.

DR. ELIZABETH REBECCA LAIRD, Ph.D. (Bryn Mawr, '01), professor of physics at Mount Holyoke College, has been awarded the Sarah Berliner Research Fellowship.

THE Yale corporation has voted to appoint Professors Pirsson, Barrell, Lull, Irving and Schuchert as the university's representatives to the twelfth International Geological Congress, to be held in Canada this coming August.

PROFESSORS A. G. CHRISTIE, R. C. Disque and H. J. Torkelson, of the college of engineering of the University of Wisconsin, will accompany the American Society of Mechanical Engineers on their trip to Europe this summer.

PROFESSOR M. M. METCALF, head of the department of zoology, at Oberlin, has been granted leave of absence for the second semester for travel and scientific research in California. His classes are being continued by Assistant Professors Jones and Buddington.

DR. R. M. ANDERSON has been appointed assistant in the department of mammalogy of the American Museum of Natural History. Dr. Anderson will accompany the Stefánsson expedition to the Arctic as zoologist and second in command.

THE little power schooner *Polar Bear* sailed for Bering Sea, on April 3, with a party who will make a study of animal and bird life in northern waters. In the party are Mr. Dunbar Lockwood, of Boston; Mr. Samuel Mixer, of Boston, representing the Smithsonian Institution; Mr. W. Sprague Brooks, of Milton, Mass., representing the Museum of Comparative Zoology at Harvard, and Dr. Joseph Dixon, of Berkeley, Cal., representing the Museum of Comparative Zoology at the University of California. The cruise will last six months.

ALFRED VIVIAN, professor of agricultural chemistry, Ohio State University, is making a tour of the world, and is now in India. Professor Vivian will deliver a course of lectures on soil fertility at the agricultural school at Allahabad.

SIR WILLIAM OSLER, regius professor of medicine at Oxford University and delegate of the Oxford University Press, will give an illustrated lecture on "The Oxford University Press," at Harvard University, April 29.

THE Weir Mitchell lecture before the College of Physicians of Philadelphia was delivered on Friday evening, April 4, by Dr. H. P. Armsby, director of the Institute of Animal Nutrition of the Pennsylvania State College, on the subject, "Animal Calorimeters and the Study of Nutrition."

ON April 2, Professor W. B. Cannon, of the Harvard Medical School, addressed the Rush Medical Society and the undergraduates of the medical school of the University of Pennsylv-

vania on "Some Recent Studies on the Bodily Effects of Fear and Rage."

DR. H. C. MILLER, professor of physics, Case School of Applied Science, lectured under the auspices of the Ohio State University chapter of the Sigma Xi Society on March 7, on the topic "Photographing and Analyzing of Sound Waves." The lecture was accompanied with illustrations.

DR. RAYMOND PEARL, of the Maine Agricultural Experiment Station, gave a series of three lectures on genetics at the Ontario Agricultural College, Guelph, Canada, on March 25 and 26.

ARTHUR H. BLANCHARD, professor of highway engineering in Columbia University, on March 31, delivered an illustrated lecture on "Highway Engineering in Europe and America" before the Brooklyn Institute of Arts and Sciences.

DR. A. C. EYCLESHYMER, of St. Louis University, lectured on March 30 at the University of Illinois on "Growing Old and Attempts to Prevent It." It was one of a series on public health given by authorities in various branches of medicine.

PROFESSOR GEORGE GRANT MACCURDY, of Yale University, recently completed a lecture tour of two weeks in the middle west, the subject being "Ancient Man, His Environment and His Art." He spoke at the Art Museum, Toledo; at Alma College, Michigan; at the Field Museum of Natural History, Chicago; at the University of Missouri, Columbia, and before the Anthropological Society of Washington; also for the Archeological Institute of America at St. Louis, Kansas City, Topeka, Cedar Rapids and Davenport.

PROFESSOR ROBERT WOODWORTH PRENTISS, who had held the chair of mathematics and astronomy in Rutgers College since 1891, died on April 5 at the age of fifty-six years.

DR. GEORGE MCCLELLAN, a Philadelphia surgeon, known for his researches in anatomy, died on March 29, aged sixty-four years.

DR. ADOLF SLABY, professor of electrotechnics in the Berlin Technical School and the University of Berlin, known to the general

public for his contributions to wireless telegraphy, has died at the age of sixty-four years.

At a meeting of the executive committee of the New York Zoological Society held on February 24, Mr. Niles presented a report with reference to charges against Dr. Charles H. Townsend contained in a report of a majority of the committee of the house of representatives on the expenditures in the Department of Commerce and Labor. After reading and careful consideration of Mr. Niles's report, the executive committee passed the following resolutions:

*Resolved*, That after a full examination of the proceedings of the House Committee on Expenditures in the Department of Commerce and Labor, and of the report submitted by the minority of the said committee by which it appears that the said committee has never held a single meeting for the purpose of considering the evidence, and that the report made by the chairman was never submitted to the committee for its consideration, and that in the opinion of the minority the report had never been approved by a majority of the committee, that it is the unanimous opinion of the Executive Committee that the honesty and integrity of Dr. Charles H. Townsend have not been impugned in any way; that the recommendations of said Congressional Committee are in no wise justified by the evidence taken by the committee; that the report of the majority of the committee is drawn without any reference to the facts in regard to Dr. Townsend's connection with the matter, and that the attack upon him is unjustifiable, malicious and untruthful, and further

*Resolved*, That the Executive Committee of the New York Zoological Society does unanimously approve and endorse the report upon the subject prepared by Mr. Niles and the conclusions contained therein.

MADISON GRANT, *Chairman*

LISPENARD STEWART

THE announcement of the twenty-sixth session of the Marine Biological Laboratory, Woods Hole, Mass., has been issued. The im-

portance of the work there accomplished can be seen from the list of the staff, which is as follows:

*Investigation in Zoology and Embryology:* Gary N. Calkins, professor of protozoology, Columbia University; E. G. Conklin, professor of zoology, Princeton University; Gilman A. Drew, assistant director, Marine Biological Laboratory; George Lefevre, professor of zoology, University of Missouri; Frank R. Lillie, professor of embryology, University of Chicago; T. H. Morgan, professor of experimental zoology, Columbia University; E. B. Wilson, professor of zoology, Columbia University.

*Instruction in Zoology:* Caswell Grave, associate professor of zoology, Johns Hopkins University; George A. Baitzell, dean and professor of biology, Central College; Raymond Binford, professor of biology, Guilford College; J. K. Breitenbecker, fellow in zoology, University of Chicago; E. J. Lund, Bruce fellow in zoology, Johns Hopkins University; T. S. Painter, graduate student of zoology, Yale University.

*Instruction in Embryology:* Gilman A. Drew, assistant director, Marine Biological Laboratory; Lorande L. Woodruff, assistant professor of biology, Yale University; A. L. Treadwell, professor of biology, Vassar College; Robert A. Budington, associate professor of zoology, Oberlin College.

*Physiology:* Albert P. Mathews, professor of physiological chemistry, University of Chicago; R. S. Lillie, assistant professor of experimental biology, University of Pennsylvania; Harold C. Bradley, assistant professor of physiological chemistry, University of Wisconsin.

*Botany:* George T. Moore, Engelmann professor of botany, Washington University; George R. Lyman, assistant professor of botany, Dartmouth College; B. M. Duggar, professor of plant physiology, Washington University; Ivey F. Lewis, assistant professor of botany, University of Wisconsin; W. J. Robbins, assistant in plant physiology, Cornell University; R. H. Colley, instructor in botany, Dartmouth College; A. R. Davis, Lockland research fellow, Shaw School of Botany.

*Philosophical Aspects of Biology:* Edward G. Spaulding, assistant professor of philosophy, Princeton University.

The twenty-fourth session of the Biological Laboratory of the Brooklyn Institute of Arts and Sciences located at Cold Spring Harbor, New York, will be held during six weeks, be-

ginning Wednesday, June 25. Investigators may make arrangements for using the laboratory at other times of the year but board at the laboratory will not be guaranteed before June 23 nor after August 9. The instruction offered this year consists of the following courses: field zoology by Professor Herbert E. Walter, of Brown University, Dr. A. H. Melander, professor of entomology at the University of Washington, and Dr. C. B. Davenport. A course in bird study will be given by Mrs. Alice Hall Walter, and by Dr. C. E. Ehinger, of the Pennsylvania State Normal School. Comparative anatomy, by Professor Henry S. Pratt, of Haverford College, and Dr. David D. Whitney, of Wesleyan University. Animal bionomics and evolution by Dr. Davenport. Cryptogamic botany by Dr. Harlan H. York, of Brown University, and Dr. W. E. Maneval, of Randolph-Macon College. Plant geography and ecology, by Professor John W. Harshberger, of the University of Pennsylvania. Those who wish to carry on investigation at the laboratory are invited to correspond with one of the above-named instructors. As in the preceding three years a training course for field workers in eugenics, strictly limited in attendance, is offered by Dr. Davenport and Mr. H. H. Laughlin. The announcement of the laboratory for the coming summer may be obtained by addressing the director, Dr. C. B. Davenport, Cold Spring Harbor, Long Island, N. Y.

A STATION for instruction and research in biology will be maintained by the University of Michigan, for the fifth season, as a part of its regular summer session, during the eight weeks from July 1 to August 22. The station is located near the Bogardus Engineering Camp of the university on a tract of about 1,666 acres of land owned by the university and stretching from Douglas Lake to Burt Lake in Cheboygan County, Michigan, 17 miles south of the Straits of Mackinac. The instructors will include: Henry Allan Gleason, Ph.D., assistant professor of botany in the University of Michigan, acting director of the Biological Station; Frank Smith, A.M., associate professor of zoology in the Univer-

sity of Illinois, assistant professor of zoology; Max Mapes Ellis, Ph.D., instructor in biology in the University of Colorado, instructor in zoology; Harry Nichols Whitford, Ph.D., instructor in botany, and Paul Smith Welch, A.M., fellow in zoology in the University of Illinois, instructor in entomology.

THE American Museum of Natural History, New York, has adopted a pension plan which went into effect on March 1. It is said to be the first instance in this country of a museum of sciences originating a pension system for the benefit of its employees. The idea was suggested to President Osborn after an investigation of the pension plans in operation in Europe. The plan is a contributory system, three per cent. of the annual salaries being paid to the fund by the employees and a like amount by the corporation. The plan provides: (1) Pensions—Six classes of pensions according to length of service and age, the pensions varying from twenty-five to fifty per cent. of the average salary of the last three years. (2) Health Insurance—Gratuity to the employee in case he is totally disabled through illness, or his position is abolished. (3) Life Insurance—Gratuity to a beneficiary, in the event of the death of the employee, and under certain conditions in the event of the death of a pensioner. (4) For the return of the employee's contribution with simple interest at three per cent. in case the employee leaves the service of the museum before he is eligible for a pension.

THE U. S. Civil Service Commission announces an open competitive examination on May 12 for irrigation managers and assistants to fill vacancies in the position of irrigation manager at salaries ranging from \$1,800 to \$2,500 a year, and vacancies in the position of assistant manager at salaries ranging from \$1,500 to \$2,000 a year, in the Reclamation Service, the salaries being dependent upon the size of the project and individual qualifications.

A LONG summer trip is being planned for advanced geological students in Sheffield Scientific School of Yale University who are

ready to complete their field work in geological surveying. For the past two summers, this work has been carried on in the region about Natural Bridge, Virginia; this year the field course, which will cover the six weeks from June 25 to August 6, will be carried on in the Spearfish Quadrangle, near Deadwood, South Dakota, in the heart of the Black Hills.

A CABLEGRAM to the New York *Times* states that the Atlantic transport steamship *Minneapolis* is carrying to America a consignment of about 600 British song birds for the great aviary in Michigan owned by Mr. Henry Ford, the automobile manufacturer. The aviary consists of about ten acres of land inclosed and covered with netting and is said to be the largest in the world. The consignment includes 120 larks, 120 linnets, 70 chaffinches, 100 greenfinches, 20 yellowhammers, 12 bullfinches, 40 blackbirds and 12 jays.

#### UNIVERSITY AND EDUCATIONAL NEWS

THE legislature of Kansas has appropriated \$1,226,000 for the University of Kansas for the next biennium. The legislature refused all requests for new buildings except one for the medical school at Rosedale. The appropriation for maintenance is about \$200,000 more than has been granted for any previous biennium for that purpose.

THE total appropriations for special purposes of the Ohio State University carried by the appropriation measure now before the legislature, amount to \$371,730. Two new buildings are provided for and half of the necessary cost appropriated, the balance to be appropriated next year. These buildings will be for the departments of zoology and botany, and the departments of horticulture and forestry. In addition to the special appropriations, the state levy will provide \$400,000 for the general expenses of the university.

AN endowment fund of \$1,000,000 has been subscribed for Goucher College, Baltimore.

HARVARD UNIVERSITY has received from the estate of Mrs. Sarah A. Matchett, \$150,000 on account of her bequest, to be held as a special

fund to be called the "Matchett Fund," the income of which is to be used for the general purposes of the college.

THE Catholic University, Washington, D. C., is to have three new buildings—two laboratories and a main dining-hall, which will seat 1,000. One building, the chemical laboratory, is to cost \$300,000. The second laboratory building will house the departments of physics and mechanical engineering.

GOVERNOR SPRY, of Utah, has approved a bill recently passed by the legislature creating a department of metallurgical research in the state school of mines, the engineering school of the University of Utah. The new department will be in charge of a director who will be given from four to six young mining engineers and metallurgists as assistants. He will have no teaching whatever to do, but will devote his entire time to research work.

VERY radical changes are in progress in the chemical laboratory of the Rensselaer Polytechnic Institute. A new and larger lecture room is being built on top of the present one, and a new "water" laboratory, capable of accommodating sixty students, is under construction on the second floor. This additional laboratory will be very completely equipped for the analysis of water and sewage and every facility will be provided for undertaking such work from the chemical, bacteriological and microscopical standpoints. The quantitative and organic laboratories will be greatly extended, reequipped and furnished with conveniences of recent type, including glass shelving, enlarged hoods and individual arrangements for blast and suction on the desks.

THERE is pending in the Texas legislature a bill providing for the removal of the State Agricultural and Mechanical College from its present location near Bryan to Austin and its merging with the State University.

THE college of education of the Ohio State University will conduct the educational survey of Ohio, which was provided for by a recent act of the legislature. The purpose of this survey is to secure concise information

concerning the condition of all educational interests of the state. Upon this information future legislation on educational matters will be based. Dean W. W. Boyd, of the college, will have personal supervision over the survey, which will be started at once.

THE Prussian ministry of education (Kultusministerium) has established a bureau of school information (Kgl. Preuss. Auskunftsstelle für Schulwesen) which was opened on April 1, 1913. Dr. Kullnick has been placed in charge of the bureau and will publish an annual year-book under the title of "Jahrbuch der Königlich Preussischen Auskunftsstelle für Schulwesen." The first issue will appear in November of this year and will include all manner of information concerning school matters, such as is not readily accessible in other official or non-official publications. Each volume will contain at least 320 pages. Persons who are desirous of securing information about German schools or school systems are referred to the new bureau, which will be ready at all times to answer any questions concerning these matters.

THE income of the Theresa Sessel fund given to Yale University for promoting original research in biological studies, will, for the present, be used in establishing two research fellowships, to be awarded on the recommendation of a standing committee composed of the chairman of the departments of physiology, zoology and botany, in consultation with the dean of the graduate school. In making the award, preference will be given to graduates of Yale or other universities, who have already obtained their doctorate and who have demonstrated by their work fitness to carry on successfully original research work of a high order. The fellowships will be of the value of \$1,000.

FREDERICK SHELDON traveling fellowships for 1913-14 have been awarded in the sciences at Harvard University as follows:

Donald Clinton Barton, for research in geology in Europe and Egypt during the summer of 1913.  
Sidney Fay Blake, for research in botany in Europe.

Elmer Keiser Bolton, for research in chemistry at Berlin.

Richard Maurice Elliott, for research in psychology, particularly in the psychophysics of handwriting, at Berlin and in the various psychological laboratories of Germany.

Harvey Cornelius Hayes, for travel in the United States, between September and February, for the purpose of observing the manufacture of alloys.

Sidney Isaac Kornhauser, for research in zoology at Würzburg and at the Naples Zoological Station.

Edward Hale Parry, for travel in the mining districts of the United States during the summer of 1913.

Joseph Slepian, for research in mathematics in Europe.

Paul Dudley White, for research in pharmacology at London and Strasburg.

PROFESSOR ERNEST J. BERG, of the department of electrical engineering of the University of Illinois since 1909, has resigned that position to return to a similar position at his alma mater, Union University, at Schenectady, N. Y., and also to become consulting engineer of the General Electric Company of that city.

PROFESSOR R. W. THATCHER, director of the Washington Agricultural Experiment Station and head of the department of agriculture of Washington State College, has been elected professor of agricultural chemistry and soils in the University of Minnesota, the appointment becoming effective on May 1.

#### DISCUSSION AND CORRESPONDENCE

##### ELECTROMAGNETIC INDUCTION AND RELATIVITY

TO THE EDITOR OF SCIENCE: In the last number of SCIENCE (March 14) Professor A. L. Kimball expresses the opinion that my recent experiments on electromagnetic induction are "not so definitely in contradiction to the principle of relativity as may appear at first sight," basing his conclusion on the fact that in certain cases the indication of a measuring instrument depends upon the manner in which it is connected to the apparatus under test.

This is a very important point, but it is naturally one which I had not failed to consider with great care. That no fallacy was made in reaching my conclusion will be evident, I think, from what follows.

*Case I.*—In my own recent experiments the cylindrical condenser, with its armatures *A* and *B* connected together by a wire *C*, remained at rest while the agent producing the magnetic field, whose direction was parallel to the common axis of the two cylinders, was rotated. The short-circuit by the wire *C* was then interrupted, *leaving the inner conductor B completely insulated. After the rotation was stopped and the field annulled, B was tested for charge by connection to an electrometer. No charge was detected.*

*Case II.*—Now imagine the condenser, together with its short-circuiting wire *C*, to rotate while the agent producing the magnetic field remains fixed to the earth. If the wire *C* is now interrupted, *leaving B completely insulated from A*, and if the condenser is then brought to rest and the field annulled, the cylinder *B*, *tested exactly as in Case I., will be found charged.* While the experiment in this form has not been made, the result given is an *immediate and necessary consequence* of the experiments by Faraday and others referred to in my earlier article. For no one will contend that in this case the seat of the motional electromotive force is elsewhere than in the wire *C* and in the dielectric, if any, entrained by the conductors in their motion. Moreover, that the ether is not entrained, and that the entrainment of any air would produce no appreciable effect, are facts which follow from some of the experiments (those on insulators) already referred to. In addition to these considerations only one assumption is necessary to the argument, viz., the assumption that an electric charge of one sign on an insulated conductor is not altered by being brought to rest from a state of motion.

Thus the condenser is actually charged in one case and not charged in the other, the relative motion in the two cases being exactly the same. If complete relativity existed, the condenser, tested in the way described, would be

found to have the same charge in the two cases.

In connection with Professor Kimball's remarks it is of interest to consider also the behavior of two electrometers  $E$  and  $E'$ , one of them,  $E$ , fixed within the condenser with its terminals rigidly connected to the armatures  $A$  and  $B$ , and the other,  $E'$ , fixed to the magnet, with terminals sliding on  $A$  and  $B$ . In Case II.  $E'$  indicates a voltage equal to the motional electromotive force in the wire  $C$ , and  $E$  gives no deflection—*not because the condenser is uncharged, but because the motional electromotive force in the electrometer and its leads just balances the voltage in the electric field produced between  $A$  and  $B$  by the motional electromotive force in the wire  $C$ .* In Case I.  $E$  again gives no deflection, *there being now no electric field between the armatures and no charge at all on the armatures;* and  $E'$  gives the same deflection as before—but whether for the same reason or not is still an open question. It is apparently because Professor Kimball was considering these ambiguous electrometer indications instead of the actual charges on the cylinders that he was led to his conclusion. S. J. BARNETT

THE OHIO STATE UNIVERSITY,  
March 18, 1913

#### A LABELING SURFACE FOR LABORATORY GLASSWARE

THE ground-glass circular spot now generally furnished on flasks and beakers made of Jena glass suggested to the writer the desirability of a similar labeling surface for microscopic slides, test tubes and other laboratory glassware. Attempts to use hydrofluoric acid showed that the acid in solution would dissolve the glass but would not etch it. "Diamond Ink" made by Merck and obtained from Eimer and Amend was found to give satisfactory results. "White Acid," obtained from the same firm, produces a less heavily frosted surface, but has been used to dilute the diamond ink when the latter has become unduly thickened. Diamond ink comes in gutta-percha bottles and etches glass immediately upon coming in contact with it. The

hydrofluoric acid, which is apparently one of the constituents, is volatile. When a bottle has been opened, the fluid tends to creep out by capillarity along the salts that have been deposited by evaporation. The bottles, in consequence, should be kept sealed with paraffine when not in use.

In using, a small amount only of the creamy diamond ink is poured into a stender dish which has been previously coated with paraffine. A rubber stopper has been found to be the best means of applying the ink. One end is dipped into the ink and then pressed against the glass to be etched. If the right edge of the stopper is first touched to the glass and the pressure shifted from right to left and reversed, the fluid is evenly distributed and a small amount only is necessary for the even-edged circular spot which results. The etching takes place at once. The surface, however, is covered by a thick deposit of deliquescent salts which must be washed off before the ground-glass surface is ready to receive pencil marks. Ordinary glassware is easily marked by the method outlined, but the Jena glass tested is etched with more or less difficulty and has been ground on an emery wheel.

Adhesive paper labels are impracticable for test tubes or flasks that have to be sterilized with steam or that are kept in a moist atmosphere where they are liable to the attacks of moulds. Wax pencils, or better, indelible copying pencils moistened with alcohol are useful for temporary labels, but do not withstand steam sterilizing and are not permanent when much handled. Marking diamonds and certain silicate inks have the disadvantage of leaving a written label that can not be removed. A label written with lead pencil on an etched or ground-glass surface, however, has the advantage of permanency so far as ordinary laboratory handling is concerned. It is as permanent as pencil marks on paper and, like these, can be removed with a rubber eraser. The pencil marks are not affected by water nor by steam, but may be readily removed by scouring soaps. In cleaning test tubes, it has been found convenient to remove

the labels by rubbing the surface in a moistened groove in a cake of sapolio.

A. F. BLAKESLEE

CARNEGIE STATION FOR  
EXPERIMENTAL EVOLUTION,  
COLD SPRING HARBOR, N. Y.

MOST IS—WHAT?

TO THE EDITOR OF SCIENCE: Since the natural sciences came into their inheritance, about thirty years ago, it has been quite the orthodox thing with the "humanists" to demonstrate the inherent disability of these subjects to impart "culture" by satirically deriding the English of embryonic doctoral dissertations. Judge, therefore, of the shock to my esthetic sensibilities occasioned by this sentence, which stands on page 61 in the issue of SCIENCE for January 10: "*most of the brotherhood of teachers of English is in the same state,*" where the adjective-noun *most*, having the plural form because clearly referring to number and not quantity, is made the subject of a verb in the singular number. This communication appears to have been written by a professor of English and, presumably, a humanist.

F. W. MARTIN

#### SCIENTIFIC BOOKS

##### *Methods of Measuring Electrical Resistance.*

By EDWIN F. NORTHRUP, Ph.D. New York, McGraw-Hill Book Company. 1912. Pp. xiii + 389. Price \$4.00.

The measurement of electrical resistance is of interest not only to the physicists but to engineers and others engaged in scientific, technical and commercial work. The methods used are described in various technical and scientific papers and in text-books on electrical measurements. But only a few of these are described in any one place, if we except Price's book written about twenty years ago. The author "has selected for presentation all those methods which in his judgment are useful, for commercial tests and measurements, for purposes of instruction in educational institutions and for application in technical and research laboratories." So we have collected

in one book a large number of methods covering practically the entire field of electrical resistance measurements.

The first part of the book is of an introductory character and better than any other shows the wide experience and sound judgment of the author in matters pertaining to electrical measurements. Particularly good are his comments on accuracy and method and few there are, of those who make electrical measurements, who could not read with profit the first six pages. Then follows a discussion of errors and estimation of the accuracy obtainable by deflection methods. The way an error in measurement may affect the result desired is clearly shown, but no effort is made to arrive at the probable accuracy by the means of the theory of probabilities.

Deflection methods are taken up first. Various voltmeter methods and voltmeter and ammeter methods are considered very fully. Then follows a discussion of null methods and of these the differential galvanometer methods are considered first. In this connection no mention is made of the Kohlrausch method, which is generally considered to be by far the best and by some to be the only differential galvanometer method suitable for use in the precise comparison of resistances.

In the discussion of the Wheatstone bridge methods the Carey Foster method receives the fullest consideration. Six kinds of measurements are listed for which it is stated that this method "is especially useful." For one of these measurements deflection methods give all that is usually desired. When a higher accuracy is necessary it is easily obtained by the simplest kind of a bridge. Another is of interest only to the manufacturer in the adjustment of resistance coils. The other four can, provided a substitution method is used, be made much better with a simple bridge costing not more than half as much as the Carey Foster bridge.

In the discussion concerning Wheatstone bridges various arrangements of ratio and rheostat coils, including the author's four-coil decade, are considered; the author's special bridge for reading directly the per cent. error

in the adjustment of resistance coils is described; and valuable suggestions given in regard to the selection and use of bridges and auxiliary apparatus.

Methods and apparatus for measuring low resistances and calculation of conductivities are treated fully, as are also the methods and apparatus for measuring high resistance and the insulation resistance of cables. A chapter is devoted to the measurement of resistance-containing electromotive forces, insulation resistance with power on, resistances of batteries and electrolytes. Some of the methods described here were developed by the author.

A description is given of the author's dynamometer method for measuring the resistance of an inductive conductor to alternating current. A non-inductive resistance is adjusted so that the power dissipated in it is equal to the power dissipated in the inductive resistance as shown by the dynamometer. The two resistances being in series carry the same current and therefore have the same resistance.

The methods and apparatus used in locating faults are fully described. Here again some of the methods were developed by the author.

One of the important applications of electrical methods to other physical measurements is that of the measurement of temperature or temperature changes by means of the resistance thermometer. Apparatus intended for use between 0 and 100° C. should be capable of indicating small changes in temperature with certainty to .001° C. This means that changes in the resistance of the thermometer must be measured to better than  $3\frac{1}{2}$  parts per million of its total resistance. Therefore, careful attention must be given to the compensation for the various changes in resistance of leads, changes in resistance of contacts, etc. As the resistance thermometer must have a small heat capacity to follow temperature changes quickly and as it has a large temperature coefficient, the power supplied by the test current must be kept very small in comparison with that which might be used in the measurement of ordinary manganin coils of the same resistance. For this reason

a sensitive galvanometer is required and care must be taken to correct for the thermo-electromotive forces, practically always large enough to introduce an error of a few thousandths of a degree. In discussing resistance thermometers the author apparently fails to appreciate the importance of some of these matters, for the arrangement which he is inclined to believe "offers more advantages than any other" if used in ordinary calorimetric work should hardly be expected to give satisfactory results. Much difficulty would be experienced in an accurate compensation for the changes in the resistance of the galvanometer windings. Then unless the galvanometer were more sensitive than the one which the author states "is amply sensitive for the purpose" we should hardly expect an accuracy better than that obtainable with a good mercury in glass thermometer. The galvanometer should be at least a hundred and preferably over a thousand times more sensitive.

Under the heading "Instruments Used for Measuring Resistances" the reader will find much in the nature of good advice both to the intending purchaser and user of such apparatus.

In the consideration of deflection instruments and galvanometers attention is called to what constitutes desirable qualities in ammeters, voltmeters, pointer galvanometers and mirror galvanometers. Instruments designed by the author and constructed under his supervision are described. The author's method of comparing galvanometers is given fully, together with a table giving constants of sixteen galvanometers. In this connection no reference is made to the important papers of White and Jaeger.

In an appendix a few mathematical formulas and tables, and physical constants are given.

Practically the entire field of resistance measurements is covered and most of the methods used are well described. However it is assumed that a .01 or even a .1 per cent. is a high accuracy and sufficient for all but very exceptional cases. The book will be welcomed by almost every one who uses resistance appa-

ratus and galvanometers—by the men engaged in commercial testing because of the description of the methods suited to the needs and the good advice given in regard to the selection of apparatus for different kinds of work; by the instructor in our educational institutions because it constitutes a valuable reference book for him and his students; by the specialist because to him the author succeeds in a marked degree in giving the benefit of his wide experience in the design, construction, and use of resistance and electrical measuring apparatus.

BUREAU OF STANDARDS

*Metabolic Water: Its Production and Rôle in Vital Phenomena.* By S. M. BARCOCK. Research Bulletin No. 22, The University of Wisconsin Agricultural Experiment Station, March, 1912.

The purpose of the author in this paper of 181 pages is to show that metabolic water is not only produced in considerable quantity from the organic constituents of the foods and tissues of plants and animals by oxidation and hydration, but also that water from such sources exercises a different function from imbibed water, and that in very many cases is essential to the growth and continued life of the organism in question. The studies were conducted with corn plants for the most part. The studies from the zoological standpoint were not so extensive. The animals used were clothes moth (*Tinea pellionella*); bee moth (*Galleria mellonella*); pea weevil (*Bruchus quadri-maculatus*); flour beetle (*Tribolium confusum* and *Ephesia kuehniella*).

The scope of the study is indicated by the following selected headings taken from the table of contents: Sources of metabolic water (respiration, etc.); metabolic water in seeds; germination phenomena; metabolic water in mature plants; composition of plant tissues; development of hydrolytic ferments in seeds; imbibition; reserve nutrients in plants; water content of green and ripe fruits; intramolecular respiration; water produced in animal metabolism; water requirements of animals.

The author seems to have shown in a rather convincing manner that metabolic water plays an immensely important rôle in the life of both plants and animals. The paper contains many facts collected together in a form such that they should be interesting to every plant physiologist.

RAYMOND J. POOL

THE UNIVERSITY OF NEBRASKA

*Fresh Air and How to Use It.* By THOMAS SPEES CARRINGTON, M.D. The National Association for the Study and Prevention of Tuberculosis, 1912.

This little book is timely and well conceived. It finds an enormous audience prepared to welcome it through sanitary precepts from press and platform for many years. Therefore the responsibility of the author is somewhat unique. One could wish that the execution of the work might deserve unqualified praise. Fortunately it should be easy for the author to correct such matters as call for adverse criticism.

We believe that it is better to be true than to be convincing. Our author's introduction needs rewriting, for it is founded on the old conception that the prime danger from "bad air" lies in its chemical composition. His effort to put a known good thing on a scientific basis suggests the abominable method of instruction by which many popular school physiologies have been perverted for the purpose of lambasting narcotic drugs and alcohol.

In spite of a vast amount of research we are still none too well informed as to the essential physiological relations of "pure" air.

But it seems to have been demonstrated that all morbid sensations attributable to "foul air" depend wholly upon the effects of combined humidity and heat upon the skin. Moving air—a breeze—accelerates heat loss from the body, stimulates the skin in other ways and brings subjective comfort. Now in nature moving air is found most easily in the open or at least in apartments exposed to the open. Sanitary architects—God save the mark—find their task in evolving intricacies of construction whose design it is to obviate

the sanitary evils of construction. We have known of school rooms heated by the "indirect method" in which the winter air containing but a few grains of moisture to the cubic foot is warmed by passing over steam coils and then delivered to the school room, whose windows are closed by edict, its relative humidity so lowered that the moisture must be actually sucked from the skins and mucous membranes of the defenceless children. This air is chemically pure but physiologically like salt to a raw surface.

The little book under consideration is excellent in the orderly presentation of the various phases of the subject and too much praise can not be given for its profuseness of illustration, one hundred and fifty cuts being devoted to this purpose. The average mind derives a clearer idea of architectural design from a simple figure than from pages of labored description. It is to be hoped that in preparing another edition the author will carefully review his text with the purpose of removing all obscurity. Thus, the legend to Fig. 1, p. 22, reads "When the upper window sash is let down and the shade lowered, a larger amount of fresh air may be obtained by inserting a strip of open mesh netting between the shade and the roller." This is perfectly clear when the mechanism is understood, but it requires an undue mental effort to grasp its meaning. The author was happy in his section devoted to the use of clothing and he might profitably have discussed somewhat more in detail the physiological relations of textures—as, for example, the relative properties of silk, linen-mesh and woolen underwear. One of the most valuable chapters of the book is that which exploits the advantages of the house roof to the seeker after fresh air. It is worth enquiring whether it would not be well to devise a mirror situated so as to reflect the scenes of the street to relieve the monotony of "sitting out."

In the section devoted to the clothes-closet, it would have been well had the author insisted that garments, before being stored away, should be hung in the open air, in sunlight if possible, *with the pockets turned inside out*.

Few things are more difficult than to present a "nature study" which shall be scientifically true while forensically convincing to the lay mind. The practical essentials of fresh-air teaching have been excellently presented in this volume, but we are all too much interested in the subject to tolerate the smallest gnat in the ointment. Modern research suggests that the open air calls upon the autonomic systems of the body for somewhat the same kind of response that physical exercise demands of the skeletal nerves and muscles. We know definitely that in the treatment of tuberculosis, for example, exercise may be healing or deadly according to the state of the patient. The truth may very well be that a prescription of "fresh air" is not so simple, but must in scientific therapeutics be analyzed into its physical components of barometric pressure, motion, humidity, temperature, illumination and electric tension and to all these there must be added the one constant excipient—elixir of joy.

HENRY SEWALL

#### SCIENTIFIC JOURNALS AND ARTICLES

THE March number (volume 19, number 6) of the *Bulletin of the American Mathematical Society* contains the following papers: Report of the nineteenth annual meeting of the society, by F. N. Cole; "The product of two or more groups," by G. A. Miller; "The mathematics of Mahāvīrācārya," by D. E. Smith; "Shorter notices:" Townsend and Goodenough's *First Course in Calculus and Essentials of Calculus*, by N. J. Lennes; Dziobek's *Differential- und Integral-Rechnung* and Hack's *Wahrscheinlichkeitsrechnung*, by G. W. Myers; Brill's *Relativitätssprinzip*, Föpl's *Technische Mechanik*, Volume I., and Orlich's *Theorie der Wechselströme*, by E. B. Wilson; "Notes"; and "New Publications."

THE April number of the *Bulletin* contains: "Some general aspects of modern geometry," by E. J. Wilczynski; "On certain non-linear integral equations," by H. Galajkian; "A theorem on asymptotic series," by V. C. Poor; "On Poincaré's correction to Bruns' theo-

rem," by W. D. MacMillan; "Note on the groups for triple-systems," by L. D. Cummings; review of De Séguier's *Théorie des Groupes de Substitutions*, by G. A. Miller; review of Wilson's *Advanced Calculus*, by W. E. Byerly; review of Prasad's *Differential and Integral Calculus*, by E. B. Wilson; "Shorter notices"; Tannery's *Mémoires scientifiques*, Volume I., by D. E. Smith; Natorp's *Logische Grundlagen der exakten Wissenschaften*, Grelling-Enriques' *Probleme der Wissenschaft*, and Volkmann's *Erkenntnistheoretische Grundzüge der Naturwissenschaften*, by J. W. Young; Pascal's *Repertorium der höheren Mathematik*, second edition, by C. H. Sisam; Love's *Differential and integral calculus*, by Arnold Dresden; "Notes"; and "New Publications."

*THE INFLUENCE OF VARIOUS EDUCATIONAL INSTITUTIONS UPON THE DEVELOPMENT OF AGRICULTURAL SCIENCE*

EDUCATION in the general field of agricultural science is coming to occupy so large a place in primary, secondary and collegiate instruction, that the development of this field is of almost universal interest among educational workers. Both the subject matter and the pedagogical methods of agricultural science are so new as to be practically the creation of the present generation of research students and educators. It was of interest to the writer, therefore, to ascertain, as fairly as circumstances would permit, the sources for the inspiration and conception of the men who are building up this new science. It occurred to me to ascertain at what institutions of learning the men who were shaping the thought in this field secured their scholastic training, both undergraduate and postgraduate. Each of the leading educational institutions of the world is generally recognized as standing for a certain type of instruction or conception of educational methods. It seemed to be of interest to determine to what proportionate extent the ideals of each such institution are influencing the development of agricultural science.

For this purpose, a study was made of the number of degrees (exclusive of honorary degrees) granted by each institution to persons who are, or who have been during the past five years, members of the Society for the Promotion of Agricultural Science. This society does not, of course, include every person who is actively engaged in this field of work. But its membership does include a very large proportion of the leaders of this movement in America, and is probably closely representative of the scholastic training which such leadership has received.

DEGREES GRANTED BY VARIOUS INSTITUTIONS TO MEMBERS OF THE SOCIETY FOR PROMOTION OF AGRICULTURAL SCIENCE

	Bachelors	Masters	Doctors
Michigan Agricultural College.....	21	15	2
Cornell.....	9	9	7
Iowa State College.....	9	9	0
Harvard.....	4	4	5
University of Wisconsin.....	3	3	4
Mass. Agricultural College.....	9	1	0

Kansas Agricultural College.....	2	2	0
Colorado Agricultural College.....	2	2	0
So. Dakota Agricultural College.....	3	1	0
University of Washington.....	2	2	0
European universities.....	2	0	12

The proportionate distribution of the degrees received by these men among the several institutions does not necessarily indicate the relative esteem in which these institutions are now held by men of agricultural science as schools for training in this field. It is probably a more accurate measure of the opportunities which were available at the time when these men were seeking their scholastic training. Again, the present standards and ideals of these institutions may be quite different, with many of these men now on their facul-

ties, from those which prevailed in the institutions when they were undergraduate or graduate students. But it is believed that the figures given above approximately represent the influence of the several institutions upon the general trend of thought in agricultural science.

Of the 54 other degrees granted to members of this society, not more than three came from any one institution. In these computations no account has been taken of honorary degrees, only those granted for completion of prescribed work having been counted.

It is perhaps of interest to note that the 147 men who have been on the membership roll of this society during the past five years have received 128 bachelor's, 82 master's and 51 doctor's degrees earned by undergraduate and graduate study. While statistics as to the scholastic attainments of workers in other educational fields are not available for comparison, it appears to the writer that the scholastic training and ability of the men who are actively engaged in the promotion of agricultural science is certainly such as to command very high respect.

PULLMAN, WASHINGTON

### SPECIAL ARTICLES

#### THE DISTRIBUTION OF OCCIDENTAL SPIDERS

A PERFECT knowledge of geographic distribution can not be had until we have good collections with good field notes from all important regions and a perfect taxonomy. That time is far distant. Meanwhile we can get some indications from the material at hand. One of the interesting problems concerning the relations between the two continents of the western hemisphere is the part, if any, which the West Indies has played in geographic distribution.

Spiders being carnivorous, and so probably not limited in their distribution by the distribution of special food, and being unable to fly or swim great distances, seem to offer excellent material for such a study. Unfortunately large collections have not been made

and the taxonomy is rather chaotic. Omitting a number of genera either because of indefiniteness of information as to distribution or obvious errors in taxonomy, there still remain in Petrunkevitch's catalogue<sup>1</sup> 764 genera of spiders found in the western hemisphere. The distribution of these is analyzed to some extent in the table. While 119 of these genera are recorded as occurring in both South America and the United States, it is probable that there would be more were it not for the tendency to magnify taxonomic differences when political boundaries are crossed. It is somewhat surprising, in view of the usual notion that insular conditions lead to taxonomic separation, to find that only 14 per cent. of the West Indian genera are not found in neighboring regions, while 60 per cent. of the South American do not occur elsewhere. Even 22 per cent. of the Central American (Mexico being included) genera are not recorded as occurring in the adjacent regions.

*Distribution of Genera of Spiders. Bold-faced type shows actual numbers; ordinary type, percentages.*

<sup>1</sup> A. Petrunkevitch, "A Synonymic Index-catalogue of Spiders of North, Central and South America with all Adjacent Islands," *Bull. Amer. Museum Nat. History*, Vol. XXIX., 1911.

<sup>2</sup> In the sense that they are not recorded from any of the other regions considered here.

Of the 119 genera common to South America and the United States 39 per cent. are recorded also from both Central America and the West Indies, 30 per cent. also from Central America, 6 per cent. also from the West Indies and 25 per cent. from neither. It is probable that the latter percentage will be greatly reduced by further exploration of the intervening regions and by revisions of taxonomy by which either these genera will be split or species from intervening regions will be united with them. However, such distribution is not unusual in other groups and can not be discussed profitably more in detail with this material. The following extreme illustrations from the Linyphiidae may be cited. *Gonatium* with one species in Patagonia, two in northern United States (one of them also in Europe) and one in Greenland; *Gongyli-dium* (closely related to *Gonatium*) with two species in Patagonia (one of them also in Argentina) and three species from Maryland to New York; and *Minyriolus* with one species in Patagonia and one in Massachusetts.

It was noted above that only 6 per cent. of the genera common to South America and the United States are found elsewhere in the West Indies, but not in Central America. Leaving out of the question the fact that these may eventually be found in Central America, it is evident that the West Indies have not been an important highway for the interchange of Arachnid fauna. We should expect the influence it has had to be most apparent in the fauna of our southeastern states, but only one out of 62 genera common to that region and South America is found in the West Indies and not recorded from Central America, while 35 per cent. of them are found in Central America and not recorded from the West Indies. This one genus is *Bolostromus* with one species (*B. fluviatilis*) recorded from Alabama, one (*B. insularis*) from St. Vincent and four from South America.

Therefore, making all allowances for deficiencies in taxonomy, records and my analysis of the records, we must conclude that prac-

tically the only interchange of spiders between the two continents has been by way of Central America.

FRANK E. LUTZ

#### THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

##### SECTION D

PROFESSOR O. P. HOOD, mechanical engineer for the Bureau of Mines, was elected vice-president of the association and chairman of Section D for the next meeting, at Atlanta. Professor A. H. Blanchard, of Columbia University, was elected secretary for five years to succeed G. W. Bissell, whose term expired. G. W. Bissell was elected a member of the council for the Atlanta meeting, and Mr. W. Bowie a member of the sectional committee for five years, *vice* A. H. Blanchard, whose term expired.

The section held meetings on January 2 and 3 for the presentation of papers. Vice-president J. A. Holmes, chairman of the section, presided on January 2, on which date the program was of a general character. Professor A. H. Blanchard presided on January 3 for two sessions devoted to papers on highway engineering. January 4 was assigned as a field or inspection day for those interested in good roads.

Retiring vice-president C. S. Howe, owing to absence on leave from Case School of Applied Science and other duties, did not present an address before the section.

The section is under obligations to the local committee and the authorities of Case School of Applied Science for the very excellent facilities for meetings; to those who, although not members of the association, contributed papers and discussions, and to those of its own membership who responded to requests for papers.

The secretary is indebted to Professor A. H. Blanchard for material assistance in the preparation of the program.

The Cleveland meeting of Section D was very encouraging to those interested, notwithstanding the storm on January 3 materially reduced the attendance.

Abstracts and titles are listed below by groups.

##### MISCELLANEOUS PAPERS AND TITLES

*The Precise Level Net of the United States:* WM.

BOWIE, inspector of geodetic work, Coast and Geodetic Survey, Washington, D. C.

The Coast and Geodetic Survey has recently made an adjustment of the different loops or circuits or leveling forming the precise leveling net of the United States, which will give the most probable values for the elevations of bench marks. The datum used is mean sea level, and it is assumed that the mean levels of the Atlantic, Gulf of Mexico, and Pacific are in the same level surface. Deviations from this condition, if there are any, are not greater than the accumulated errors in a line of leveling joining any two of these bodies of water.

There are 44,720 kilometers (27,790 miles) of leveling, run in two directions, and about 10,700 permanent bench marks involved in the precise leveling. There is now precise leveling in all except seven states in the United States and the net is of such strength that the elevations resulting from the recent adjustment will probably be held as *standard* elevations for an indefinite time. This will be a great benefit to surveyors and engineers who experience great difficulties when the elevations of bench marks are changed or placed on different data. Theoretically, with each new loop added to the level net, new and better values for each bench mark may be obtained by an elaborate adjustment of the net, but the change from the old value would, in nearly all cases, be exceedingly small and insignificant, as far as engineering and surveying needs are concerned. The plan adopted by the Coast and Geodetic Survey is to hold fixed the old leveling and to fit any new sections to it. From time to time adjustments of the net will be made from which to obtain the theoretically best values of the junction points in the net, which will be of scientific interest only, and the resulting elevations would be needed for surveying and engineering purposes.

*The Use of Logarithmic Coordinates in the Laboratory:* D. MOOMAW, assistant professor, applied mechanics and hydraulics, Case School of Applied Science.

Presentation of diagrams, showing, on logarithmic cross-section paper, the method of determining the coefficients and exponents of curves of the second and third degrees, such as represent sometimes the relations between physical quantities in experimental work in the engineering or physics laboratory.

The observed values are plotted on logarithmic paper and the method applied simply and quickly.

*The Michigan Industrial Compensation Act:* G. W.

BISSELL, dean of engineering, Michigan Agricultural College.

The most striking as well as the strongest feature of the law is that, except for farm and domestic help, the defenses of contributory negligence, negligence of fellow servant and assumption of inherent risks, are denied to the employer. The workmen's compensation and employers' liability act has been in operation in this state about two and one half months, and so far the material provisions of the law and the machinery provided for its operation seem to be well adapted to carry out and make effective the general purposes of the statute. It is a well-constructed and workable act in its general features, and should be given a fair trial in its present form before any attempt is made to materially amend it. The general acceptance and approval of the law by a vast majority of the employers of labor in the state, and its approval by workmen generally, constitute persuasive evidence that the act in its present form substantially meets the requirements and performs the functions intended.

*California Electric Furnace Pig Iron:* F. C. LANGENBERG, Athens, Ohio.

A brief account of electric furnace reduction in California and Sweden is given with a comparison of the practices in the two countries. A brief outline is given of the California furnace: (1) description of the furnace and electrical equipment, (2) operation and product of the furnace.

Part Two deals with a microscopic study of pig irons. Two samples of California iron are discussed and their chemical and physical properties predicted by the aid of the microscope. These predictions are confirmed by analyses. The influence of the rate of cooling on the size of the graphic flakes is also shown.

*Present Status of the Gas Turbine Problem:* F.

C. WAGNER, professor of mechanical engineering, Rose Polytechnic Institute.

It seems probable that with the gas turbine, as in the case of the steam turbine, the most profitable field will be in large units, when large volumes can be handled with a relatively small machine. In large installations, also, it would be worth while to install apparatus for saving the heat in the exhaust gases.

Altogether the gas turbine art has made substantial progress during the past year and the outlook for practical development in the near future seems especially favorable.

*Notes on Some Properties of Explosive Mixtures of Air and Gas:* F. H. VOSE, professor of mechanical engineering, Case School of Applied Science.

The paper refers particularly to some experiments performed with explosive mixtures of air and illuminating gas. These experiments were conducted at Washington University, St. Louis, Mo., the gas used being the illuminating gas from the city mains.

The investigation was undertaken to determine the effect of the presence of water vapor on the properties of explosive mixtures, such as pressure ratio resulting from combustion as well as the time increment involved for the completion of combustion.

While the investigation covered a wide range of mixtures, the paper was written to cover a mixture containing 4.75 parts of air to 1 part of gas by volume. This mixture approximates the theoretically best mixture for complete combustion.

Pressure rise was measured by means of the ordinary gas-engine indicator and time records obtained from tuning-fork records on the indicator card. The indicator drum was driven at a constant rate.

Slides made from original cards are shown to indicate the character of the results. Curves were also presented giving the results in graphic form.

When water vapor is present in the ratio of 0.05 parts by weight to the gas mixture a pressure ratio from explosion = 5.5 results; when the quantity of water vapor present represents 0.35 parts by weight the pressure ratio resulting from explosion is only 2.3. The retarding effect on flame propagation is correspondingly great.

*The Manufacturing Organization:* HUGO DIEMER, State College, Pa.

Organization defined, Organization distinct from system and management, To lay out a new organization or to analyze an existing one, Numerical military type, Specialized type, Functionalized type, Staff principle applied to industry, Selecting the type or organization and control to be applied to a given industry, Determining the will of the organization as a whole, Setting forth specific duties, A typical conventional industrial organization, Department of records, Department of materials, Department of plant, equipment and processes, Routing, Scheduling, Motion and time studies, Preparing instruction, instruction cards and instruction sheets, Standardization of equipment, Department of men, Hygiene and efficiency, Psy-

chology and efficiency, Industrial education, Development of loyalty through social and religious activities, Line organization, Progress of an order through an industrial establishment, Carrying into effect the above principles.

*A Further Analysis of the Deflections and Stresses in Reinforced Concrete Floor Slabs Constructed on the Turner Mushroom System:* H. T. EDDY, dean of the graduate school, University of Minnesota.

At the Washington meeting last year the present writer gave an account of his success in developing a rational analysis of this kind of flat slabs. That analysis was based upon the application of the theory of circular plates to this form of construction.

In making such application, it is implicitly assumed that any one of the panels of a slab is supported by surrounding columns in such a symmetrical manner that the central part of a panel carries its loading approximately in the same manner as a circular plate would do when suitably supported at its circumference. This supposition will be nearly exact at points near the center of the panel and less so the greater the distance from the center.

Again the part of the slab at and near a column head in a slab of many continuous panels will have the loading and supports so symmetrically disposed about it that it will act nearly like a circular plate with a central support at the column, at least for points near the column.

While the application of these principles was found to give sufficiently precise values of the central deflections of panels, and of the stresses at the same points, and over the columns, at other points than these the results were not and could not be expected to reproduce the results of tests. It therefore appeared desirable to develop a more closely approximate general theory of the flexure of the reinforced concrete flat slab.

The writer has had unexpected success in developing this general theory from the fundamental differential equation of flexure of slabs, by the help of which its deflections at any points are readily computed, as well as the stresses in reinforcing rods and concrete, notwithstanding the extreme irregularity of distribution of the reinforcement. This last fact requires certain hypotheses in the adaptation of the general solution for a uniform slab to the actual slab, which are proved to be admissible approximations by the agreement of actual tests with numerical computations.

Many interesting and unexpected results appear as part of this investigation whose main conclusions have been already reached. Among these is the fact that the point of maximum stress in steel is midway directly between columns and not at the center of the panel.

It is the intention of the writer to prepare and publish a treatise upon this subject after concluding his investigations upon flat slabs and upon the theory of combined beam and slab floors. These forms of construction have been ordinarily treated by American engineers by applying some form of beam theory to their computations. This has been a fruitful source of bad design and error, because in beam theory the moment of the applied forces is equal to that of the resistance of the beam, whereas in slab theory such an equality does not exist, since these may differ by 100 per cent.

It has been found that slabs are in fact perfectly safe which beam theory would regard as far otherwise. Correct theory is therefore of extreme importance in slab design.

*The Significance of Empirical Tests to the Application of Explosives in Practice:* CLARENCE HALL, U. S. Bureau of Mines, Pittsburgh.

Read by title.

*Sampling Coal Deliveries:* G. S. POPE, Washington, D. C.

Read by title.

*Smoke Prevention in Cleveland:* E. P. ROBERTS, city smoke inspector, Cleveland, Ohio.

A brief account of the routine of city department of smoke inspection and results accomplished at prominent plants, with locomotives and steamships.

When possible plans for boiler settings are reviewed before installation to prevent unnecessary expense to the owner.

Cleveland has noticeably improved in the matter of smoke during the past few years.

Mr. Roberts also exhibited a novel and valuable smoke chart intended to overcome the objections to the Ringelman charts.

#### PAPERS ON HIGHWAY ENGINEERING

*Bond Issues for the Construction of State Highways:* JAS. R. MARKER, state highway commissioner, Columbus, Ohio.

Read by title.

*The Design of Various Types of Highway Bridges from the Standpoint of Modern Traffic:* FRANK H. NEFF, professor of civil engineering, Case School of Applied Science, Cleveland, Ohio.

Subject discussed at length by the author and liberally illustrated with lantern slides.

*Methods of Repairing Cement Concrete Pavements:* FRANK F. ROGERS, deputy commissioner, State Highway Department, Lansing, Mich.

In practise repairs to these pavements are made by two distinct methods, depending on whether the defects are on the surface or extend deeper into the mass. Surface treatment is given by first cleaning the defective places, then filling, or covering them with hot bitumen, preferably refined tar, and coating with sand. This applies to wear at the expansion joints and to cracks caused by natural causes as well as to a pitted condition of the surface, and tends to prevent further deterioration of the places repaired. As a rule, repairs of this kind have to be made annually. In Wayne County, Michigan, the cost of such repairs has been about \$50 a mile. When the defects lie deeper a portion of the concrete is chiseled out, usually to the sub grade, the exposed edges thoroughly cleaned and given a wash coat of neat cement, after which the excavation is filled with the same kind of concrete that was used in the original construction. Repairs of this kind generally prove satisfactory. Bellefontaine, Ohio, reports that repairs on 4,400 square yards of cement concrete pavement laid in 1893 and 1894 have cost only about \$200.

*Relative Advantages of Laying Brick Pavements on Sand Foundations and Cement-Concrete Foundations:* ROBERT HOFFMAN, chief engineer, Department of Public Service, Cleveland, Ohio.

Relative economy of using a sand or concrete foundation for a brick pavement depends upon its first cost, cost of maintenance and life. Accurate data relative to maintenance and effect of traffic is not at hand. Records of cities which show the time that has elapsed between the laying and relaying of a pavement affords the best available evidence upon which to base estimates of relative economy.

In Cleveland, which is chosen as a representative city with reference to brick paving, prices paid per square yard of brick pavement, have varied as follows:

- 5 in. brick laid on natural sand foundation, \$1.18 to \$1.56.
- 5 in. brick on 8 in. sand or gravel ballast foundation, \$1.40 to \$1.97.
- 5 in. brick on 6 in. concrete foundation, \$1.94 to \$2.48.

4 in. brick on 6 in. concrete foundation, \$1.71 to \$2.34.

4 in. brick on 4 in. concrete foundation, \$1.47 to \$1.73.

During the last three years the following average price has been paid.

5 in. brick laid on natural sand foundation, \$1.27 per sq. yd.

5 in. brick on 8 in. sand or gravel foundation, \$1.58 per sq. yd.

4 in. brick laid on 4 in. concrete foundation, \$1.60 per sq. yd.

Average life of five inch brick on sand foundation is taken from the city's experience to be fifteen years. Four-inch brick on sand foundation is assumed as twelve years. From this data it is calculated that four-inch brick can be laid on four-inch concrete as economically as the five-inch on natural sand foundation if the life will be twenty-two years. Four-inch brick can be laid on six-inch concrete as economically as five-inch brick on eight inches of sand or gravel foundation if its life is eighteen years.

It is concluded that when conditions are favorable a five-inch brick laid upon a good natural sand foundation will form the cheapest form of brick pavement, but in all other cases one with a concrete foundation will prove the most economical.

#### *Some Considerations Affecting the Interaction of Motor-vehicle Wheels and Road Surfaces:* DR.

L. I. HEWES, chief, division of economics and maintenance, Office of Public Roads, U. S. Department of Agriculture, Washington, D. C.

In this paper, the author suggests the fundamental work equation

$$(1) \quad \frac{h}{v} = f,$$

where  $h$  is effective horsepower developed at the tires of the motor wheels of an automobile,  $v$  is the velocity, and  $f$  the total resistance. This equation obtains on a level at constant speed and with the air resistance neutralized by a wind current parallel to the velocity of the machine. It is important to determine the nature of the resistance  $f$ , which is in a sense a road coefficient, as it must vary for the same automobile on different roads. The resistance to the motion above described can not be solely due to the action of gravity on the weight of the machine as much as assumption demands a constant resistance for all speeds on the same road. A table is presented showing the relation between effective horsepower, velocity and

resistance of traction. This table was published in *Le Genie Civil*, Vol. LXI, No. 14, p. 276, and exhibits the relation of equation (1). It is the record of tests made in 1912 in Paris on a Berliet truck.

The author discusses two sources of resistance which must be included in the symbol  $f$ . First the resistance which is developed by the motion of the points on the automobile tire not in contact with the ground and which strike small particles with a positive forward velocity. It is pointed out that a point on the periphery of a tire moves in a cycloid and at the instant of contact has zero velocity, whereas points immediately adjacent to the periphery and not in contact with the ground move in rolling curves with velocities having considerable horizontal components which may produce small and continuous shocks, which, owing to the varying magnitude of the velocities in the same vertical cross-section, can produce twisting action upon small particles comparable to the "English" of a billiard ball and thus throw small material to one side of the path. Table of velocities of points at varying vertical distances from the road surface follows. A second source of resistance is described. This resistance is due to the fact that the pneumatic tire which is in the form of a torus is not applicable to road surfaces without deformation. The increment of tensions in the tire material due to such deformation is described and it is pointed out that such rubbing action on the road surface, while simultaneous, is continuous and the sum of such effects must cause a portion of the resistance  $f$ . The author concludes that on account of both sources of resistance it is desirable to preserve the enamel of the road surface intact and free from all loose particles, and further that the interaction of road and tire must continue unfavorable both to road and tire, unless the section of the tire is made trapezoidal.

#### *Bituminous Surfaces on Brick Pavements:* ELLIS

R. DUTTON, assistant city engineer, Minneapolis, Minn.

The use of a bituminous coating on the surface of old and new brick paving is desirable and beneficial. It gives a more pleasing appearance to the street, reduces the noise, affords better foothold for horses—and lessens the wear of the brick.

A bitumen which would be satisfactory for this purpose should be of a very adhesive quality all the time, under all conditions of moisture and temperature, and should not become excessively

soft in hot weather—nor become brittle in cold weather.

It should be composed of such materials that would be and remain stable under all conditions and not evaporate or lose its most valuable properties.

It should be applied in the best and most approved manner, so as to produce the best results capable for the quality of the bitumen. The surface of the brick should be made perfectly clean, free from dust and moisture. The bitumen should be applied at the proper temperature—in a proper manner and under favorable weather conditions.

After application of the bitumen the surface should be covered with either fine granite or trap chips, torpedo sand or a coarse sand.

Such a bituminous coating would make the ideal brick pavement.

*Small Stone Block Pavements:* A. H. BLANCHARD, professor of highway engineering, Columbia University, New York City.

Illustrated with lantern slides of European and American pavements of this type.

*The Organization of Town Highway Departments:*

FRED BUCK, assistant deputy commissioner, New York State Highway Department, Albany, N. Y. There are three essential points to be observed in formulating any plan for the improvement of the highways of any commonwealth.

(a) A series of improved thoroughfares connecting the principal centers of population.

(b) A series of improvements to the highways which form the principal tributaries to those first mentioned.

(c) All highways in the commonwealth not included in the first two classes.

No plan for financing a scheme of highway improvement has yet been advanced which will make possible the improvement of a total of more than 12 per cent. of the mileage of any state, of the character indicated for classes (a) and (b) within the next 15 or 20 years; and any plan which contemplates the improvement of 12 per cent. of the mileage of any commonwealth without giving attention of some kind to the remaining 88 per cent., fails in large measure of attaining its full value to the commonwealth as a whole.

Roads comprising class (c), in this article, are, in the state of New York, under the jurisdiction of the Bureau of Town Highways, and since the organization of that bureau, very gratifying results have been accomplished.

With no greater town taxes than were raised

under the old "Labor System," about 3,600 miles of good town macadam roads have been built, about 8,400 miles of good gravel roads, and about 50,000 miles have been properly shaped and crowned and standardized as to width.

By furnishing plans and encouraging town superintendents to construct culverts and short-span bridges with their own local labor, utilizing local materials wherever possible, in 1911 there was effected a saving, in actual cash, to the taxpayers of the state more than three hundred and fifty thousand dollars, not taking into any account the vastly superior strength and durability of the structures so erected.

The results of the plan in New York seem to clearly prove that a thoroughly organized, well equipped town highway department is one of the essential parts of any general scheme of highway improvement.

*Brick Pavements for County Highways:* W. C. PERKINS, Niagara Falls, N. Y.

Presented by the author, and illustrated by lantern slides.

*A City Traffic Census:* W. H. MESSENGER, S.B., assistant engineer, Bureau of Highways, Brooklyn, N. Y.

The above bureau inaugurated a permanent census of its vehicular traffic in June, 1912. The forms used divide traffic into two large classes, rubber-tired and iron-tired, with appropriate subdivisions of each class. Starting with a small squad of six men, working eight hours a day, rain or shine, observations have been made at some 400 points mostly in duplicate. Duplicate observations are separated by a period of 15 days. A few night and Sunday records have been taken.

Results are tabulated to give the density and tonnage. The density is computed for number per foot of roadway per minute, per line of traffic per minute, and on the basis of traffic units as used by the London Traffic Branch. Tonnages are founded on extensive inquiry among those best knowing weights of different vehicles of business and recreation, and are assembled to give daily, weekly and annual amounts per foot of width of roadway, to the end that durability or total life may eventually be found for all classes of pavement.

The results thus far obtained have been used by the city planning committee, and are daily called for in connection with the determination of the class of pavements to be laid on certain streets in the immediate future.

This census was inaugurated by Mr. H. H. Schmidt, chief engineer, and placed under the charge of the writer.

*Petrographic Study of Rocks for Road-making in the Office of Public Roads:* E. C. E. LORD, petrographer, U. S. Office of Public Roads, Washington, D. C.

This paper contains a review of a quantitative, microscopic method of rock analysis by means of a cross-line field, and a brief statement of the principal road-making rocks, their method of classification and physical properties. Attention has been called to the effect of mineral composition and rock structure on the wearing properties of road materials.

It has been shown that the dense, fine-grained, igneous rocks (traps) are generally more tough and offer greater resistance to wear than the coarser grained igneous, or the more loosely textured sedimentary and metamorphic rocks. In consequence of their superior toughness, the screenings from trap rocks are found to be sharper and more wedge-shaped than those from other rock types and therefore produce a more permanent bond when compacted with the larger road stones.

This interlocking of the coarser portion of the screenings with the rock fragments forming the wearing course of the road constitutes the mechanical bond of the road surface, and should be distinguished from the cementing bond of the fine dust which is due to the presence of adhesive mineral substances of a more or less colloidal character. This cementing value has been found insufficient in many cases to withstand the effect of modern traffic and it has therefore been suggested to make use of the highly cementitious basic open hearth slag dust to overcome this difficulty.

*Field Methods for Laying Out Highway Curves:* HENRY B. DROWNE, instructor in highway engineering, Columbia University.  
Read by title.

*The Value of Microscopic Analysis of Rocks to be Used in the Construction of Roads and Pavements:* J. F. KEMP, professor of geology, Columbia University.  
Read by title.

*Municipal Plants for the Storage of Road Oil:* WILLIAM H. KERSHAW, chief engineer, Paving and Roads Division, The Texas Company, New York City.

After comment on the existing conditions regarding the lack of equipment for storing road oil, with its resulting economic loss, detailed statements of the cost of tankcar equipment is given, showing that all extra expense in the handling of road oil that results from lack of proper storage facilities eventually becomes a part of the cost of the oil. Figures given show that 12,000 gallon tanks can be erected at an approximate completed cost of \$700. A statement is made that the saving of the accumulating demurrage now charged by the railroads will pay for the erection of the tank and the saving in the cost of the oil will show an earning on the investment.

After describing existing municipal storage plants, a simple form of single compartment tank is suggested that will hold 12,000 gallons and is fitted with steam coils and on which all outside piping is steam jacketed, which will cost complete approximately \$700 and is capable of handling all of the heavier grades of binding oils and solid bitumens as well as the lighter grades of road oil.

*The Consistency of Bituminous Materials, its Determination and Value in Specifications:* MAJOR W. W. CROSBY, chief engineer to the Maryland Geological and Economic Survey, and consulting engineer, Baltimore, Md.

The consistency of a bituminous material is defined as its degree of firmness and determined by internal friction.

The determination of consistency is now usually made by one or more of half a dozen instruments designed on three general principles.

The instruments described, however, do not now cover in their range the entire field of materials and some materials are difficult of measurement in the matter of consistency by any of the older and more customary instruments.

The desirability of a single instrument for the purpose, whose range will cover readily the entire field of materials, is evident. Two such, newly proposed and as yet not generally used, are described. A modification in the customary methods of performing certain tests is advocated.

The value of a proper determination of consistency is shown by the dependence, on this characteristic, of the methods of using a material, by the information which such a determination gives concerning the probable results of such use, and concerning the value of the material itself.

Specifications containing definite descriptions of

the consistency of a pitch and drawn in physical terms are particularly appropriate for physical work such as road-building, and such specifications are more likely to be readily understood than where chemical expressions are used, perhaps to cover the same points in a less direct way.

The writer believes that valuable research work can be done by investigations into the consistency of bituminous materials or pitch compounds, and that from such work the art of road-building will be advanced.

*The Value of Specifications and Tests for Bituminous Materials:* CHARLES S. REEVE, chemist, U. S. Office of Public Roads, Washington, D. C.

The author urges the importance of purchasing bituminous materials upon a specification. The maker of such a specification, however, should know the relations to one another of the particular characteristics he demands, and the ability of the producer to meet his requirements. Advance samples and shipments should be tested to insure the acceptance of satisfactory material and to furnish records of tests which may prove of value later. Examples of recent neglect to fulfil certain specifications are given, and in some cases this neglect would have proved serious but for the fact that careful inspection averted the use of the undesirable materials. The practise of purchasing upon a trade name only is criticized, and an example is cited which shows a recent failure due to this practise. The author concludes by urging the highway engineer to protect himself by the careful purchase and inspection of materials.

*The Evaporation of Bituminous Materials, its Determination and Value in Specifications:* PREVOST HUBBARD, in charge Division of Roads and Pavements, The Institute of Industrial Research, Washington, D. C.

Read by title.

*Fixed Carbon in Bituminous Materials, its Determination and Value in Specifications:* LESTER KIRSCHBRAUN, director, Chicago Paving Laboratory, Chicago, Ill.

The writer describes the standard method of determining fixed carbon in bitumens, and points out some of the factors of manipulation necessary of observance in order to obtain correct and consistent results. A discussion of the derivation of fixed carbon produced upon ignition of bitumens is given, and its significance applied in three particulars. First, as a means of identification of certain native bitumens; secondly, as a means of

checking the suitability of combinations of flux solvents with hard, highly condensed bitumens; and again, as applied to oil asphalts, as an index of the severity of heat treatment to which such materials have been subjected in the course of their production. This latter feature is demonstrated by graphical data showing the effect upon the fixed carbon yield in runs of oil asphalt made from the same crude at different temperatures. The effect of the character of the crude from which these products are made as influencing the fixed carbon characteristics, and the application of this test to specifications, is pointed out.

*A Method for Determining the Toughness of Bituminous Materials:* J. E. MYERS, chief chemist New York State Highway Department, Albany, N. Y.

The toughness of bituminous materials is determined by filling a 3 oz. tin box (3.5 cm. deep by 5.5 cm. in diameter) with the melted material. The material is allowed to cool to room temperature. When cold the box is held by a pair of tongs, rapidly heated over a Bunsen burner, and the material emptied into a can of cold water. In heating, only enough heat is applied to free the material from the box, so when emptied into the water the material is still solid, being softened only on its exterior. By wetting the hands this cylindrical shaped piece of bitumen is easily rolled into a ball which will be free from seams.

The ball is maintained at the temperature at which the test is to be made (usually at zero degrees C.) for at least one hour before testing. The balls are tested in the impact machine adopted by the American Society for Testing Materials, for determining the toughness of rock used in macadam roads. The essential working parts of the impact machine are the anvil, of 50 kilograms weight; the hammer, of 2 kilograms weight, and the plunger, of 1 kilogram weight, the plunger having a hemispherical-shaped head of 1 cm. radius.

In testing asphaltic materials the drop of the hammer is taken from a height of 5 cm. for the first blow and the drop of each succeeding blow is increased 5 cm. The height from which the hammer falls when rupture occurs is given as the toughness of the material.

*Distillation of Tar. Methods of Determination, and Value in Specifications:* PHILIP P. SHARPLES, chief chemist, Barrett Manufacturing Co., Boston, Mass.

The methods in use and proposed for the distillation of tars and refined tars in road work are so varied and give such varied results that there is urgent call for their standardization. Attention is called to the excellent work of the Subcommittee on Distillation of Committee D—4 of the American Society for Testing Materials and their recommendations.<sup>1</sup>

The distillation test in a specification should be so drawn as to show, in conjunction with the free carbon, specific gravity and viscosity: (1) absence of water; (2) character of tars used; (3) method of refining. It is important that in addition to the amount of distillate, its specific gravity and the melting point of the residue be required.

*Classification of Rocks Used in the Construction of Roads and Pavements:* CHARLES P. BEEKEY, assistant professor of geology, Columbia University.

Read by title.

*Specifications for Patented Pavements:* WILLIAM H. CONNELL, chief, Bureau of Highways and Street Cleaning, Philadelphia.

Read by the secretary.

*The History of the Topeka Bituminous Concrete Pavement:* THEO. S. DELAY, city engineer, Creston, Iowa.

In the early days of the use of bituminous paving surfaces various arrangements of aggregate and various bituminous materials were used, the materials and methods being adapted to the work contemplated.

About the year 1893 Marcus A. Hodgman, a paving superintendent, in the employ of F. O. Blake, in Denver, reverted to some of the earlier practices in laying bituminous pavements.

Hodgman's work was seen by Frederick J. Warren, an employee of the Barber Asphalt Paving Company, who subsequently resigned from the employ of that company, went east, and took out a patent on a similar form of construction.

Warren organized the Warren Brothers Company to promote the invention and by vigorous promotion methods succeeded in having built a very considerable yardage of paving in accordance with this method.

Hodgman died in 1903, but Blake continued in the paving business and evidently still had a good opinion of Hodgman's idea, as he promoted some

pavement in accordance with that principle in Topeka, Kansas, about the year 1908.

Before this work was constructed, Warren Brothers Company brought suit for infringement of patent against the city of Topeka and the contractor. The defendants called on Blake for assistance to such good purpose that, when the case came up for trial, the plaintiff was willing to enter an agreed decree waiving claim of infringement but enjoining plaintiff against infringing.

Early in 1910 the city of Creston, Iowa, started proceedings for the construction of 25,000 yards of bituminous concrete paving and adopted the specifications used at Topeka. Creston also was made defendant in a suit by Warren Brothers Company, and this was settled by an agreed decree as in the Topeka case, but without any injunction clause.

Since it has become known that this form of pavement is free of difficulties it has been used very extensively in the middle west, with general satisfaction. It is not, however, a new form of construction, as it has been in continuous use in Pittsburgh, Pa., since 1897.

Its use has been instrumental in greatly reducing the cost of paving to the taxpayer, as may be seen by comparing prices at Creston with those of other places.

As this form of construction yields no exorbitant profits it has no promoters, hence has not met with acceptance as rapidly as its merits deserve.

It is subject to one objection common to all continuous pavements, namely, cracking under sudden changes of temperature. These cracks do no harm, show no inclination to ravel, and close up during warm weather when sufficient traffic passes to keep the pavement worked.

*Economical Methods of Repairing Sheet Asphalt Pavements:* H. B. PULLAR, assistant manager and chief chemist, The American Asphaltum and Rubber Co., Chicago.

*Observations on Slipperiness of Bituminous Surfaces and Bituminous Pavements:* W. D. UHLER,

<sup>1</sup> *Proceedings of the American Society for Testing Materials*, Vol. XI., 1911.

assistant chief, Bureau of Highways and Street Cleaning, Philadelphia.

Read by title.

*The Mixing Plants Used in the Construction of the Topeka Bituminous Concrete Pavements of the Borough of Queens in 1912:* A. F. GRUENTHAL, assistant engineer, Bureau of Highways, Borough of Queens, N. Y.

Read by title.

*Bituminous Gravel Concrete Pavements:* SPENCER J. STEWART, division engineer, New York State Department of Highways, White Plains, N. Y.

This pavement consists of mixing Hudson River cementitious gravel, heated to a temperature of over 225 degrees F., with natural lake asphalt heated to a temperature of not less than 275 degrees F., then placing both ingredients in a mechanical revolving mixer and thoroughly agitating until all the particles of the mineral aggregate are thoroughly and completely coated with the bituminous material.

This mixture, at not less than 250 degrees F., is then spread upon the prepared bottom or foundation course.

The gravel is composed of calcareous sandstone, granite and quartzite, associated with a considerable amount of finer particles of the above-named rocks, together with a percentage of clay. This latter substance gives the gravel a good cementitious value, which is an essential to the comparative permanency of the pavement. The clay acts as a catalyzer on the asphalt, making it more viscous, less volatile and also less brittle.

The advantages of this pavement are:

First, its comparatively low cost over so-called semi-permanent pavements.

Second, on account of its adaptability to country and parkway purposes, due to its easy riding surface and its conformity to our ideals of the surroundings of a parkway or country highway.

Third, on account of its non-slippery nature, it being practically a "non-skid" road.

From the contractor's bids, the average cost of this pavement is about \$0.85 per square yard.

## SOCIETIES AND ACADEMIES

### THE HELMINTHOLOGICAL SOCIETY OF WASHINGTON

THE fifteenth regular meeting of the society was held at the residence of Dr. Ransom, March 20, 1913, Dr. Ransom acting as host and Mr. Chambers as chairman.

The comparative anatomy of the free-living and the parasitic nematodes was discussed by the society.

Mr. Crawley presented a note reviewing Muriel Robertson's work on *Trypanosoma gambiense* and its vector, *Glossina palpalis*. She has shown there is a rhythmic cycle in the life of the trypanosome in the vertebrate host, the parasite falling off in numbers at times until there are only a few small forms present, which then begin to multiply with a resultant production of larger forms until the blood contains numerous large forms, and the cycle repeats. An endeavor to correlate this alternation of few small forms and numerous large forms with the infectivity of the trypanosomes for its invertebrate host, the tsetse fly, developed the fact that the infectivity was at its maximum when the few small trypanosomes were in the blood and at its minimum when the many large forms were present.

Dr. Ransom presented a note on "The Reported Hosts of *Cysticercus cellulosæ*." It is commonly stated in general works on parasitology that *Cysticercus cellulosæ* occurs not only in the pig, its usual host, and in man, a not uncommon host as a result of auto-infection, but also in the dog, cat, bear, sheep, deer, rat and monkeys. It has also been reported from a seal.

The only hosts, however, in which the occurrence of *Cysticercus cellulosæ* can be considered to have been proved are the first three named. The reputed occurrence of *C. cellulosæ* in the cat, bear, rat and seal rests apparently upon a single instance of the discovery of cysticerci resembling *C. cellulosæ* in these hosts without proof by feeding experiments. Likewise, though several cases of *C. cellulosæ* have been reported from monkeys and rather many cases from sheep and deer, no experimental proof or other evidence of a conclusive nature that the parasites in question were really *C. cellulosæ* has been furnished. On the contrary, the evidence thus far available tends to prove the non-occurrence of *C. cellulosæ* in these animals, particularly in the case of sheep and deer. It has, in fact, been recently shown (Ransom, 1913) that the muscle cysticercus of sheep

resembling *C. cellulosa* is the intermediate stage of a dog tapeworm; consequently very definite and detailed evidence must be produced before any case of cysticercus in sheep can be accepted as a case of *C. cellulosa*. Similarly, more definite evidence than has been furnished in the various reported cases of muscle cysticerci in deer will be required before any such can be accepted as a case of *C. cellulosa*. Though it is perhaps not surprising that the muscle cysticerci of sheep should have been accepted as *C. cellulosa* in view of the fact that sheep commonly live in rather close relationship with human beings, it does seem, on the other hand, surprising that the reports of cases of *C. cellulosa* in deer should not have been questioned heretofore. Furthermore, it would seem, in view of the fact that it has long since been shown (Moniez, 1879) that the cysticerci in reindeer somewhat resembling *C. cellulosa* are the larvæ of a dog tapeworm, that observers of cysticerci in other deer would have hesitated to identify them as *C. cellulosa*, yet no one appears to have doubted the correctness of such an identification. Even in certain cases in which it was noticed that the hooks did not correspond perfectly to those of *C. cellulosa* the observer nevertheless concluded that the parasites were actually *C. cellulosa*. The history of *C. cellulosa* emphasizes the necessity of guarding against the indiscriminate acceptance of host records. As a general rule records of the same species of larval tapeworm from a variety of hosts should be considered of doubtful correctness unless supported by feeding experiments or other conclusive evidence.

MAURICE C. HALL,  
Secretary

#### THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

A SPECIAL meeting of the society was held at 4:30 P.M. on March 25, 1913, in room 43 of the new building of the National Museum, the president, Mr. Stetson, in the chair.

Dr. George Grant MacCurdy read a comprehensive paper on "Ancient Man, His Environment and Art."

This paper dealt with the environmental factor in human development; the newly discovered human remains from Piltown, Sussex, and their significance; recent finds in the terraces of the Somme Valley; San Isidro, near Madrid; Torralba, a large camp site in the province of Soria, Spain, where a rude stone industry associated with an ancient fauna has been found; caves on the

Island of Jersey occupied by Mousterian man; typical caves and rock shelters of southern France: La Quina, La Ferrassie, Placard; the art of the cave man in France and Spain: Altamira, Castillo, La Pasiega, Covalanas, Pindal, Font-de-Gaume, Cap Blanc, Niaux, Gargas, Laussel, Alpera, Cogul; representations of the human form; La Combe, a cave in the Dordogne excavated last summer by Professor MacCurdy; Tuc d'Audoubert, a Pyrenean paleolithic cavern of great beauty discovered last July; its parietal art and the unique figures of the bison modeled in clay; paleolithic art in its relation to magic; some of the causes which led to its development and eventually to its decay.

The lecture is based largely on first-hand observations by the lecturer during the past summer. The lantern slides reproduce faithfully in color the remarkable paleolithic cavern frescoes. The epochs covered by the lecture beginning with the oldest are: Eolithic or pre-Chellean, Chellean, Acheulian, Mousterian, Aurignacian, Solutrean, Magdalenian and Azilian. These are all pre-Neolithic.

Several questions were asked and answered.

W. H. BABCOCK

#### THE CLEMSON COLLEGE SCIENCE CLUB

THE regular monthly meeting of the club was held on Wednesday evening, January 15. The first paper was by Dr. R. N. Brackett, head of the department of chemistry, entitled "The History of the Clemson College Science Club." There was a great deal in this that was very interesting, as Dr. Brackett presented same in a very entertaining manner and pointed out that the club had entertained and had before it some distinguished men in its history.

The next paper of the evening was by Professor J. N. Harper, director of the agricultural department and of the South Carolina Experiment Station, on the "Mendelian Law." This was treated from the standpoint of his own experiments and observations on this law. He very lucidly gave the history of Mendel and the explanation offered by him for the operation of his law. It is of decided interest also that Professor Harper has done original work along this line and has evolved an explanation for the working of the law that has invariably been borne out in his observations and experiments.

F. R. SWEENEY,

## THE GRAMERCY-PRECISION BALANCES

*Made Entire of Magnalium      For Students' Use and Technical Purposes*

The unsightly appearance of ordinary students' balances, with wooden base and lacquered metal pillar, beam, pans, etc., after they have been in the laboratory for a short time, subjected to acid and other laboratory fumes, has made the Gramercy Precision Balances meet with immediate favor in educational and industrial laboratories throughout the world.

The balances are made entirely of magnalium, and lacquered with a durable colorless substance. They are light in weight, most durable, and elegant in appearance.

The prices are very moderate.

*Descriptive pamphlet on request*

## THE ADVANCEMENT OF SCIENCE

A book of special interest to scientific workers and to those who desire to keep in touch with science because it has enlisted the cooperation of scientific men in setting forth authoritatively and accurately the substantial gains in all departments of investigation, scientific work and thought, during 1911–1912, in all countries. It provides in careful, critical reviews a general narrative survey, with the latest results, of progress in *Astronomy, Geography, Geology, Meteorology, Physics, Chemistry, Biology and Zoology, Botany, Anthropology, Archaeology, Philology and Philosophy*, covering fully subjects ignored or but meagerly dealt with in the ordinary type of year-book, and covering them with authority.

The contributors on scientific topics, with the headings under which they describe recent progress, include:

- Prof. H. H. Turner**, Pres., Royal Astronomical Society: *Astronomy* (Recent Work on Solar Phenomena, Fluctuations of the Moon, the Minor Planets, Comets and Variable Stars, etc.)
- Prof. Cleveland Abbe**, of the United States Weather Bureau: *Meteorology* (International Ballooning, Aerolites, Secular Change of Climate, Sunspot Influences, etc.)
- E. E. F. d'Albe**, author of "The Electron Theory": *Physical Science* (Advances of Spectroscopy, Chemical Analysis by Alpha-Rays, Fused-Silica Standard, etc.)
- P. C. Mitchell, F.R.S.**, Sec., Zoological Society, London: *Biology and Zoology* (Disease-Bearing Arthropods, the new Fossil Primate, Recent Work on Heredity, Variation and Mendelism, etc.)
- W. L. H. Duckworth**, of Cambridge: *Physical Anthropology* (Homo-Primigenius, Andamanese and Malay Aborigines, new Observations on the Brain, etc.)
- R. R. Marett**, of Oxford: *Cultural Anthropology* (Eoliths, Palæolithic Age, Azilians and Neolithic Age, Ethnological Method, etc.)
- C. O. Blagden**, joint author with Prof. W. W. Skeat of "Pagan Races of the Malay Peninsula," etc.: *Philology* (The Austric Family of Languages).
- Prof. W. M. Flinders Petrie** of London: *Egypt* (Results of recent Studies in Nubia, etc.)
- Dr. D. G. Hogarth**, of the Ashmolean Museum: *Hittites* (New Light from Excavations at Jerablus and Sakjegeuzi, etc.)
- Prof. R. M. Burrows**, Chairman of the Aegean Islands Committee: *Crete* (Progress in Excavations at Cnossus, Tyllissus, Hagia Triada, near Gournia, etc.)
- Prof. Percy Gardner** of Oxford: *New Light on Greek Art*.
- Prof. A. E. Taylor**, of St. Andrews: *Philosophy* (Henri Bergson, The New Realism, Revival of Theism, Varisco, Thomism, etc.)

## THE QUICK SUCCESS

of the Britannica Year-Book, announced in March, is easily explained. It met with singular completeness a need of the hour. The vast complexity of modern interests during the last year—social, scientific, political, artistic, literary, industrial, commercial and practical—has been subjected to an illuminative and critical survey and estimate by international authorities. It is *World-wide* in its Sweep, an indispensable explanatory companion to the newspaper, the magazine and the technical journal.

## A BARGAIN

for Those Who Act At Once. The Britannica Year-Book is remarkably cheap. Printed on India paper, a volume 1 inch thick, it contains 1260 pages, about 900,000 words—equal to eight or nine average volumes. The purchaser receives more than 500,000 words for a dollar. The before-publication prices are *one half* what other publishers would charge. Readers of this notice should send remittance immediately, in order to profit by the concession in price allowed *only until April 21*. Sent post-paid anywhere in the United States or Canada, upon receipt of price.

[These prices to be increased by 50 cents after April 21]

## University Control

By J. McKEEN CATTELL, Professor of Psychology in Columbia University

Together with a series of Two Hundred and Ninety-nine Unsigned Letters by Leading Men of Science holding Academic Positions and Articles by JOSEPH JASTROW, GEORGE T. LADD, JOHN J. STEVENSON, J. E. CREIGHTON, J. McKEEN CATTELL, GEORGE M. STRATTON, STEWART PATON, JOHN JAY CHAPMAN, JAMES P. MUNROE and JACOB GOULD SCHURMAN.

A great variety of questions concerning general university administration are dealt with in an original and helpful way.—*Nature*.

These quotations and examples are taken from Professor Cattell's informed and thorough discussion of the subject of university control, a subject upon which he has had much to say of late, finding occasion for caustic criticism of existing American conditions, and standing as the champion of an academic democracy and a teaching profession upon which a man may enter without forfeiting his self-respect.—*The Dial*.

Sentences and paragraphs that betoken the expert, highly-trained mind, the suggestions that come to refresh and tell us that a new day is about to dawn in educational writing.—*The Boston Evening Transcript*.

## Science and Education

A series of volumes for the promotion of scientific research and educational progress

VOLUME I. THE FOUNDATIONS OF SCIENCE. By H. POINCARÉ. Containing the authorized English translation by GEORGE BRUCE HALSTED of "Science and Hypothesis," "The Value of Science," and "Science and Methods."—*In Press*.

VOLUME II. MEDICAL RESEARCH AND EDUCATION. By RICHARD M. PEARCE, WILLIAM H. WELCH, W. H. HOWELL, FRANKLIN P. MALL, LEWELLYS F. BARKER, CHARLES S. MINOT, W. B. CANNON, W. T. COUNCILMAN, THEOBALD SMITH, S. J. MELTZER, JAMES EWING, W. W. KEEN, HENRY H. DONALDSON, CHRISTIAN A. HERTER, and HENRY P. BOWDITCH. *In Press*.

VOLUME III. UNIVERSITY CONTROL. *Now Ready*.

## Mayne and Hatch's High School Agriculture

By D. D. MAYNE, Principal of School of Agriculture and Professor of Agricultural Pedagogics, University of Minnesota, and K. L. HATCH, Professor of Agricultural Education, University of Wisconsin.

\$1.00

This course has a double value for pupils in the first years of the high school. On the one hand, it puts the study of agriculture on a serious basis, and teaches the young beginner how he can carry on the work of a farm most profitably. On the other hand, it affords an interesting introduction to all the natural sciences, enabling the student to master certain definite principles of chemistry, botany, and zoology, and to understand their application. A few experiments are included, which may be performed by the student or by the teacher before the class. But the subject is not made ultrascientific, forcing the student through the long process of laboratory method to rediscover what scientists have fully established. The topics are taken up in the text in their logical order. The treatment begins with an elementary agricultural chemistry, in which are discussed the elements that are of chief importance in plant and animal life. Following in turn are sections on soils and fertilizers; agricultural botany; economic plants, including field and forage crops, fruits and vegetables; plant diseases; insect enemies; animal husbandry; and farm management.

## The Mathematical Theory of Heat Conduction

With Engineering and Geological Applications.

By L. R. INGERSOLL, Associate Professor of Physics, and O. J. ZOBEL, Formerly Fellow in Physics, University of Wisconsin

8vo, cloth, 171 pages, with diagrams. \$1.60

This book may be used as a first book in Mathematical Physics, and it will also be serviceable to geologists and engineers. The applications take up and solve practical problems, many of which are here treated for the first time.

Questions of the cooling of the earth with and without radioactive influences, and several cases of cooling magmas, are among the problems included for the geologist; while in technical lines, problems in the tempering of steels, freezing of concrete, electric welding and other examples are considered.

The applications are numerical in nature, based on the best obtainable data, and illustrated with numerous diagrams. Their reading is facilitated by numerous mathematical and physical tables in an appendix, which serves in great measure to make the book complete in itself.

## INSTRUMENTS OF PRECISION

For the Study of the Circulation

**JAQUET SPHYGMOCARDIOGRAPH** for the simultaneous recording of three different tracings in addition to the chronograph record. One tambour must always record the pulsation of the radial artery with which it is in contact when the instrument is in position. The other two tracings may be from the carotid, jugular, apex beat, etc., as desired.

**USKOFF SPHYGMOTONOGRAPH.** The unique feature of this instrument is the simultaneous recording of the blood pressure in millimeters of mercury together with the brachial pulse at varying pressures, and one other tracing such as the carotid or jugular pulse or apex beat, and also time in 1/4 seconds. In other words, there are four tracings upon the paper, three of which are fixed by the limits of the apparatus, i. e., blood pressure in millimeters of mercury, arterial pulsations at various pressures and time tracing, while the fourth record may be taken at pleasure from either the jugular vein, carotid artery or apex beat.

**MACKENZIE INK POLYGRAPH.** Original English make. This instrument records two simultaneous tracings only, i. e., radial pulse and other, such as carotid, jugular, apex beat, etc., the great advantage being the avoidance of smoked paper and the convenience and permanency of the ink tracings, which may be continued almost to any length from the long roll of paper supplied with the instrument.

**ELECTRO-CARDIOGRAPH APPARATUS.** In this outfit the electro-motive force from the contracting heart muscle is measured by the use of the Einthoven String Galvanometer, an instrument of exceeding sensibility. A fine platinum or quartz thread constitutes the suspension of the galvanometer, the thread being deflected to one side or the other as the electro-motive force from the heart varies in strength. By the use of an arc lamp and a microscope system, the thread being of microscopic fineness, a photograph of this thread is thrown upon a sensitized paper which is set in motion during the exposure.

## THE FUNCTION OF RESEARCH IN THE REGULATION OF NATURAL MONOPOLIES<sup>1</sup>

THE social and political unrest of the present day, which manifested itself strikingly in the recent presidential campaign, is of course due to more than one cause. Senator Root, in a notable speech recently delivered before the New York Chamber of Commerce, attributed this unrest in large measure to the mutual distrust and mutual misunderstanding existing between the leaders of the financial and industrial world, on the one hand, and the great body of the American people, on the other. To a large audience of bankers, merchants and captains of industry he said:

There are hundreds of thousands of people outside our great industrial communities who think you are a den of thieves. There are hundreds of thousands of people who think the bankers and manufacturers are no better than a set of confidence men.

We have before us now great and serious questions regarding the financial problems of the country, and this is what stands in the way of their solution: It is that the men who understand the finances of the country and the merchants engaged in great operations are under suspicion; great bodies of people will not accept what they say about finance. They will not accept what the experts say because they do not believe their motives are honest. . . . On the other hand, what is your attitude toward the people? There are many in this room to-night who down deep in their hearts believe that great bodies of the American people really want to destroy their business and confiscate their property. Now, neither of these things is true; but one misunderstanding leads to conduct which seems to justify another.

<sup>1</sup> Retiring presidential address before the Philosophical Society of Washington.

Senator Root then went on to say that there is nothing more important to-day than that by education and the spread of ideas such misunderstanding shall be done away with; that Americans shall interpret the spirit of popular government so that each shall be ready to do justice to the other, and every American shall desire the prosperity and happiness of every other American.

But while there is great force in what Senator Root says, it remains true that this social unrest springs in a measure from causes which the government can remedy.<sup>2</sup> The part which the government must play in our complex civilization is constantly increasing, and is immensely more important than in the simpler civilization of a century ago. In the early days the individual was much more independent, and each community was much less dependent on other communities than now. Society was simple, communication and commerce were limited, and relatively few laws sufficed. The twentieth century differs from the eighteenth in many respects, but in none more strikingly than with regard to the increasing complexity of business dealings.

The regulation and control of large corporations which have virtually secured the monopoly of particular industries is now receiving the attention of many of our leading scholars and statesmen, and the solution of the problem will be a triumph for popular government. The means that may be employed for this purpose are not so restricted as they formerly were. The public is becoming educated rapidly, and the constitution has greater capacities now than formerly.

#### STATE REGULATION OF NATURAL MONOPOLIES

While the federal government in the

<sup>2</sup> In other words, the people acting cooperatively through their chosen representatives can remedy.

last few years has been striving to break up giant aggregations of corporations into their constituent parts, with the hope of getting these parts to compete with one another and so put an end to an undesirable monopoly, some of the states have been dealing in constructive fashion with another class of monopolies, and showing how they can be regulated and controlled to the end of conserving the best interests both of the public and of the stockholders. I refer to that very large and important class of corporations known as public-utility companies, chief among which are the steam railways of the country, city and interurban electric railways, gas and water companies, electric light and power companies and the telephone and telegraph companies. The federal government through the Interstate Commerce Commission has of course taken a leading part in this development, particularly with respect to the railways of the country, but the work done by some of the state public-service commissions, prominent among which are the commissions of Massachusetts, Wisconsin and New York, is of far-reaching influence and importance.

The attitude of the public regarding public utilities has been undergoing a profound change in recent years. Formerly a franchise for a street-railway or gas company, for example, was usually granted without compensation to the city, with few, if any, obligations on the company, with no control by the city over prices or service, and with extensions of the service into new territory optional with the company. Competition was sometimes sought by granting a franchise to more than one company, but generally such competition, if any, made the service poorer to the public as well as the profits less to the stockholders. If the business was profitable and the franchises valuable, city coun-

cils would be corrupted, if necessary, to get what was wanted. And, if the dividends were large, as they often were when no standards were set as to the quality of service and no limit set as to price, the capital would be sufficiently watered to keep down the dividends (capitalizing the value of the franchise, it was called). Occasionally a city became so dissatisfied with its gas or water or electric light company (either as to prices or service, or both) that in despair it built a new works, and two plants were operated where one, if rightly managed, would have served the public better.

#### ADVANTAGES OF A MONOPOLY

The change from this condition to the present (at least in certain states) is nothing short of revolutionary. It is now coming to be recognized that competition can not regulate rates in public utilities, and that one company can generally give better and cheaper service than two. It is a waste of capital and a disadvantage to a city to have two sets of gas or water pipes in the ground, or two sets of telephone or electric light wires and poles encumbering the streets. Having two telephone companies in a city forces a large proportion of their patrons to pay for both services; two street railway systems generally give less satisfactory service and fewer transfers than one would do. In short, these utilities are natural monopolies, and the highest efficiency and lowest rates are only possible when each one has the entire business of a given city or territory. So long as the right to regulate public service companies was denied, the idea of granting monopoly privileges was repugnant, and hence competition was encouraged with the hope of escaping the ill effects of unregulated monopoly. But now that the right and duty of regulating all public-service

corporations is admitted by the companies themselves as well as by the courts, the ill effects of monopoly may be escaped and at the same time the beneficial results of economy and efficiency may be realized. To understand what effective regulation involves, we must consider the obligations imposed upon public utility companies, and the character of the service rendered by each.

When a community grants an exclusive franchise for a term of years or for an indefinite period to a corporation, with the right to regulate the quality of the service it shall render and the prices it may charge for such service, it undertakes a serious responsibility. The interests of the public must be safeguarded, but at the same time the interests of the company and its stockholders must be respected. A public-service commission, equipped with a full knowledge of the technical, commercial and legal aspects of the business, and endowed with a judicial spirit, will see that the following duties are fulfilled by each public-utility company in its jurisdiction:

1. To perform any duties especially prescribed by law.
2. To serve all who request service and make no discriminations.
3. To provide safe and adequate service.
4. To charge just and reasonable rates.
5. To fulfill its duties to its stockholders honestly and efficiently.<sup>3</sup>

#### REGULATION OF A GAS COMPANY

For example, a gas company receives a franchise to manufacture and sell gas for light, heat and power in a given city, for a

<sup>3</sup>This of course supposes that the commission has been given the necessary authority by the state legislature. Many of the public-service commissions were created as railroad commissions; and of these, some have had their functions extended to cover only a part of the duties mentioned above.

term of years, the city perhaps to have the right of purchasing the plant at the end of the franchise period. The quality of gas and the character of the service furnished, and the prices charged, are to be fixed by the public-service commission.

The commission must see that the company runs its mains into all the streets of the city, so as to give service to all; that uniform rates are charged and no rebates are allowed to favored customers; that service charges, if made, are reasonable; that the gas is of good quality, and as free from impurities as possible; that its heating value and candlepower are kept up to the standard specified; that the methods of testing and the instruments employed are up to date and satisfactory, and the persons doing the testing are competent; that the pressure of the gas is sufficient and not too great and does not vary enough to be dangerous; that gas appliances used are as safe as can be obtained, and connected in an approved manner; that the mains are properly located and properly protected from extremes of heat and cold; that the meters are kept in good order and tested from time to time as to their accuracy; that the prices charged are as low as possible, consistent with a reasonable dividend to the stockholders; that the books are kept in an approved form, so that the state of the business can readily be determined by the commission; that proper allowances are made for plant depreciation, or proper sums expended for upkeep; that no new stock is sold without approval by the commission, and that all dividends shall be from actual earnings, but that if actual net earnings are more than necessary to pay a reasonable dividend, the price of gas shall be reduced. This usually involves an appraisal of the company's property to determine whether the capitalization is fair. From time to time the specifications for

the quality of the gas and the methods of testing must be revised; the question may arise as to what candlepower or heating value will give the best service under prevailing conditions; new methods of manufacture, new appliances and new uses for the gas will all bring up new questions; and the commission must be prepared to consider and decide upon all kinds of scientific, engineering and commercial problems as they arise in connection with the regulation of gas companies.

These duties are so many and so varied that one might suppose that it would be impossible for a commission to accomplish them all even for a single company, much less for all the gas companies in a state. If it had never been done, it would indeed appear doubtful. But these functions are being performed (at least in large part) so successfully in a few states that many of the other states are looking forward to doing it as soon as their commissions are prepared for the work. The gain from such regulation is not alone to the public, which pays for and uses the gas. The company is saved from unfair and hostile local legislation, which often forces resort to the courts, always an expensive and often unsatisfactory experience. The business is more stable, customers are better served and better satisfied, the credit of the company is often improved, new stock sells more readily and at higher prices, as the public knows the condition of the business and there is less risk to the investor. Stock manipulation is prevented, and those who profit by that process are the only ones to suffer.

#### REGULATION OF AN ELECTRIC LIGHT COMPANY

Similar duties devolve upon a public-service commission with regard to other utilities. Electric-light companies are

regulated with respect to their schedule of rates; discriminations which are so frequent under ordinary circumstances must be prevented; wires, whether overhead or underground, must be run in such manner as to reduce the danger to the public; high-potential wires must be especially guarded to keep them from telephone and other low-potential wires; alternating current transformers must be grounded on the secondary side, and the grounds must be made according to approved specifications; the steadiness of electric potential and uniformity throughout a given city must be satisfactory; proper precautions must be taken to safeguard the lives of the linemen and other employees of the company; the meters must be frequently tested and provision made for extra tests on complaint; portable and station instruments must be tested; lamp renewals must be regulated and prices approved for other than free renewals and rules and regulations made (in the absence of local rules) with respect to street lights.

#### REGULATION OF OTHER UTILITIES

Street railways and interurban electric railways must be regulated with respect to kind and quality of cars; the speed of cars and car schedules; kind of brakes, headlights, doors and other safety appliances; the method of car heating and amount of heating required; the method of car lighting and the quality and amount of light that must be supplied; how the current is distributed from the sub-stations to the cars, and the variations in voltage permitted between sub-station and cars; how the railway current is returned from the cars to the sub-stations, in order that the resulting electrolysis may do the minimum of injury to gas and water pipes, lead-sheathed cables and other underground structures; the repairs and upkeep of

roadway and rolling stock; the fares to be charged and the conditions under which free transfers are issued; the wages paid employees and hours of labor; the conditions under which new stock may be issued; approval of plans for extensions or alterations of the system, etc.

Telephone companies must be regulated with respect to method of running their wires, so as to give the best and most reliable service possible under given circumstances; when and where wires must be put underground; the precautions to guard overhead wires against coming into contact with high-potential electric light or power wires; when and under what circumstances telephone and high-potential electric wires may be put on the same poles; the rates to be charged for different classes of service, both local and long distance; the service arrangements between different companies, the restrictions imposed by telephone companies respecting private exchanges and extensions; discriminations by a powerful company against smaller independent companies, etc.

Both the Interstate Commerce Commission and the state commissions deal with problems arising in connection with the regulation of the railroads, and these problems are numerous and of great importance. The first class of problems is connected with the fixing of freight and passenger tariffs, and discriminations in rates as between one locality and another or between one shipper and another. The second class of problems has to do with the operation of the road, with the safety and the adequacy of the service. This includes the question of the character of the road-bed and rails, the kind and quality of the engines and cars, the brakes and signaling apparatus, the kind of headlights and the candlepower and distribution of the light from the same; the heating, lighting and

ventilation of cars; the investigation of accidents; the weighing of freight and the testing of the scales, including the scales on which empty and loaded cars are weighed. These and many other questions may come before both state and federal commissions, but not all of them have been fully considered as yet by either. Similar duties pertain also to other utilities that are essentially monopolies, as telegraph companies, express companies, sleeping-car companies, water-supply companies, local express, transfer and cab companies. In so far as these utilities carry on an interstate business, they are also dealt with by the federal interstate commerce commission.

#### COOPERATION NECESSARY IN REGULATION

It appears from the above formidable, although incomplete, list of duties devolving upon a state public-utility commission that to fully measure up to its responsibilities would require a considerable staff of engineers, accountants and scientific assistants, besides its traveling inspectors and administrative officers. To decide many of the questions arising requires more technical knowledge than the experts either of the commission or the utility companies possess. Indeed, many of the questions can only be answered by extended researches carried out by scientists, engineers or statisticians working with the best of facilities. The interests at stake are in the aggregate so great that such researches ought to be made, and yet the cost would be too great for every state to do the work independently, or even for the richest of the states to undertake it alone.<sup>4</sup> The best

<sup>4</sup> Extract from Professor R. T. Ely in his "Outlines of Economics," 1908:

"The tasks which confront such commissions are stupendous, and the expense of conducting their work, when it is properly conducted, is enormous. . . . On the whole, however, it is fortunate

way in which the work can be well done and kept up to date is for all the states to cooperate, and for the federal government to assist and coordinate the work. This is being done to some extent already, although comparatively few of the states as yet have commissions that are handling public utilities generally, and hence the work is only fairly begun. On the part of the federal government, the Interstate Commerce Commission and the Bureau of Standards are cooperating with the state commissions, the latter with regard to standards and engineering questions which fall within its province. Some of these questions may be mentioned briefly.

#### INSTRUMENTS AND STANDARDS

The instruments and standards employed in the measurement of heat, light and electrical power have been the subject of much study and investigation at the Bureau of Standards. The thermometers and pyrometers of various kinds employed in temperature measurements, and calorimeters of different types for use in measuring the heat of combustion of gases and solids, are calibrated and certified by the bureau, and standard samples of certified calorific value are furnished, so that the testing apparatus of public-service commissions, public-utility companies and consulting engineers will agree (or special tests be made if they disagree) and causes

that the public have resolved to give this method of reform a thorough trial. It seems to be the next logical step in the evolution of natural monopoly, and does not appear to be attended with any grave danger. If it fails it will at least have trained up a corps of public servants thoroughly familiar with the operation of public-utility enterprises, and will at the same time have thoroughly convinced the people that there is no other alternative but public ownership and operation." This was written five years ago, and much progress has been made since then.

for dispute are thereby removed. The methods of testing with such apparatus have been studied by the bureau and sources of error in apparatus and methods determined. As manufacturing methods are developed and refinements in works control are introduced, greater accuracy in testing is required, and it is a great advantage to the industries to have uniform and reliable instruments, standards and methods.

The same may be said respecting the measurement of light and illumination. The candlepower of a gas flame depends upon the quality of the gas, the kind of burner used, the height of the barometer, the amount of moisture in the atmosphere and the degree of purity of the air in which it burns; hence, if the quality of the gas is to be determined (in part) by the candlepower given, it is necessary that the test be made under very definite conditions. The bureau has done considerable work on flame standards employed in gas testing, but much remains to be done in this respect. Photometric standards are supplied by the bureau for use in testing electric lamps of various kinds and colors, and gas standards are calibrated and certified. Thus, uniformity of value in light measurement is secured for the whole country, and indeed by means of international comparisons made by the bureau for the whole world, the international candle being the name of the unit of light universally employed in this country. Calibrations are also made of photometers and auxiliary apparatus. Similar uniformity, together with a much higher degree of precision, have been attained in electrical measurements. Electrical energy is sold by the kilowatt hour or the kilowatt year (or a combination of the two) and a large amount of testing is done by the companies and commissions to insure accurate meas-

urement of the energy delivered. Here again uniformity and accuracy are promoted by having a national laboratory for calibrating and certifying standards and instruments, and settling such disputes as may arise from disagreeing measurements. A large amount of work has been done by the bureau to secure and maintain accurate standards and instruments, but much remains to be done, particularly with reference to the specifications of instruments and apparatus and the improvement of methods of measurement and testing.

In addition to its work on instruments and standards, the bureau has carried out other investigations which have a bearing on the work of the public-service commissions. One of these is concerned with the specifications of illuminating gas, and the methods of testing to be employed in controlling its quality.

#### REGULATION OF GAS COMPANIES

Among public-service utilities, none has been for so long a time and in so great detail subject to legal requirements and restrictions as the gas business. Such regulation is of course intended to insure good service. Many elements go to determine good or poor service, the principal of which (chemical purity, heating value, candlepower and condition as to pressure of the gas) are enumerated and defined more or less completely in many of the gas ordinances now in force, together with the tests that shall be made and the penalties for failure to meet the requirements. These ordinances are sometimes, therefore, very technical and contain detailed specifications. In other cases the specifications are very meager. In some cases old ordinances long since out of date, so far as their technical specifications are concerned, are still in use; in other cases, old ordinances have been extensively amended; in

still other cases entirely new ordinances have superseded old ones; in many cases no regulatory ordinances have ever been adopted. In some states possessing state commissions, the requirements have been fixed by the commissions. But in most states (and in all until recently) regulatory ordinances have been prepared and passed by state legislatures or city councils. The process of adopting such an ordinance is often long and painful. Suspicion, antagonism and often political considerations combine to make the negotiations difficult, and sometimes it amounts to a long-drawn battle. The representatives of the city endeavor to get all they can for the public, the company yields as little as possible. The result is generally unsatisfactory to both. Because the standard of performance demanded of gas companies in different cities and states was so different, and because so much difference of opinion existed among experts as to what could fairly be required of a gas company under given conditions, the Bureau of Standards took up about three years ago a careful study of the subject of state and municipal regulations of the quality, purity and pressure of illuminating gas supplied by gas companies.

#### INVESTIGATION CONCERNING REGULATION OF GAS COMPANIES

A compilation of all the state laws and city ordinances in force in the country was first made, and their technical requirements tabulated. A detailed study was then undertaken of the various features of such laws, and an attempt made to formulate a model law that should contain reasonable standards of quality, purity and pressure, and a reasonable set of operating requirements. In this study, a large number of the best informed gas experts in the country were consulted, and

many gas plants visited. In this work the bureau has been assisted by the responsible officers and members of the technical staffs of gas companies and by members of public-service commissions, gas inspectors and consulting engineers. The bureau has endeavored to consider all sides of the various questions involved, and has of course received very conflicting opinions on some questions. It has been a source of great gratification to those conducting this investigation to see the fairness and broad-minded spirit shown generally by representatives of the gas companies in discussing questions that affected them so vitally. They have met a spirit of fair play by a corresponding willingness to reach just conclusions.

The results of this investigation were published by the Bureau of Standards, and the paper has had a wide circulation and careful study by those most interested in the subjects treated. Since its publication, the bureau has continued to study the subject, and is now preparing a revision of the first edition. The compilation of laws and ordinances will be revised and some important changes will be made in the model ordinance proposed. These changes are, however, being discussed very fully before publication, both with representatives of the public-service commissions and of the gas companies, the latter including a special committee of the American Gas Institute.

The position of the bureau in this matter, as in so many others, is advisory. It has no authority to enforce its conclusions and no disposition to suggest federal legislation or regulation. It acts as an unbiased coordinating agency, to formulate the results of its own and others' investigations and to give expression to the consensus of opinion of those best qualified to

express opinions on technical questions of great practical importance.

A second investigation (already alluded to) is in progress on the methods and instruments employed in testing gas for its heating value, its candlepower and its chemical purity, as well as in testing meters and measuring gas pressures. This will be embodied in a separate publication which will be frequently revised and kept up to date, in order to be as useful as possible to gas inspectors and engineers in determining whether gas meets the specifications under which it is sold.

A third investigation scarcely begun, but which is much needed and deserves extensive study, is on the safety and efficiency of gas appliances. Too many fatal accidents result from defective gas appliances, and the contamination of the atmosphere through imperfect combustion due to defective appliances is a serious matter, even when no fatalities result. This is a question in which cooperation of all the interests concerned can not fail to yield important results.

#### INVESTIGATIONS OF ELECTROLYSIS

Another important investigation carried out by the Bureau of Standards, which also concerns public-utility companies, is the damage by electrolysis produced by street railway currents flowing through the earth, upon gas and water pipes, lead-covered cables belonging to telephone, telegraph and electric-light companies, and the reinforced concrete foundations of buildings and bridges. Such insulated double conductor systems as those of New York, Washington and Cincinnati provide for the return of the current to the power houses without flowing through the earth, but most cities use the single overhead trolley, and permit the current to return in part through gas and water pipes and

other underground conductors. Where the current leaves such metal conductors, the latter are corroded electrolytically, and in some cases holes eaten through, thereby interfering with the service and involving expensive repairs. Many remedies have been proposed, but as yet comparatively little has been done to cure the evil. The bureau undertook a thorough study of the question for the purpose of testing some of the proposed remedies and arriving at a solution of the difficulty, if possible, that could be applied generally. This investigation is not yet completed, but already valuable results have been reached and it is hoped that shortly information will be made available for the use of the street railways that will permit them greatly to reduce the volume of the currents flowing through the earth without unreasonable expense, and that will enable the public-service commissions to deal more intelligently with the question. The problem is becoming each year more acute, since the volume of electric current used is each year increasing as the traffic increases, and the damage produced is therefore increasing at an increasing rate. Many lawsuits have arisen because of this damage, and such litigation is expensive because of the large amount of conflicting expert testimony adduced and the long time consumed in the trials. Money expended intelligently in solving the problem generally yields better returns than money spent in litigation.

In England and some continental countries there have been rules on this subject which have served as a guide to the electric railways in building their roadways, and hence they have been saved very largely from the evil effects of electrolysis, although at a somewhat increased first cost. In this country the subject was neglected for years. In the absence of public-service

commissions or similar bodies to establish regulations, and no government agency to take the lead in the investigation, the matter has been entirely neglected in many cases until the serious damage resulting has made the question a very acute one.

#### LIFE HAZARD IN ELECTRICAL WORK

Another question affecting public-utility companies is the life hazard in electrical work. There are altogether too many preventable fatalities due to high-potential electrical circuits, not only to employees of the electrical companies, but also to the public. In many cases such accidents could have been avoided if the companies had taken greater precautions, either by instructing their employees more carefully, or providing them with rubber gloves and other protective devices, or having repairs made only on dead lines, or using more substantial and more expensive construction, or running the high-potential transmission lines on private rights of way instead of on the highway, or keeping the dangerous wires away from telephone wires and on separate pole lines, or taking still other precautions which experience shows are necessary. The long-distance transmission of power is being resorted to more and more, and higher voltages are being used than a few years ago would have been thought possible. One thousand volts is a dangerous voltage, but transmission at fifty to a hundred thousand volts is becoming common. As water power is utilized more and more, the country will finally be covered with a network of high-potential transmission and distribution lines, and it is a matter of vital concern that all reasonable precautions be taken in the construction and operation of such lines. So long as public utilities were regarded as private business and a company was free to make as much money as

possible and invest as little as possible in its plant, the tendency was to economize unduly with respect to protective devices, and any construction that was more expensive than the mechanical or electrical requirements demanded was avoided. But when we regard railroads, electric light and power companies and telephone and telegraph companies not only as public utilities, but as quasi-public institutions, and permit them to charge enough to make a good profit, but to make the rates as low as good service permits, then it is seen that the public pays for the cost of protection, and it is entitled to require that every reasonable precaution be taken to safeguard human life. This latter is the view which is now becoming general, and the public-service commissions are therefore greatly interested in having rules and regulations worked out in such a way as to be capable of enforcement upon the electrical companies. On the other hand, the electrical companies themselves are anxious for such information. It is not necessary to make original investigations in every case; it is often a question of collecting and digesting the information already in existence, and with the cooperation of numerous agencies which stand ready to assist, work out a body of rules and regulations that will be as useful as possible. Congress has recently made a special appropriation to permit the bureau to undertake such a study of the life hazard in electrical work, and it is hoped that valuable results may be accomplished.

#### RAILROAD SCALES

Another investigation of great practical importance, in which the Interstate Commerce Commission and the Bureau of Standards are cooperating, is the investigation of the accuracy of railroad scales, especially car scales, for weighing freight.

Freights to the amount of two thousand millions of dollars are annually collected by the railroads on weighings made with scales, most of which are seldom tested and, except in three western states, never officially inspected. Numerous disputes and complaints could be avoided if the scales were officially tested and certified, and if provision were made for retesting on complaint. Certainly, it is as important to test large scales as small ones, and the cost of doing so is trifling in comparison with the enormous interests at stake.

#### LOCOMOTIVE HEADLIGHTS

Another subject with which some of the state commissions have dealt is the kind of headlights used on locomotives, their candlepower and reliability. In some states legislation has been enacted requiring a particular kind of headlight. It has been charged that such legislation in some cases has been inspired by commercial interests. In one state the commission issued a rule requiring a certain candlepower, but not specifying how it was to be measured or exactly what was meant. The railroads, contending that the order was ambiguous, impossible to comply with by one interpretation and undesirable by another interpretation, appealed to the courts. After a lengthy and expensive litigation the order of the commission was set aside. This case is cited to illustrate the need of technical information by state commissions before issuing mandatory orders, and also the hardship to railroads or other public-utility companies to be obliged to contest in the courts orders that work a hardship and which would not have been issued if full information had been at hand. There is great need of further investigation of the subject of headlights for use on steam and electric railways, to determine the best service that

different types are capable of giving, and to formulate rules that could be enforced by the commissions. Some railroads economize unduly on the maintenance of headlights; in the interest of safety to the public, wise regulations should be in effect.

#### CAR LIGHTING

The lighting of cars (both steam and electric) is another practical matter that has not received the attention that it deserves. Most people read more or less on trains and street cars, and with many who ride a long distance to and from business this is their best time for reading. As a rule, however, the lighting of cars is insufficient and the arrangement of lights is often atrocious from the point of view both of the passengers who are not reading and those who are. Eyesight is too precious a possession and too easily injured to justify the continuance of poor lighting of cars. Better light is required than would be necessary if the cars were not moving. The problem is different on electric cars from what it is on steam cars, because in the former the current for lights comes from the same circuit that supplies the motors, and hence great variations occur due to the fluctuating voltage on the trolley wire. To secure better lighting, (1) a steadier voltage should be available, (2) better lamps should be used than are generally seen in electric cars, (3) a greater quantity of light should be available and (4) the lamps should be so shaded and so located as to keep the glare out of the eyes of the passenger, and yet give good illumination for reading. The immense importance of this subject can only be realized when one considers the millions of people who daily spend considerable time in steam or electric cars, and how much better the service would be if the cars were pleasantly and sufficiently lighted. The

public-service commissions have it in their power to effect an immense improvement in this respect, but first a thorough investigation should be made, with the cooperation of the railroads, to show what are the best methods to follow, and what it is practicable to accomplish with present resources.

#### HEATING AND VENTILATION OF CARS

Another question of great practical importance is the heating and ventilation of cars, including Pullman sleeping-cars. Any person who has sweltered in an overheated, unventilated lower berth of a sleeping-car (and who has not), will allow that there is great room for improvement. Surely the resources of American invention have not been exhausted in this direction, nor, indeed, with respect to heating and ventilation of day coaches. It is one of the functions of public-service commissions to see that the health and comfort of the public are kept in view by the utility companies, and if it can be made clear what should be done in this respect, the way to reform is open.

#### RAILWAY ACCIDENTS

Another line of work which deserves an immense amount of investigation and study, and cooperation between the states and the federal government, is the prevention of railway accidents. Much has been done and is now being done, both by federal and state agencies, and by the railway companies; but far greater sums of money might well be expended by the states and the federal government in a systematic investigation of all phases of this question. It is nothing short of a national disgrace that American railways should kill and injure so many more people than do the railways of European countries, even where the speeds are as high and the pas-

senger traffic as heavy. Life is too cheap with us, and the penalty for disasters too slight. The causes of these accidents are partly physical and partly psychological; no doubt greater attention given to the subject of how to prevent both kinds of accidents would be abundantly rewarded.<sup>5</sup>

Other subjects deserving research could be named that fall within the province of the public-service commission, but enough has been said to show how important are their functions apart from the duty of fixing rates and preventing discrimination. These illustrations show how much better it is for the public as well as the companies that the commissions regulate by cooperating with and assisting the companies instead merely of dictating to them what they shall do or shall not do; that the scientist, the engineer and the statistician are more useful to them in their work than the lawyer; that the bar of public opinion is more effective than the courts in enforcing their decrees. Many of these utilities are operated by big corporations, owning scores of plants in many states; in the case of the telephone and telegraph, they are gigantic systems operating over the whole country. It is therefore important that the rules and regulations in the different states shall be as nearly uniform as possible. Hence, in order to reach wise and just conclusions, and to secure uniformity,

<sup>5</sup> A recent writer states that 19,377 more persons were injured on railroads in the United States in 1912 than in 1911, and commenting on the slight amount of scientific information that has been collected regarding the causes of accidents, he adds:

"The railroads of this country carry so many passengers and so much freight that in one year they are able to charge three billion dollars for the service. And yet it is admitted that no accurate engineering data showing the actual stresses which are set up in railway structures by locomotives and cars of different weights and moving at different speeds has ever been gathered."

it is important that the states cooperate with one another, and the federal government can serve as a valuable aid and co-ordinating force in this cooperation.

The results that are being attained in this way are only beginning to be realized. They will be of invaluable benefit, not only to the public served, but to the companies themselves, and to the cause of good government. With the utility companies under the control of business-like state commissions, the business is better managed,<sup>6</sup> discriminations in rates are eliminated,<sup>7</sup> the utilities are taken out of local politics and the possibility of pure municipal government in America is enormously enhanced.<sup>8</sup>

\* B. H. Meyer, speaking on the Wisconsin Public Utilities Commission at the Pittsburgh meeting (1908) of the National Municipal League, said:

"The utility law is working a revolution in business management. . . . Many of the utility companies have not been operated on a business basis; in fact, it is probable that a good many of the managements did not have the remotest idea as to the exact standing, from a business point of view, of the plant they were operating. Uniform accounting and rules governing the service and the regulation of rates, compel the adoption of business and scientific methods. This is resulting in nothing short of a revolution in management."

<sup>7</sup> The whole state of Wisconsin was literally streaked and plastered with discrimination in the rates of utilities, and in all the rest of the country, where the extent of the discriminations have not yet been determined, as they have been in Wisconsin, it is quite probable that discriminations similar in character and extent likewise exist.

<sup>8</sup> Governor McGovern has this to say regarding the utilities and politics in Wisconsin:

"Times were in Wisconsin when the railroads ran or tried to run the government of the state, and the minor utilities sought to boss the cities, towns and even villages. They contributed liberally to campaign funds, urged their supporters and lobbyists to become candidates for public office, and in close election districts colonized voters in the old conventional way. Now, one and all, they are in this sense absolutely out of politics. There is, indeed, no reason now why public-

One of the best results of the method of regulation by public-service commissions is the publicity it secures of the affairs of the company and the confidence it establishes in the public mind in the various utility companies. The suspicion and distrust which Senator Root emphasized so strongly in his New York address is everywhere felt toward these companies when their affairs are kept secret, and especially when the service is poor and the dividends good. Controversies arise which sometimes degenerate into bitter and partisan feuds. Who can feel kindly toward the management of a street railway company if he is usually compelled to ride as a strap-hanger, or toward a gas company if the rates are excessive or he believes that his meter races, or toward any company that appears to regard its franchise as the deed to a private monopoly. If the service is improved or the rates reduced as the business grows more prosperous, the people as well as the stockholders derive benefits from success. The public soon realizes that utilities so conducted are in effect partnerships between the public and the stockholders, and are willing that the latter receive increased dividends with increased prosperity if the public is permitted to share the fruits of success. The sliding scale of prices for gas is a successful example of this system, but it is also realized in many cases where a sliding scale of prices has not been fixed in advance. The regulation of prices by a commission gives

service corporations in Wisconsin should wish to dabble in public affairs. Their relations to the people of the state have been definitely and finally determined. They no longer have anything to gain or lose by intermeddling in politics, and apparently they have decided to retire for good. What the elimination of public-service corporations from participation in political campaigns signifies in the purification of public life, no one here needs to be reminded."

in effect a sliding scale, by which either the price goes down or the quality of the service goes up, as the success of the business justifies it. For want of a public-service commission in the District of Columbia, the Interstate Commerce Commission has recently been exercising the functions of such a commission with respect to the street railways, and with good effect. There is great need of a full-fledged public-service commission in the district, and it is hoped that Congress in its wisdom will respond to public sentiment and establish such a commission.<sup>9</sup>

How infinitely better is this method of regulation than the building of publicly-owned utilities to compete with private plants already in existence. For a state or city to say that it is impotent to regulate a public utility is a confession of weakness; but there is far greater difficulty in city control than in regulation by state commissions. Except, perhaps, in the largest cities, it seems much better to have strong state commissions, well equipped with technical assistants, than to have separate commissions for each city. And with the cooperation of other states and the federal government, any state commission can establish its work with only a fraction of the effort and expense required by those states that have pioneered the movement.<sup>10</sup>

Turning now to the great industrial and financial corporations popularly called trusts, the question suggests itself whether it is possible for the government to regulate them in a manner similar to the regulation of the natural monopolies we have

been discussing, so that full publicity may be secured, the rights of the public may be conserved, and at the same time the rank and file of the stockholders will be protected from the vultures that often hover over the executive offices of such concerns. One can not say that it will be done as easily, but it is coming to be believed that the general method adopted in the regulation of public utilities is the right one, namely, less dependence on law and the courts, and more dependence on engineers, statisticians and business experts; that the government should prescribe affirmative duties for the giant corporations, and not merely negative ones; that a constructive policy that would benefit both the business concerns and the public they serve should be sought, rather than a retrograde policy that is no benefit to the business and does no good to the public. If such regulation could be realized, and consolidations and promotions in business could be limited to such as would benefit both the public and the stockholders, and not merely big financiers and promoters, it would be a notable achievement in our political as well as economic history. It would assist mightily in the peaceful settlement of industrial disputes and in the bringing about of a better understanding between capital and labor.

It is just as reasonable to expect the government to perform this function of regulation of monopolies as to expect it to adjust international disputes by arbitration rather than by war. It is not socialistic, but rather the reverse, for it is the alternative of state ownership. In Germany the cities are great business concerns operated by business men for the benefit of the people, and as such they are models for the whole world. They own and operate most of the public utilities themselves, and do it well, and hence the necessity of public regulation is there less

<sup>9</sup> A public-utility commission for the District of Columbia has been established by Congress since this address was delivered.

<sup>10</sup> Writing in 1908, Professor Ely said: "States having commissions empowered to enforce uniform accounting will constitute great economic laboratories in this connection during the next quarter of a century."

felt, although it has been practised for many years. But in this country, municipal ownership has been less successful, except in the case of municipal water supplies.

There have been three stages in the modern history of natural monopolies. In the first they went unregulated, being operated for the profit of the owners and exploited for the benefit of financiers. In the second stage, regulation was by legislation and lawsuit. In the third, regulation is by commission; the regulation is more complete, as well as more intelligent, and co-operation and publicity are keynotes of the method.

The large industrial corporations which have virtual monopolies, are mainly in the first stage, although some are in the second. Whether they will finally come to the third stage, and be regulated by the methods now applied so successfully to natural monopolies, remains for the future to determine.

If state regulation of natural monopolies becomes as general within a few years as it promises to be, and if it is as successful generally as it has been in the few states which took it up first, it will solve the problem of public utilities and largely solve the problem also of good municipal government.

The signal success of the Wisconsin Commission was largely due to the influence of the University of Wisconsin. In its personnel and methods it was a scientific commission, and entered into its work with the spirit of investigators. Its spirit and its methods have been adopted by some of the other state commissions, of which a large number have been created recently and are now taking up their work.

If the administrative officers of the commissions are assisted by scientists, engineers and economists, and the work is done in a judicial spirit, as new problems being

taken up as a scientific research would be, the states and federal government acting in full cooperation, with the experience of each available to all—if the work is done in that way we may be certain that success will be sure and permanent.

EDWARD B. ROSA

BUREAU OF STANDARDS

#### *THE NINTH INTERNATIONAL CONGRESS OF ZOOLOGY AT MONACO*

UNDER the presidency of Prince Albert I. of Monaco, the congress was formally opened in the beautiful Museum of Oceanography on March 25. In his opening address the prince, after referring to the basic importance of the study of marine life and the conditions under which it exists, for one who desires a reasonable conception of the problems of biology, spoke of the prime value of the study of zoology as an aid in the solution of many of the problems confronting human social groups. He very cleverly pointed to the Principality of Monaco as a community where the life of the people is illumined by the light of science, and where the climax of all the activities of the state is a noble scientific institution devoted, not only to the investigation of the deep sea and its life, but to the application of the facts thus discovered to the daily life of the people.

For the reading of papers the congress was organized into eight sections, which, with the number of titles on the program of each, were as follows:

- I. Comparative Anatomy and Physiology. 32 titles.
- II. Cytology. General Embryology. Protistology. 25 titles.
- III. Systematic Zoology. Behavior. 26 titles.
- IV. General Zoology. Paleozoology. Zoogeography. 13 titles.
- V. Oceanic Biology. Plankton. 8 titles.
- VI. Applied Zoology. Parasitology. Museums. 15 titles.
- VII. Nomenclature. 9 titles.
- Sub-Section VIII. Entomology. 10 titles.

Three general sessions were held, upon the

programs of which there were thirteen additional titles.

An American zoologist could not fail to be struck with the relatively small number of titles lying in the experimental phases of zoology, and so complete has become the divorce between continental zoology and genetics that the program of the congress contained but two titles within the latter field.

The topic subtending the widest angle, both in informal discussion and in the business of the congress, was that of nomenclature, more specifically, the advisability of continuing the application of the rule of priority adopted by the International Commission on Nomenclature. This question was discussed first in the section on nomenclature, where the opinions of American zoologists were presented chiefly by Dr. Stiles, Professor Williston and Dr. Field. The section first resolved to recommend to the congress the proposal of Dr. Field, that an author might, in special instances, present to the commission a request that a name be established although not in accordance with the strict priority rule. Such cases were to be transmitted to a sub-committee of specialists and to be published before their adoption. If the commission were unable to accept the decision of the sub-committee, an appeal might then be had to the congress at its next meeting.

Later, however, the section on nomenclature reversed this action and made a recommendation which was finally presented to the congress and adopted by a large majority. A precise statement of this action will doubtless be published later, but in substance it is as follows. The International Commission on Nomenclature is given full power to suspend the rules of nomenclature, including that of priority, in special cases presented to it by authors, with the understanding that the commission will confer with specialists in the groups concerned before coming to a decision. If then, the vote of the commission should be unanimous, the suspension of

the rule in that case becomes effective immediately; if two thirds of the commission favor the suspension, the question is to be laid before a special committee of three, to be appointed by the president of the section on nomenclature, at the subsequent meeting of the congress, this committee to consist of one member favoring the suspension, one opposed to it, and a third, whose opinion has not been formed.

The result of this action is primarily to free the commission from the obligation of a strict adherence to the application of the priority rule. Whether this action will permit a reasonable flexibility in the interpretation of the rules of nomenclature, of course remains to be seen. To many it seems regrettable that so much of the time and work of these congresses must be devoted to the discussion of so special a topic, and one so indirectly related to the advancement of zoological knowledge.

At the last general session on March 29, the award of the Emperor Nicolas II. prize was made to Professor Ernst Bresslau, Strassburg, for his work on the mammary organs of the lower mammals, and to Professor Th. Mortensen, Copenhagen, for his investigations of the invertebrates of the Arctic oceans. The O. Kowalewsky prize was awarded to Professor Paul Pelseneer, Gand, for his well-known work on the phylogeny of the Mollusca. At this meeting Budapest was selected as the place of the tenth congress, in 1916, and Professor G. Horvath, of the Hungarian National Museum was elected president of that congress.

The social events of the congress were especially brilliant, thanks to the hospitality of Prince Albert I., and these added to the wonderful natural beauties and charms of Monaco, combined to render the congress a memorable occasion.

The congress was very largely attended, the enrollment of members reaching approximately seven hundred, a considerable number of whom were, however, not able actually to be in attendance. While the date of the ses-

sion was particularly favorable for European members, a general attendance of American zoologists was practically impossible.

Following is a list of the members present from North America:

Dr. J. A. Allen, American Museum of Natural History. "Individual variation in musk oxen."

Mr. E. Phelps Allis, Menton.

Professor and Mrs. Ulric Dahlgren, Princeton University. (a) "A remarkable polarity in the motor nerve cells of the electric apparatus of *Tetronarce occidentalis*." (b) "Embryonic history of the electric apparatus in *Gymnarchus niloticus*."

Dr. and Mrs. H. H. Field, Concilium Bibliographicum, Zurich.

Miss Katherine Foot, New York City. "Results of crossing three Hemiptera species with reference to the inheritance of an exclusively male character" (with Miss Strobell).

Professor F. H. Herrick, Western Reserve University.

Professor and Mrs. W. E. Kellicott, Goucher College.

Dr. and Mrs. Leonard Stejneger, Smithsonian Institution.

Dr. and Mrs. C. W. Stiles, U. S. Bureau of Public Health. "The distribution of *Necator americanus* in the United States, its medical and economic importance and the campaign for its eradication."

Miss E. C. Strobell, New York City.

Professor S. W. Williston, Chicago University. (a) "The Amphibia and Reptilia of the American Permo-Carboniferous." (b) Communication on "Nomenclature."

Professor and Mrs. R. Ramsey Wright, University of Toronto.

WM. E. KELLICOTT

#### THE TARR MEMORIAL WINDOW

ON March 23, 1913, a memorial window, by Tiffany, was unveiled in Sage Chapel of Cornell University. It was given by Mrs. Tarr and accepted, for the university, by acting president T. F. Crane. The presentation and description of the window, by Lawrence Martin, follows.

This memorial window, dedicated to the late Ralph Stockman Tarr, is given by Mrs. Tarr to Cornell University. Thus the present and

future generations of Cornell students and of worshipers in this chapel will be reminded of one who was a faithful and inspiring teacher and a great scientist. During the score of years through which he was professor of dynamic geology and physical geography at Cornell University he made a deep impression upon the minds and in the hearts of those of us who were so fortunate as to come in contact with him in the home, in the lecture room or laboratory, or in God's great outdoors.

The memory of Professor Tarr is fresh with all of those present. It is just a year since we were gathered here to pay our last respects at his funeral. Upon this Easter afternoon and in presenting this memorial window I may perhaps be permitted to say briefly some of the things with which all our hearts are filled.

Professor Tarr's life was a wonderful example to young men. I may speak of his determination to get an education, a determination which led him to enter Harvard University and to work his way through college, and, in the early years, even to travel sixty miles each day to and from his recitations while he lived at his parents' home.

I may speak of his hard work while he was a professor at Cornell, sparing no pains to make his lectures and his laboratory and field work clear, interesting, disciplinary and scientifically sound. The hundreds of students who have taken Professor Tarr's courses are the best fruits of this work, for none of them but gained with their knowledge of geology and physical geography a sense of admiration and affection for the teacher.

I may speak of the imparting of his knowledge of the facts of geography to the hundreds of thousands of readers of his books—books which were written with the utmost regard for truth and for the upbuilding of character by the example gained in learning how one's fellow men are utilizing the great resources of the earth and adapting themselves to the diverse environments in which the Almighty has placed them.

I may speak of his years of investigation. Professor Tarr was always a student. The success of his teaching and of his writing of

books depended largely upon the almost incessant travel in which his summer vacations and sabbatical years were spent. In every state in the union, in most of the countries of Europe, in the West Indies and Central America, in Greenland, in Spitzbergen, in Alaska, Professor Tarr studied. For he traveled not as a sightseer but as a student, as one who would learn the secrets of nature that he might impart them to others. Work and service. These were the keynotes of his life.

The window which has just been unveiled on the south side of Sage Chapel is typical of Professor Tarr's life of work and service. It represents the valley of a river. In the background rise the mountains, capped by the eternal snows, perhaps containing, in their valleys, glaciers such as Professor Tarr made his especial study. Here is the source of the river, which flows steadily because it is fed by the rain and by the melting snow of the mountains, the pure snow which typifies the innocence of youth.

In the middle distance the river is flowing through a broad, open valley, a valley which has been made by the river itself, a valley which, by the erosive action of the stream, is being made broader and therefore more suitable for habitation by man. The river must widen and deepen its valley, it must carry away the material which is here an encumbrance, but which the river will later deposit on the lower land where it will be of most use to man.

In the foreground the river is in a narrow gorge. This stream has encountered a temporary obstacle in its course. To remove this it uses the very material which it is carrying forward to the sea. Soon it will widen the gorge into an open valley like that of the middle distance. Work is necessary in accomplishing this, hard work in order that the valley may have gently-sloping walls upon which man may plant his fields and in order that the stream bed may slope gently so that the river may do its service in carrying the products of the fields to the markets and towns.

Now most rivers also have lower courses,

places where there are broad floodplains and deltas, where the river has deposited rich soil, carried down from the mountains, where the river flows slowly, its hard work nearly done. As in the life of rivers with hurried course and hardest tasks in the youthful section near the mountains, and leisurely current and little work near the mouth, where the river terminates in the all-embracing ocean, so with man. Only in the case of Professor Tarr the river which typifies his life shows no leisurely old age. You will recall that he died on March 21, 1912, at the age of forty-eight. His was a life of hard work, of toil and service. But although he was not permitted to enjoy the years of less strenuous labor, the effort was not in vain. We, his relatives and friends and students, will profit largely, throughout the years to come, by the work which he has placed at our service.

May this memorial window which I now, on behalf of Mrs. Tarr, present to Cornell University ever recall the memory of the work and service to others that was performed here by Ralph Stockman Tarr.

---

#### SCIENTIFIC NOTES AND NEWS

At the semi-centennial celebration of the National Academy of Sciences to be held next week, the medals and prizes of the academy will be presented by the president of the United States. The first award of the Comstock prize, of the value of \$1,500, will be to Professor R. A. Millikan, of the University of Chicago, for his researches on the charge of the electron, the ratio of electric charge to mass and gaseous ionization. The Henry Draper medal has been awarded to M. Henri Deslandres, director of the Astrophysical Observatory at Meudon, for his researches in solar and stellar physics.

THE Henry Phipps Psychiatric Clinic, of the Johns Hopkins Hospital, established and erected by Mr. Henry Phipps, of New York, to promote the study of mental disease and its early treatment, was dedicated on April 16, and the exercises will continue during the two following days. Addressees were announced

by Sir William Osler, Professor W. MacDougall, Professor E. Bleuler, Dr. F. W. Mott, Professor O. Rossi, Professor Heilbronner, Dr. Achucarro and a number of leading American psychiatrists, including Professor A. Meyer, the director of the clinic.

THE first lecture on the Joseph Leidy Memorial Foundation was delivered at the University of Pennsylvania on April 17 by Professor Edmund Beecher Wilson, Columbia University. A tribute was paid, on this occasion, to the life and services of Joseph Leidy, the student, teacher and investigator, by Professor Charles Sedgwick Minot, Harvard University.

A MEETING in commemoration of the life and work of the late Dr. John Shaw Billings, late director of the New York Public Library, will be held in the library building on April 25.

KING VICTOR EMMANUEL presided on March 27 at the inauguration of the International Geographical Congress, Rome.

THE National Geographic Society has voted \$20,000 to the Norwegian Polar Expedition, which will leave the Pacific coast under command of Captain Roald Amundsen in June, 1914, to explore the polar basin. The voyage, it is expected, will require four years' drifting in the polar ice.

DR. DAVID SHARP, Lawnside, Brockenhurst, Hants, England, and Dr. J. H. Fabre, Serignan, Vancluse, France, were chosen on April 3 as the first two honorary members of the Entomological Society of Washington. The Entomological Society of Washington may elect ten honorary members from among foreign entomologists.

WE regret to learn that Professor Willet M. Hays, assistant secretary of agriculture, under the Roosevelt and Taft administrations and formerly professor of agriculture in the University of Minnesota, is suffering a serious nervous breakdown and is taking treatment at a sanitarium near Washington. Professor Hays had recently accepted a commission from the government of Argentina to reorganize the rural educational system of that

republic, but his illness will make it impossible to assume the duties.

DR. L. A. BAUER sails from New York on April 22, to be gone for about two months, in order to arrange for cooperative magnetic work between the Department of Terrestrial Magnetism and various foreign institutions. On May 22 he will deliver the Halley lecture on "Terrestrial Magnetism" at the University of Oxford.

PROFESSOR H. T. BARNES, of McGill University, will accompany the government steamer *Montcalme* to patrol the entrance of the Gulf of St. Lawrence, to report the presence of icebergs. Professor Barnes will use his microthermometer to detect the presence of ice.

PROFESSOR H. T. FERNALD, of the Massachusetts Agricultural College, sails for Europe the last of April, for study in various European museums. He will return about the middle of September.

A JAPANESE translation of "The Elements of Statistics," by Wilford I. King, of the economics department of the University of Wisconsin, has been made. The book has just passed through its second English edition.

DR. LAFAYETTE B. MENDEL, professor of physiological chemistry in the Sheffield Scientific School of Yale University, addressed the students of the Pratt Institute in Brooklyn, on April 11 on "Nutrition and Growth."

ON April 7, before the Southern California Academy of Sciences, Los Angeles, Dr. D. T. MacDougall, director of the department of botanical research of the Carnegie Institution, delivered an address on "Some Physical and Biological Features of American Deserts."

DR. H. L. FAIRCHILD, professor of geology in the University of Rochester, delivered a lecture at Syracuse University under the auspices of the Syracuse Chapter of Sigma Xi, on the evening of April 11. He took for his subject "Remarkable Glacial Drainage Features about Syracuse."

PRESIDENT CHARLES R. VAN HISE, of the University of Wisconsin, delivered an address on "Waste in Distribution" before the first

National Conference on Marketing and Farm Credits, held in Chicago on April 8.

THE New York Academy of Sciences will hold a reception on April 21, when an illustrated lecture will be given by Professor Bergen Davis, of Columbia University, on "Electricity as Revealed by its Passage through Gases." The lecture will be followed by a reception.

OSCAR DANA ALLEN, whose death has been noted in *SCIENCE*, was born in Maine in 1836. In 1871 he was elected professor of metallurgy in the Sheffield Scientific School of Yale University. In 1874 he was also made professor of analytical chemistry. Prolonged ill health obliged him to resign these two positions in 1887, when he moved to California for four years. After that he lived at what is now called Ashford, a remote place situated at the base of Mount Ranier in Washington. There he devoted himself to horticulture, botany and biology, making the flora of the mountain near which he lived his special study.

DR. BELA LENGYEL, professor of chemistry at Budapest, has died at the age of fifty-nine years.

DR. EDUARD SCHMITT, formerly professor of engineering in the Darmstadt Technical School, has died at the age of seventy-one years.

A SITE of about seven acres, in the District of Columbia and near Rock Creek Park, has been purchased by the Carnegie Institution of Washington to provide the necessary facilities for the office and experimental work of the Department of Terrestrial Magnetism. The building to be erected is to embrace the office, laboratory and instrument shop; according to present expectations, it will be ready for occupancy early in 1914.

THE magnetic survey yacht *Carnegie* left St. Helena on April 9, bound for Bahia, and is expected to return to her home port at the end of the year, thus completing the three years' circumnavigation cruise. On the trip from Coronel, Chile, to Port Stanley, Falkland Islands, made in December and January last, she encountered an exceptionally smooth

passage in rounding the Horn. However, on her run from the Falkland Islands to St. Helena, February 22 to April 3, twenty-three icebergs were sighted. The vessel is in command, as heretofore, of Mr. W. J. Peters.

THE annual report of the National Academy of Sciences shows that appropriations from the Bache fund amounting to \$2,000 were made as follows:

J. A. Parkhurst, Yerkes Observatory, Williams Bay, Wis., for the determination by photographic methods of the visual and photographic magnitudes and the spectral types of faint stars, \$500.

M. A. Rosanoff, Clark University, Worcester, Mass., for the determination of the several factors that influence the velocity of sugar hydrolysis, \$500.

S. C. Chandler, Wellesley Hills, Mass., for the definitive discussion of the latitude variation from 1725 to the present time, \$350.

F. B. Sumner, additional grant for the continuation of experiments on the effects of external conditions on growing white mice, \$150.

T. A. Mann, Concord, N. H., for the determination of the cause and mode of spread of septic sore throat, \$100.

S. F. Acree, Johns Hopkins University, Baltimore, Md., for the completion of the study of the action of alkyl halides on sodium phenolate, \$500.

E. H. Hall, Harvard University, for the study of the electromagnetic and thermomagnetic behavior of metals, \$500.

ONE of the last official acts of President Taft was the signing of a proclamation eliminating 41,150 acres from the Kansas National Forest. The tract eliminated is in the extreme western section of the forest, and includes all that part which lies west of the fifth guide meridian. It is principally a sandhill country and while it could be reforested, there is such a large proportion of alienated or privately owned land within the forest boundaries that the government's reforestation work would have to be confined to more or less isolated areas. Since the area is valuable for grazing, its restoration to the public domain was deemed advisable. At the same time that the land was eliminated from the forest it was withdrawn from entry, under the authority which congress has given the

president to withdraw land from all forms of entry except as to mineral claims for the development of metalliferous ores. The land will be restored to settlement and entry after such advertisement in the local papers as the secretary of the interior may consider necessary. The Forest Service is successfully reforesting a considerable area in the sandhills of Nebraska and Kansas, where the soil is so loose in texture that it blows away as soon as it is cultivated. Therefore, according to the government's foresters, the problem has been to grow trees in competition with the native grasses, both making rival demands on the small amount of moisture. If the grass cover is removed the soil blows out completely and exposes the roots of the trees. The success already attained indicates, in the judgment of the government foresters, that a large part of the sandhill country will become timber-producing.

The quantity of briquetted fuel manufactured in the United States in 1912 showed a small gain over the output for 1911, and according to E. W. Parker, of the United States Geological Survey, the briquet industry may be considered as now passing out of the experimental stage and assuming a more substantial and permanent character. The quantity of briquetted fuel made in 1912, at 19 plants, was 220,064 short tons, valued at \$952,261, as compared with 218,443 tons valued at \$808,721 in 1911. Of these plants 7 used anthracite culm, 9 used bituminous or semi-bituminous slack, 1 used residue from gas manufactured from oil, 1 used mixed anthracite culm and bituminous slack, and 1 used peat. The largest producer of briquets in the United States in 1912 was the Berwind Fuel Company, of Superior, Wis., the output of which was a little in excess of 50,000 short tons. The quantity of raw material available for the manufacture of briquets, as stated by Mr. Parker, is ample and may be obtained at slight cost. The most desirable material for producing a smokeless product is anthracite culm, a plentiful supply of which still remains in the anthracite region of Pennsylvania and more is produced daily in the mining opera-

tions. It is not too much to believe or to hope that in the near future the small sizes of anthracite, such as buckwheat and smaller, that are now sold for making steam, in competition with bituminous coal and at prices below the actual cost of production, will become more valuable as a raw material for the briquet manufacturer. The output of these small sizes, produced by breaking up large coal to obtain the domestic grades—egg, stove and nut—exceeds 20,000,000 long tons annually, exclusive of 3,000,000 to 4,000,000 tons annually recovered from the culm banks by washeries. The present revenue from this product will not exceed \$30,000,000. Washery and small size coal is worth from 50 cents to \$1.50 a ton, the price depending on the size. As briquetted fuel it should be worth as much as stove or egg coal, or \$3 to \$4 per ton. The cost of briquetting is \$1 to \$1.25 per ton. The uniform size of the briquets makes them desirable as a domestic fuel; besides if properly made they are completely consumed and do not produce clinkers.

#### UNIVERSITY AND EDUCATIONAL NEWS

PRINCETON UNIVERSITY has received three gifts: \$100,000 from Mr. and Mrs. Russell W. Moore, of New York City, to endow a professorship of chemistry; \$125,000 given anonymously for a professorship not named, and \$30,000 from Mr. John D. Cadawallader, of New York City. About \$70,000 were received for current expenses.

THE decision of the jury in the case of the will of Mr. C. H. Pratt being in its favor, the Massachusetts Institute of Technology will receive the bequest, amounting to three quarters of a million dollars, to be devoted to the establishment of a Pratt School of Naval Architecture and Marine Engineering. The requirement that the money actually in hand shall be held by the trustees till it amounts to the specified sum will not cause any delay, since the estate has proved to be of such value as to lack only a few thousand dollars, and will be of the requisite amount by the time the institute is ready to use it.

WHITALL HALL, of Haverford College, which houses the scientific departments, was damaged by fire on April 8, with a loss estimated at \$20,000.

THE board of trustees has approved plans for an addition to the Women's School of the Carnegie Institute of Technology.

NEW buildings of the Sorbonne, Paris, have been erected at a cost of 782,000 francs. They are the Curie laboratory, under the direction of Mme. Curie; the radium laboratory, under the direction of M. Debiere, and the Pasteur laboratory, under the direction of M. Regnaud.

PROFESSOR ALEXANDER SMITH, administrative head of the department of chemistry in Columbia University, has accepted the position of professor of chemistry on the Wyman Foundation in Princeton University, and the headship of the department of chemistry. By the desire of the authorities of Columbia University, as well as his own, he will complete three years of service with Columbia University and will accept this call to take effect at the end of the academic year 1913-14.

DR. WILLIAM TRELEASE, director of the Missouri Botanical Garden from 1889 to 1912, has accepted the position of professor of botany and head of the department of botany at the University of Illinois.

#### DISCUSSION AND CORRESPONDENCE

##### ON METHODS OF TEACHING MODERN LANGUAGES

THE basis and warrant of all language teaching must be psychological. But among all the multitudinous articles and books on the subject, there are only a very few which take cognizance of the psychology of language teaching, although, to be sure, the practical application of the principles is practised in part, consciously or unconsciously.

The test of any method must be psychological. Here mere practical results can not be the criterion. The question should not be: Has the learner acquired so and so much of a vocabulary? but rather it should be: Has the learner been acquiring good *mental habits* while he has been acquiring the vocabulary? That is to say, the method must be based upon

sound laws of the mind, to follow which means to produce good *habits of study*.

1. The newer school of linguists are agreed that language is an activity of the mind; not a thing thrust upon the individual, but rather the outward manifestation of mental states.

Speech without ideas is useless. Adults do not naturally learn words for the sake of learning them, but only for the purpose of expressing ideas. We find in normal adults first the idea, then the expression of it, or possibly the two simultaneously, but not the reverse.

2. Physiological psychology teaches us that four distinct centers of the brain are active in the acquisition of language; namely: the auditory, the visual, the motor writing, and the motor speech centers, the first two sensory, the latter two motor.<sup>1</sup> The function of the auditory center is to receive sensory impressions through the nerves of the ear; that of the visual center to receive impressions from the nerves of the eye; the motor-writing center controls the muscles of the hand in writing, while the motor speech center controls the muscles of the speech organs.

It has been established, also, by experimentation that the strength of the sensory impressions upon these centers varies with different individuals. There are those who get stronger impressions by the auditory than by the visual center, and more facile expression by the motor-speech than by the motor-writing center, and *vice versa*.

Moreover, there are in the case of the four brain centers under discussion not only nerve currents from the end-organs to the centers and from the motor centers to the muscles, there are also the association areas of the brain which serve communication between these centers, thereby bringing about a lively interaction between them.

3. Without going into the old question whether sensation is the sole principle of knowledge, we are on safe ground psycholog-

<sup>1</sup> Cf. Wundt, Wilhelm, "Principles of Physiological Psychology," English translation, London and New York, 1904, pp. 302 ff.; Judd, C. H., "Psychology, General Introduction," New York, 1907, pp. 51 ff.

ically when we assert that in learning a language auditory, visual and kinesthetic sensations play the most important rôle, and are in fact the basis of knowledge. It follows then that the greater the number of sensory impressions that can be enlisted in the acquisition of language, the greater the acquisition. It follows also that the more combined the activity of the senses, the more rapid and the more thorough will be the organization of the speech centers physically and psychically.

4. From perceiving sensations, that is, from percepts, the mind proceeds, by discriminating, comparing, judging from knowns to unknowns, to form concepts.

5. Retentivity depends for its strength upon the strength of the original impression and upon the frequency of repetition. It shows greatest virility in the retention of linguistic forms when the four speech centers operate to heighten the intensity of the impression.

6. Beyond this there is the ideal of persistence which is strengthened by resolutely overcoming obstacles, *e. g.*, by mastering assigned tasks of difficulty sufficient to form a real obstacle to their consummation.

What do these facts mean to the teacher of language, and how should pedagogy make use of them?

1. It is unnatural and hence poor pedagogy to teach isolated words, and to proceed from the parts to the whole; that is, here, from the isolated vocables to the sentence, the judgment. The reverse: from a consideration of the whole sentence to a consideration of the parts is the law of nature, and is a good psychological principle.

Thus the argument which is often used against the analytical or direct method that adults do not learn language like children does much of its force. Certain it is that for adults the idea comes before the sign for the idea, although, to be sure, the mature mind, accustomed to abstract thinking, soon demands that it be given not only the percepts but the concepts, and the general concepts as well.

2. Good pedagogy should call into activity

all the powers of the mind of the learner. Thus in the case of the language teacher, to utilize the visual and the graphic centers only, and allow the auditory and the motor speech centers to lie barren, is to get only a portion of the sensory impression that may be got if all the centers are utilized.

Again, since some individuals of a group will learn better by the utilization of the visual and the graphic centers, others by the utilization of the auditory and the motor-speech centers, etc., every course in language should give opportunity for both forms of impressions and both forms of expression, *i. e.*, for hearing, and seeing (reading); for speaking and writing.\*

3. Language study is best cultivated by utilizing the nervous energy of all four centers, that is, the ear, the eye, the vocal organs and the hand. Each must support the other, thus heightening the total impression.

4. Generalizations, in this case principles and laws, must base upon sense perceptions, in this case spoken or written words and phrases, and must follow, not precede them. Ample opportunity is demanded to discriminate between various cases, genders, numbers, persons, tenses, modes, etc.; also between the various shades of meaning in words, and various modes of expression with slightly varying significance; also opportunity to make combinations as in reasoning from known roots to the various compounds of such roots, etc.; also opportunity for comparisons as in comparing the idioms of the foreign tongue with the mother tongue, as *e. g.*, in translating.

5. Retentivity depends upon the strength of the impression received in the class room. Aural impressions are heightened by visual, graphic and oral impressions. Since retentivity depends upon the frequency of the im-

\*It has been claimed that Americans are visualizers, and from this it has been argued that the reading method is the best for Americans. But it is a patent fact among psychologists that the combined action of the four speech centers is stronger than that of any one of them, and thus this argument falls flat. Moreover, the visualizer, above all others, needs to have his auditory and other centers developed.

pressions, language material must be worked over repeatedly in various ways, thereby insuring permanence of the impressions. The natural association of name and object must be made use of. That is, the learner shall not be taught to think from the foreign symbol to the symbol of the mother tongue, and from that to the object, but he shall be taught to think in the foreign language from the thing to the name and *vice versa*, just as he does in the mother tongue.

6. The ideal of persistence must be enforced by accomplishing set tasks, tasks sufficiently difficult, and including not merely memory work but reasoning as well, as, for instance, translation and "free composition," in which he compares and discriminates, chooses and rejects.

The imagination, the esthetic and the moral feelings must be fed by reading literature of high moral and esthetic standard, and by laying emphasis on the qualities which are to be inculcated.

CHARLES HART HANDSCHIN

#### ACADEMIC FREEDOM

TO THE EDITOR OF SCIENCE: In the current issue of SCIENCE is a letter on the subject of academic freedom, in which is given a quotation from an address delivered some years ago by President Schurman. Your correspondent regards the statements in the address as highly commendable, but it seems to me that the address contains within itself the "enzym" of its decomposition.

Academic freedom is like friendship "but a name that lures the soul to sleep." Freedom of teaching is permitted only so long as no serious attack is made on widely received opinions. As the "Professor" says, in Mallock's "New Paul and Virginia," "Opinions can only be tolerated when they lead to no possible consequences." Let us suppose, for instance, that when Professor Schurman's address was published, a subordinate instructor in the university had spoken as follows: "When President Schurman speaks of 'God's truth' he speaks of something about which he knows no more than a gibbering idiot in

the nearest asylum. God, if he exists, has apparently not declared himself to anybody. All such allusions are either mere catering to popular superstitions, or are on the same plane as the beliefs of the lowest savages." How long would this instructor retain his place in the university? I would be pleased to hear what your correspondent would advocate concerning a person who should so express himself. A hundred other examples can be selected. What would become of a subordinate instructor who should at a Washington's birthday address say that Washington was a traitor and should have been hanged by the British, if they had caught him.

HENRY LEFFMANN

WHEN the necessity of freedom for university teachers and investigators is emphasized, it is never assumed that this freedom carries with it a license to do or say anything and everything. University teachers do not claim that they constitute a class with special privileges. But as a body of men with serious and important work to do, they claim the freedom that is necessary to enable them to perform this work and to fulfill their obligations to society. Freedom in this field, as everywhere, is a reasonable freedom, involving law, responsibility and due regard for others. Academic freedom has its roots and its justification in the duty which the teacher owes to his students and to the community. It may well be that at times it is just as important to emphasize this duty and responsibility as to call attention to the necessity of freedom. But one side is the counterpart and complement of the other: where there is no freedom there can be no responsibility, and where there is no feeling of responsibility there can be no genuine freedom. If this is true, it would seem to follow that the limits of a reasonable freedom can not be fixed by any abstract definition. What are the reasonable limits in any particular case must be decided by the whole set of circumstances, as judged by reasonable men living in a reason-

able society. Of course this involves a circle; but there is no way of escaping it.

J. E. CREIGHTON

#### SCIENTIFIC BOOKS

##### *An Introduction to the Study of the Protozoa.*

With Special Reference to the Parasitic Forms. By E. A. MINCHIN, Ph.D., F.R.S., Professor of Protozoology in the University of London. London, Edward Arnold; New York, Longmans, Green & Co. Pp. x+517. Price \$6.00 net.

When an "Introduction" to the study of a special group covers over 500 pages of which perhaps a third are in fine print, a reader might infer that the main text would require a lifetime to prepare and digest. Of the many students of the group described in this book not a few have given an entire lifetime and others are now devoting all of their energies to the main text. Amongst these Professor Minchin is one of the most conspicuous and best informed. We think, however, that he is a trifle too modest in calling this splendid presentation of a difficult field an "Introduction," for the great variety of subjects discussed, the judicial attitude assumed, and the wealth of references used, are more characteristic of a treatise than of a primer.

Like the majority of general works on Protozoa, this one consists of two main sections, one devoted to general problems, the other to special groups. Such treatment involves more or less repetition and requires many cross references, but is most useful in picturing the nature and extent of problems in general biology, as illustrated by the Protozoa. In the general section four chapters are devoted to the distinctive characters, modes of life, general physiology and reproduction; five chapters to the general organization and life cycles, and one chapter to fertilization and sexual phenomena of the Protozoa. In the more special part, one chapter is given to the Sarcodina, two to the Mastigophora, three to the Sporozoa and one to the Infusoria, while a concluding chapter deals with the general phylogeny of the Protozoa and with two doubtful groups, the Spirochaetida and the

Chlamydozoa. The sub-title of the book disarms criticism of the disproportionate treatment of the four special groups, the Infusoria receiving the least attention, but such treatment may go a long way in overcoming the too-common generalization that ciliates are the Protozoa, and may help to a broader comprehension of the biological value of representatives of the other and larger groups of unicellular animals.

The problem of karyokinesis, especially the evolution from simple to complex mitotic structures, is well treated; a more critical discussion of the so-called chromosomes in Protozoa and the evolution of chromosomes would have been a welcome addition, since there is the greatest confusion at the present time over this apparently simple matter. The terms "chromatinic" and "achromatinic" are used in place of chromatic and achromatic, the change being adopted on the ground that the latter terms have a distinctly different meaning in optics. We agree that the change is desirable, but there is little probability that it will have a wide following, since these terms are firmly grounded in modern biology. Another new term—"chromidosome" for the smallest unit of chromatin inside or outside of the nucleus, is most useful so also is the word "endosome" for the German term "Binnenkörper."

Minchin makes a distinction between Protozoa of "cellular" grade and those of "bacterial" grade, but the effort seems to be somewhat obscure and does not help much in defining the Protozoa, having a perplexing rather than a simplifying effect. The bacterial nucleus is sometimes a single karyosome which might be compared with a typical nucleus; more often there is no morphological nucleus, but chromatin granules are scattered about the entire organism. It is presumably this type of bacterial structure that Minchin refers to in Protozoa of bacterial grade, and if so the Spirochaetes might well fall within such a group; but these are treated separately as a doubtful group. On the other hand, some well-defined Protozoa, such as *Dileptus gigas*, for example, have similar scattered chromatin

masses, but could scarcely be considered of bacterial grade. Certainly all undoubted Protozoa are of the cellular grade and are characterized by nuclei more or less different from typical nuclei of tissue cells.

The discussion on syngamy and sex, although slightly halting in argument, is admirably presented. Minchin apparently favors the rejuvenescence theory, but finds a logical difficulty in the phenomena of parthenogenesis and autogamy and has apparently overlooked some recent work on variations as an outcome of amphimixis, as well as works recording failures to rejuvenate after conjugation in cultures. This general problem, however, has been so recently re-opened that the literature may not have reached him in time to be incorporated.

In dealing with the flagellates, especially the blood-dwelling forms, Minchin is perfectly at home and speaks with a first-hand knowledge that carries conviction. The life histories of the Trypanosomes and other hæmoflagellates are given with a firm touch and many of the facts are from his own hitherto unpublished results.

In the section on general physiology the usual physiological activities are concisely, but well, treated. The matters of degeneration, regeneration, and the phenomena of decreasing vitality in Protozoa are somewhat disappointing in the mode of treatment; so also is the neglect, throughout the volume, of evidence derived from the study of various types of Protozoa by the bacteriological culture methods, which for certain groups of the Protozoa, notably the Amœbæ, promise to throw a flood of light on the vexed question of pathogenic species. It is most uncharitable, however, to cavil over these minute defects, if indeed they are defects, when the vast and rapidly growing literature on the Protozoa is so admirably welded together in a readable whole, and we shall have occasion many times repeated, to thank the author for his labor, his critical insight, and for the judicious care with which he has selected the material embodied in this volume.

GARY N. CALKINS

*Food in Health and Disease.* By NATHAN S. DAVIS, JR., A.M., M.D. P. Blakiston's Son & Co. 1912. Second edition. Pp. 449.

It is fair to assume from a statement in the preface that the author expects this work to be used in the instruction of physicians and nurses. It would seem desirable that any publication to be used in this way for instruction in the principles of nutrition should present the latest and most reliable knowledge. This volume fails to meet this requirement. Not only does it contain many statements which must be regarded as erroneous, but some of the most important advances in our knowledge of food chemistry and metabolism receive no consideration.

One looks in vain, for instance, for a discussion of the recent additions to our knowledge of the efficiency of individual proteins for constructive and maintenance purposes. Osborne and Mendel have shown that the alcohol-soluble protein of maize, when it is the only protein fed and is supplemented by the other classes of nutrients in efficient forms, does not serve to maintain life, much less build tissue. Marked differences are observed in the efficiency of other proteins. Without question, the influence of certain food substances upon the secretion of the digestive fluids should also receive extended attention in a study of dietetics. It would seem that whoever is to assume the direction of the diet of the well and the sick should have some inkling of this most important new knowledge.

It is easier to be charitable toward omissions of this kind, however, than towards inaccuracies and looseness of statement. It is fair to inquire what justification there is for the statement that carbon dioxide "aids digestion by promoting chemical changes and muscular activity." The statements that "tissue waste is most rapid under a protein diet," "that nitrogenous food in greater quantities than are strictly needed to maintain nitrogen equilibrium will cause a waste of tissues as well as repair," and "in other words, all changes are stimulated by proteins," are most surprising. It is true that the body tends to

adjust its protein catabolism to the protein supply and that a sudden increase of protein in food causes a quite immediate increase in protein cleavage. This does not mean, however, that an excess of protein causes tissue waste because this increase in protein catabolism, due to an increased protein supply, undoubtedly occurs at the expense of nitrogen compounds that are still in a circulatory or labile condition.

There can be no disputing the fact that "animal food requires a considerable quantity of oxygen for its utilization"! It is well established, to be sure, that the amount of heat liberated by the use in the body of a given volume of oxygen is somewhat less for proteins than for carbohydrates. In view of the facts that oxygen consumption is practically proportional to the amount of energy developed and that all the nutrients require for their oxidation in the body "a considerable quantity of oxygen," the above statement seems to be somewhat peculiar in form, to say the least.

We are not told on what experimental evidence it is asserted that proteins are required for the production of nervous energy, nor is the difference between nervous energy or any other energy explained.

To make the terms "fibrinogen" and "casein" synonymous as the principal protein in milk is hardly excusable. Fibrinogen is a term given to the mother substance of fibrin. It is possible that the author had in mind caseinogen, a name once proposed for the casein of milk before coagulation.

Starch, cereals and vegetables, when cooked imperfectly, are characterized as "indigestible" and we are told that a "vegetable protein is very imperfectly digested and absorbed." In the first instance, the term indigestible may be used in the popular sense, difficult of digestion, for the author, in several places, confuses the meaning of the terms digestion and digestibility, but to state that a vegetable protein is very imperfectly digested and absorbed is, as a general statement, in utter defiance of facts. The records of digestion experiments with human foods show that on the average between 80 and 90 per cent. of

the protein of cereals, vegetables and fruit is digested and absorbed. Vegetable proteins, according to this author, "are mostly globulins." The proteins of wheat flour, of which we consume more perhaps than any other vegetable forms, consist chiefly of glutenin and gliadin, neither of which is globulin. It does not appear to be true that globulins predominate in other cereals. Legumin is made to resemble casein "in many of its chemical reactions." We now know that the legumins are globulins and they appear to have little similarity to the principal protein of milk. The theory that by churning "the albuminous envelopes of the fat globules of the cream are broken and the fat particles are permitted to commingle and form a solid mass" was abandoned long ago. Those who are making a study of milk advance the theory that by adsorption the fat globules cause a concentration of albuminous matter around them, but the breaking of the envelope through the agitation of the cream is now not accepted. The statement that sodium chloride acts in the blood as a solvent of the globulins would seem to be somewhat precarious.

In discussing cow's milk, the author informs us that "after the first week, it is usually the richest and remains about the same for months, provided the animal's diet is uniform." The fact is, as shown by numerous analyses of the milk of cows through the entire period of lactation, the milk is the least rich a few weeks after parturition and increases in richness as the period of lactation progresses, especially when there is a decrease in the yield. It seems to be assumed that a change in diet changes the composition of the milk which, in the main, is contrary to the results of extended observations.

When the author enters the field of practical dietetics, he still seems to be subject to error. In dealing with the influence of the diet upon the mother's milk, he gives a set of rules which, in the light of recent observations, should be lightly regarded. For instance, we are told that to increase the total quantity of milk and to decrease the total solids, there should be an increase in the proportion of

liquids in the diet. Such investigations as have been made do not bear out this statement. Nuts are said to be of little value as food, but their composition and digestibility show them to be highly nutritious. Fish is classed as "an economical kind of protein food." This may be true of certain species, especially when salted or smoked, but some species when bought in the fresh condition, as for instance blue fish, furnish a very expensive diet, much more so than even the expensive meats.

Gravity cream is said to contain 16 per cent. of fat. If the term "gravity" is used in the usual sense as applied to cream raised by deep setting and pan setting, then under some conditions it would contain double that percentage of fat and even more. Cream does not have a uniform composition, but varies greatly according to conditions.

It is hardly necessary to multiply these references. There is running through the first part of the volume, which relates to the general principles of nutrition, a general tendency to inaccuracy and indefiniteness of statement. For the purposes of instruction, the language might wisely be condensed and reference to unimportant details omitted.

No discussion is attempted in this connection of the author's recommendations as to the diet for invalids and for persons in health under various conditions because he states that the recommendations "are largely based upon my own observation" and such observations constitute original data. No intelligent discussion is possible unless the extent and character of these data are understood.

W. H. JORDAN

NEW YORK AGRICULTURAL  
EXPERIMENT STATION

*Home University Library of Modern Knowledge.* Edited by HERBERT FISHER, GILBERT MURRAY, J. ARTHUR THOMSON and WILLIAM T. BREWSTER. New York, Henry Holt & Company.

*The Cambridge Manuals of Science and Literature.* Edited by P. GILES and A. C. SEWARD. New York, G. P. Putnam's Sons.

An anecdote which greatly impressed my boyish imagination some thirty-five years ago related to certain little scientific primers in terra-cotta colored cloth, written by such men as Huxley, Tyndall and Lubbock, and published, I think at a shilling, by Macmillan. The story was that some one had remonstrated with Macmillan for getting such eminent men to prepare these simple little works, when "any schoolmaster could have written them." The publisher replied that his experience had shown him that it took just such men to write good primers; that it was one of the most difficult things to accurately and effectively present the gist of any scientific subject, and attempts to have such work done cheaply by inferior men had always given more or less unsatisfactory results. Since that time multitudes of elementary scientific works have appeared, and the opinions attributed in the story to Macmillan have not been shared by all their publishers. We could hardly say, at the present time, that excellent works may not be written by men of small scientific reputation; but it assuredly remains true that they must be written by men of good training and ability. The abounding faults of our current text-books bear witness to the reprehensible lightness of heart and mind with which, in a commercial age, the teaching profession attempts to gain money and reputation.

The two series of volumes now before us, issued from New York, but prepared and originally published in England, represent new attempts to carry out the Macmillan plan. Essentially products of the universities, they are part of the general scheme of "university extension" which now finds so much favor. Varying greatly in literary and perhaps scientific merit, they maintain on the whole a high standard; and in nearly every case it may be said that the author is an eminent representative of the branch of science he discusses. The field covered is so large that no reviewer can critically consider more than a small minority of the volumes, yet in a sense he can judge best the ones on unfamiliar sub-

jects, testing by his own experience their power to interest and instruct. Tried in this way, I have found many of these little books quite inspiring, and have learned much from them.

The Home University Library volumes are larger and more pretentious, averaging about 250 pages, but selling at the very moderate price of 56 cents, post free. The Cambridge Manuals, with about 150 pages, sell for 40 cents net. The general appearance of the Home University volumes is very good, but I do not like the "rose-colored art cloth" of the Cambridge books, while the cover design, reproduced from a wood-cut of the year 1581, is ugly if historically interesting. The Cambridge Manuals usually deal with more specific or limited topics than the other books, and consequently are often more detailed or concrete. From the standpoint of a student this seems to be an advantage. The volumes are too numerous to be separately reviewed in detail, but a few notes on some of them may be useful.

#### *Home University Library*

*Matter and Energy.* By F. SODDY.

Very interesting and useful to one who is not a physicist. It is worth while to quote a few stimulating paragraphs:

Our most fundamental conceptions are, like ourselves, material. The elaboration of them is easy, but their simplification to suit the immaterial world, whither we now wish to embark, is difficult almost to impossibility. If our minds habitually thought in terms of electricity and magnetism instead of in terms of matter and motion, what a world would be opened up! (p. 165).

Modern science, however, and its synonym, modern civilization, create nothing, except knowledge. After a hand-to-mouth period of existence, it has come in for and has learned how to spend an inheritance it can never hope to restore. The utmost it can aspire to do is to become the Chancellor of Nature's Exchequer, and to control for its own ends the immense reserves of energy which are at present in keeping for great cosmical schemes (p. 247).

We may not be inclined to take all this quite literally; thus, civilization is not really

synonymous with science, even in its modern developments; but it is all very interesting and productive of thought.

*The Making of the Earth.* By J. W. GREGORY.

Parts of this seem rather uncritically written. We are astonished to read (p. 127) "the evidence, therefore, of the distribution of animals and plants proves the former existence of continents that have been dismembered and of land routes that have foundered beneath the oceans"; and there is actually a full-page map showing the distribution of the *Acræidæ*, a tropical family of butterflies, as part of the important evidence of land routes across the present oceans! On p. 244 it is stated that the first traces of vertebrates are Silurian, whereas it is generally considered that America yields Ordovician fish remains.

*Anthropology.* By R. R. MARETT.

Written in a breezy style, with due regard to the idea that "the 'dry bones' of history, its statistical averages, and so on, are all very well in their way; but they correspond to the superficial truth that history repeats itself, rather than to the deeper truth that history is an evolution. Anthropology, then, should not disdain what might be termed the method of the historical novel. To study the plot without studying the characters will never make sense of the drama of human life" (p. 242). On p. 40 it is implied that the antiquity of the Calaveras skull is still a matter of opinion. Here and there, the flow of rhetoric appears to lead to some looseness of statement, as when it is said that Wallace discovered the law of natural selection "at the same moment" as Darwin, instead of independently, as it should have been.

*Man. A History of the Human Body.* By ARTHUR KEITH.

Very interesting, with a good deal of information which will be new to the average biologist; some of it in fact based on new work by the author. We may perhaps object to the account (p. 171) of *Pithecanthropus* as "the fossil man of Java," without any expression of doubt regarding its humanity.

On p. 237 bacteria are called "fauna." Comparing the very different styles of the books on Anthropology and Man, I think it must be admitted that that of the latter is preferable.

A few others of special interest must be mentioned:

*Psychology.* By WILLIAM McDUGALL.

*The Principles of Physiology.* By JOHN GRAY MCKENDRICK.

*Electricity.* By GISEBERT KAPP.

### *The Cambridge Manuals*

*Links with the Past in the Plant World.* By A. C. SEWARD.

An admirable introduction to paleobotany, by one of the greatest authorities on that subject. As a frontispiece we have a picture of *Sequoia magnifica* in the Yellowstone National Park. A particular merit of this book is its treatment of living and extinct plants together, showing how they throw light on one another; it is especially to be commended to those botanists who think themselves excused from any consideration of fossils.

*Primitive Animals.* By GEOFFREY SMITH.

A most instructive treatment of the primitive members of various phyla. Used as a text-book, it might be made the basis of a very interesting introductory course in zoology. On p. 41, the account of the distribution of *Peripatus* is incomplete, and inaccurate in the statement that the animals do not occur in the northern hemisphere. It is also no longer permissible to speak of "a small number of closely related species," in view of such works as Bouvier's Monograph. The classification of animals at the end of the book is modernized, but the "Myriapoda" are left to include both centipedes and millipedes.

*The Individual in the Animal Kingdom.* By JULIAN S. HUXLEY.

An essay in zoological philosophy, or philosophical zoology, influenced, as stated in the preface, by Bergson. Well-known facts are brought forward to show how difficult it is to define an "individual," and it is finally concluded that individuality is a tendency which may be manifested in varying degrees. Con-

sequently the author makes the term cover cases in which he sees this tendency, although most of us, simply as a matter of nomenclature, will hesitate to follow him.

The communities of ants and bees are undoubted individuals. . . . When we come to man, this power possessed by one unit of entering into more than one individual "at once" becomes very marked. A man can very well be at one time a member of a family, a race, a club, a nation, a literary society, a church and an empire. . . . It yet remains true that the state or society at large is still a very low type of individual: the wastage and friction of its working are only too prominently before our eyes (pp. 142-143).

*Earthworms and their Allies.* By FRANK E. BEDDARD.

This deals principally with the geographical distribution of earthworms, but also contains a good account of their structure. The author is of course a well-known authority both on earthworms and distribution in general. I found the work very interesting, but I fear many will be repelled by the multitude of names of genera and species.

*Prehistoric Man.* By W. L. H. DUCKWORTH.

An up-to-date account of what is known about early man—yet of course not *quite* up to date, as it was printed before the recent discovery in Sussex. So far as I can judge, it seems to be admirably done, and one is really astonished at the mass of information gathered in recent years. All the really important contributions have been from the old world, and "it is important to notice that time after time the attempts made to demonstrate the early origin of Man in the American continent have resulted in failure, which in some instances has been regrettably ignominious" (p. 55).

Other interesting volumes are:

*Spiders.* By CECIL WARBURTON.

*Life in the Sea.* By JAMES JOHNSTONE.

*House Flies, and how they Spread Disease.* By C. G. HEWITT.

*The Migration of Birds.* By T. A. COWARD.

*The Work of Rain and Rivers.* By T. G. BONNEY.

*The Natural History of Clay.* By ALFRED B. SEARLE.

*The Origin of Earthquakes.* By CHARLES DAVISON.

*Rocks and their Origins.* By GRENVILLE A. J. COLE.

*The Modern Locomotive.* By C. EDGAR ALLEN.

Considering that high general level of excellence, together with the very moderate prices, it would seem that almost any public library or large high school would do well to obtain both series. The treatment, usually different from that of the conventional text-book, is likely to interest many readers, some in one subject, some in another. There is not as much duplication in the two series as some of the titles might suggest; thus "Anthropology" and "Man" in the one do not at all take the place of "Prehistoric Man" in the other.

T. D. A. COCKERELL

UNIVERSITY OF COLORADO

*On the Foundation and Technic of Arithmetic.*

By GEORGE BRUCE HALSTED. Chicago, The Open Court Publishing Company. 1912. Pp. 133.

The main purpose of this book is to place the number concept of modern mathematics within easy reach of the teacher in the grades. That there is reason for the existence of such a text is apparent from the fact that people in general and to some extent even teachers of arithmetic still look upon mathematics as "the science of quantity." The primitive number concept of modern mathematics has nothing to do with quantity. Mathematical research on this subject has been slow in commanding the attention of non-mathematicians. It is not very many years ago that a prominent American psychologist published a book in which the simple act of "counting" was declared to be an act of "measuring." It is not very long since, that a series of arithmetics was published in which the primitive idea of number was presented as being that of "ratio." Dr. Halsted brings out clearly and strongly the fact that primitive number, whether considered from the standpoint of its

modern logical exposition, or from its historic development, is wholly divorced from measurement, and that number viewed as a ratio presupposes counting and is a more involved concept. The book under review contains an able presentation of fundamental concepts. This every one familiar with Dr. Halsted's earlier works had reason to expect.

The leading topics discussed in the book are as follows: The genesis of number, counting, genesis of our number notation, addition, multiplication, subtraction, division, decimals, fractions, measurement, mensuration, order, ordered sets, ordinal number, the psychology of reading a number, arithmetic as a formal calculus, suggestions on the teaching of arithmetic.

Halsted makes the interesting observation that, besides the "ordinal number" and "cardinal number," modern civilization has introduced "nominal number" used as a proper noun, as in the telephone service. "Since the size of the number and its place in the number series are here alike irrelevant, the whole stress falls upon its recognition as a unique name."

The text contains numerous historical statements, some of which are open to criticism as not embodying the latest researches. Moreover, there is a frequent lack of bibliographical reference to authorities. Thus Halsted gives  $\pi = 3.14 +$  and  $\pi = 3.1416 -$  and then adds:

This is historically the first meaning of the signs  $+$  and  $-$ , which arose from the marks chalked on chests of goods in German warehouses, to denote excess or defect from some standard weight.

In view of the fact that historians have been in doubt as to the exact origin of  $+$  and  $-$ , the authority for Halsted's categorical statement would be interesting. Cantor<sup>1</sup> and Tropfke<sup>2</sup> both express themselves with great reserve on the validity of the explanation endorsed by Halsted. Eneström in a later re-

<sup>1</sup>Cantor, "Geschichte der Mathematik," Vol. II. (2), 1900, pp. 230, 231, 320.

<sup>2</sup>J. Tropfke, "Geschichte der Elementar-Mathematik," Vol. I, 1902, p. 134.

search arrives at more positive results, indicating a different origin for  $\div$ . He shows that in Widman's printed arithmetic of 1489,  $\div$  had not yet become a purely mathematical sign, that with Widman  $\div$  meant simply "und" (and), in conformity with a practise of the middle ages, according to which a symbol closely resembling  $\div$  was used for "et."<sup>3</sup> It is now known that Widman possessed a manuscript algebra in which  $\div$  is used for "et," even in cases where "et" does not mean addition.<sup>4</sup> Widman in 1849 sometimes indicated subtraction by the special symbol  $\div$ , a usage found somewhat earlier in a Dresden manuscript of the year 1481.

Halsted attributes decimal fractions to Stevin (1585), but makes no mention of the earlier use of decimals by Vieta<sup>5</sup> (1579) and Rudolff<sup>6</sup> (1530). Halsted mentions Napier (1617) as the first to use the decimal point, but the period (or the comma) was used by Bürgi as early as 1592,<sup>7</sup> by Prätorius in 1599<sup>8</sup> and by Kepler in 1616.

FLORIAN CAJORI

COLORADO COLLEGE,  
COLORADO SPRINGS

*Treatise on Light.* By CHRISTIAAN HUYGENS. Rendered into English by SILVANUS P. THOMPSON. London, Macmillan & Company. 1912. Pp. vii + 128.

Ever since its birth, in 1690, the wave theory of light has been adapting itself to environment. Just at the present moment, when the completeness and perhaps the competency of the wave theory is being called in question by certain phenomena of radiation and radioactivity,<sup>9</sup> an English translation of Huygens's

<sup>5</sup> *Bibliotheca mathematica*, 3 F., Bd. 11, 1911, p. 340.

<sup>6</sup> *Bibliotheca mathematica*, 3 F., Bd. 10, 1909-10, p. 243.

<sup>7</sup> *Teachers College Bulletin*, 1910-11, No. 5, p. 19.

<sup>8</sup> Cantor, *op. cit.*, Vol. II. (2), 1900, p. 619.

<sup>9</sup> W. H. Bragg, evening discourse before the

great "Treatise on Light" is particularly opportune. The fact that this translation has been made by Professor Silvanus P. Thompson is an ample guarantee that it has been done in a scholarly and sympathetic manner. Two distinct courses are open to one who wishes to transfer into English the thought of a foreign author who lived more than two hundred years ago—either he may employ the English phraseology of our own day, or he may use that which he conceives to have been the current diction of the period in which the work was composed. In either case he must avoid anachronisms, and in either case the problem is difficult. So many modes of expression are common to the languages of western civilization and so many of these forms have disappeared from our language during the last two hundred years, that a certain quaintness is inevitably given to any translation of old French, German, or Italian, in which particular pains is not taken to avoid these obsolete phrases. It is the second of these alternatives which Professor Thompson has chosen. The result is that the volume including its title page, table of contents, text, paper, binding, typography, size, and English style, is as nearly as possible what it would have been if Huygens had lived and worked and published on the other side of the English Channel. This is not to be understood as meaning that the translation is in any sense a literal one, for it is precisely the spirit of the work which Professor Thompson has caught and has faithfully reproduced. In brief the volume is in every way worthy of the great contributions to science which it contains. The first three chapters in which Huygens's principle is enunciated had already been made available to English readers through *Harper's Scientific Memoirs*. But the full evidence for Huygens's principle can only be obtained by understanding Chapters 4, 5 and 6. Atmospheric refraction is explained in Chapter 4 practically as we have it to-day. In Chapter 5 the wave sur-

British Association at Dundee, *Nature*, 90: 559 (1913); R. A. Millikan, vice-presidential address before the American Association for the Advancement of Science, *Science*, January, 1913.

face is worked out for Iceland spar. Here it is shown how a ray may fall obliquely upon a plane surface without suffering refraction. Here too is set forth the invention of the ellipsoidal wave surface to explain refraction in uniaxial crystals—one of the cleverest chapters in the entire history of science. The sixth chapter is given over to “the figures of transparent bodies which serve for refraction and for reflection.” Here the principle of “equivalent optical paths” is employed with its well-known elegance. The thanks of all students of optics are due to both translator and publisher for this complete and accurate rendition of a memoir which has long been so rare and expensive as to be practically out of reach of the ordinary reader.

#### SPECIAL ARTICLES

##### THE HISTORY OF LOST RIVER

In a previous paper written over a year ago and published by the Society for Protection of New Hampshire Forests, in their annual report for 1911, I tried to solve the problem which Lost River presents. Since that time I have made several visits to Kinsman Notch and have each time found new evidence on which to base conclusions. The following paper is offered as a further attempt at an explanation, based on the new evidence.

Lost River is a small stream rising in Kinsman Notch, about seven miles in a westerly direction from North Woodstock, New Hampshire.

The spectacle which presents itself on entering the river is very confusing. The river is immediately lost to view among a mass of huge granite blocks, some of them as large as average dwelling houses. Large potholes are numerous, as well as many beautifully curved water channels. Many of the potholes are fractured and fragments of these lie in the general mass. By careful inspection it is seen that this is an old rock gorge, and that something violent has taken place. Many joint blocks have fallen in, making it impossible to follow the water of the river in its course without ladders and bridges. The Society for

Protection of New Hampshire Forests, has purchased 148 acres, including the Lost River and the overhanging cliff, and has placed ladders and bridges in the gorge, so it is no longer difficult to see all the interesting points. There are two sets of caverns (so called because of large vacant spaces between the joint blocks), an upper and a lower. The upper caverns are about one quarter of a mile long. The stream emerges from these at Paradise Falls, flows unobstructed for about 150 feet, and plunges again beneath another mass of joint blocks, the lower caverns. The latter are not so imposing nor as extensive, although very interesting.

In contemplating this heap of granite blocks with the purpose of finding an explanation to the riddle, there are three agents which present themselves as seemingly capable of bringing about such confusion: frost action on a large scale; the disruptive force of a moving glacier; and earthquake action.

There has been considerable frost action in the gorge, and without doubt many blocks have been slowly wedged apart and fallen down from the sides of the gorge. That frost action, however, does not account for all the falling and movement, is to me quite evident. When in the lowest caverns one finds cases where blocks which have slipped from between other huge blocks in place, have left the upper and lower blocks entirely unmoved in the solid ledge. Smooth slickenside-like patches give evidence of a rapid and violent movement. This does not resemble frost action. The fearful confusion and pell-mell attitude of the mass also bespeak something more than the gradual work of frost.

The disruptive force of a moving glacier would seem at first glance capable of creating such a confused mass of joint blocks. It could not account, however, for the movements below the solid ledge, as described above. In one case I found a movement in a lateral direction between two blocks. The lower one is evidently in place and a part of the solid ledge, and the upper one has moved against the direction of movement of the ice about four inches. If ice were accountable for the slip,

surely the lower block could not have been moved, and the upper block would not have moved contrary to the ice motion. If the slipping can be explained by frost action, the positions of the other blocks can not, for they have evidently been thrown about by some other force. Furthermore if moving ice caused the confusion, one would naturally expect to find several different kinds of rock in the gorge. As far as I have explored the river one kind of rock only is present, a rather coarse biotite granite. A dark schist occurs in Beaver Meadows and some fragments of this should be found in Lost River only half a mile away. In the true moraines 100 yards away to the south, abundant fragments of this schist are found, but nothing of the kind in Lost River.

The fact that many of the potholes are cracked, disrupted and weathered as deeply as rocks outside of the gorge makes it evident that most of the potholes were formed before the main force which caused the confusion came. In any event most of the potholes were formed when the river had much more sediment than at present, and presumably this was during Glacial Period times, or at least when the ice had not retreated wholly from Kinsman Notch. The present amount of flow of very clear water is too small to account for the larger potholes. The largest of all is about twenty-five feet in diameter, narrowing toward the top. It has been badly broken and about one half only remains in position.

From the extraordinary positions of some of the water-worn channels it seems possible that much of the water work was done subglacially, although there is no proof as yet that such was the case. The main movement of the great ice sheet was south about 6° west, while Kinsman Notch at Lost River runs nearly east and west. It is probable that the ice in Lost River was nearly stationary during the height of glaciation, and that the main body passed over it with a shearing motion toward the south. The drainage under the ice would follow the present natural slope.

A study of the ground between Lost River and the cliff to the north helps to an under-

standing of what has probably taken place in the river. The way is difficult and somewhat dangerous. Huge blocks of granite are met with at once. They are piled in a pell-mell manner. As one ascends the blocks become somewhat smaller. There has undoubtedly been a large rock fall and one which immediately suggests a heavy earth shock as the starting force. Gradual weathering and falling would not account for the manner in which the rocks are wedged together. Weathering on all the large blocks of the rock fall, and on those in the river, has gone, as far as I can judge, to the same extent. From this fact it is also natural to conclude that the fall was of a sudden nature and not gradual. If the blocks had fallen one by one, weathering should have progressed to very different extents in different blocks. The granite of the cliff and that in Lost River is the same. There are no traces of any rock but the local granite in the rock fall, so this immediately does away with any ideas of a lateral moraine. It is very evident from the amount of weathering that this rock fall came long ago, and probably soon after the ice of the Glacial Period had retreated from Kinsman Notch.

It is now plain that most of the blocks in the river came from the sides of the original gorge, and not from the cliff, as I had formerly thought. Veins and dikes from the solid walls of the gorge can be found frequently in the loose blocks in the river, close to the places whence they were broken off. It is not always possible to say, on account of breakage, from which side of the gorge they came.

Although most of the blocks in the river came from the gorge itself, the rock fall from the cliff reaches to the very edge of the river, so it is almost certain that a number of the blocks came from the cliff. Surely the large number suggests more than just those which have fallen from the sides of the gorge.

That there was a strong earthquake in Kinsman Notch after the Glacial Period, and that this quake was the prime cause of the great rock fall, and of most of the confusion found at present in Lost River, appears likely. The movements of the joint blocks can not

be accounted for, as far as I have studied them, in any other way. The removal of a tremendous thickness of ice from the White Mountains would naturally require crustal readjustment of no small order, and hence a large earthquake or several of them would not be strange.

The evidences for an earthquake as the principal cause of the confusion in Lost River are: slickenside-like patches on a joint block over which another block had violently slipped; lateral movements among the blocks; the pell-mell manner in which the blocks are heaped; the great rock fall from the cliff, which probably came simultaneously with the shock in the river; the inadequacy of frost action to explain all of the confusion; and the elimination of the disruptive force of a moving glacier.

Although this evidence, positive and negative, does not prove that there was an earthquake in Kinsman Notch, it gives good ground for believing that there was such a shock. I have not overlooked the possibility of a local shock due to the rock fall itself. The effects observed appear too great for the vibrations a rock fall would be expected to produce.

I am greatly indebted to Dr. Philip W. Ayres, Forester of the Society for Protection of New Hampshire Forests, for guiding me to several important caverns which otherwise I must have overlooked.

HARVARD UNIVERSITY

#### AN ANALYSIS OF THE FACTORS CONCERNED IN THE HEREDITY OF COLOR IN TUMBLER

##### PIGEONS<sup>1</sup>

WHEREAS the usual methods for study of heredity serve only to show us the relation of one character to another, this work is an attempt to give our terms concerning heredity of color a real representation in the anatomy and physiology of the bird.

Some of the factors identified in these birds by breeding experiments follow: Red (*R*), Black (*B*), Intense (*I*), Spreading factor (*S*).

The *R* factor (in absence of *B*) is associ-

<sup>1</sup> Abstract of a paper read before the American Society of Zoologists, Cleveland, January 1, 1913.

ated with the formation of a melano-protein pigment, distinctly (pigeon) red in color, easily soluble in hot 4 per cent. sodium hydroxide. This pigment is found in reds and yellows. When *B* is present the chemical processes in the skin are profoundly changed, and a dead black exceedingly insoluble pigment is formed. *B* is completely dominant to *R*.

The effects of factor *I*, as seen macroscopically, are quantitative only. When *I* acts on red pigment there is 3.5 times more pigment formed, than when *I* is absent. Acting on black pigment *I* has a value of about 3. The physical form of the pigment is also influenced by *I*. In its absence red pigment exists as irregular masses, when it is present red pigment takes the form of small spherical granules about .4 micron in diameter, etc. On the other hand black pigment exists as spheres even in absence of *I*. When *I* is present black pigment sometimes may exist as rods.

The spreading factor *S* effects a uniform distribution of pigment throughout the barbule. When this factor is absent the pigment is aggregated in clumps, near the center of each barbule cell. This condition changes black to blue and dun to silver. The *S* factor also has an influence on granule form—and this influence varies with the presence or absence of *I*.

There is apparently a far greater mutual modification and interaction of factors in these birds than formulæ derived from external appearance alone indicate.

UNIVERSITY OF WISCONSIN

##### A NEW WALNUT

I THINK it desirable to place before the public the fact that I have been growing for eight or ten years a walnut hybrid originating from seed of *Juglans californica* which is a hybrid between that species and some tree, probably a *Quercus* of evergreen habit. As this new form comes true from seed and may be propagated indefinitely, it is worthy of a

specific name. I therefore take this opportunity of giving a few definite characterizations. A lengthy and detailed description will be issued later.

*Juglans quercifolia*, n. sp. The tree has a habit of growth of a *Quercus*, and in second generation forms it is more or less evergreen, that is the leaves fall late in the season and develop early in the spring. The leaves are trifoliate or unifoliate and the leaflets are circular and very distinct from those of the mother, *Juglans californica*. When there are three leaflets the terminal one is usually the larger. The tree bears nuts similar to those of the mother. The limbs have a small pith cavity which is closely septate. The catkins frequently appear on last year's wood in pairs and are closely approximate, the posterior is usually the shortest at a given date. The color of the new foliage is a darker green than is that of the mother.

NEWTON B. PIERCE

#### SOCIETIES AND ACADEMIES

##### THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

A SPECIAL meeting of the society was held in room 43 of the new building of the National Museum at 4:30 P.M., April 1, 1913, the president, Mr. Stetson, in the chair.

Dr. J. H. Gore, who has recently returned from a visit to the King of Siam, read a paper on "Siamese Life and Industries," profusely illustrated by lantern slides. The former included fine basketry, bronze vessels, silver vessels, matting, textile fabrics of silk and other material and hammered silver ware of admirable workmanship, the method of production being to fill a silver vessel with sand and hammer in the surface from the outside to form the ground, leaving the decorative human figures in series (beside other ornaments) in high relief. Usually the figures represent some mythological story. Dr. Gore's lantern-slide pictures of Siam included many farm-scenes, illustrations of games, festivities and elephant-capturing and views of the city of Bangkok, the aquatic human life of its rivers and canals, the palace, imperial crematories and temples, one of the latter being an exceedingly beautiful rock cavern temple of great renown.

Dr. Gore explained that the teak-wood forests

and rice culture are among the chief resources of the country, most of the ship-decks of the world being supplied from the former, now managed by an expert forester, while the export of rice is very great, about seventy rice mills of modern equipment being operated in Bangkok, beside, a large amount of similar work done by more primitive methods and appliances throughout the country. The soil is of the highest fertility and unequaled depth in the main valley of the kingdom. There are about eighty miles of good roads around Bangkok and the streets of the city are well made, modern street-car lines running on some of them: but the remainder of the country is practically without roads.

The late king was notable for divers modern and enlightened reforms, such as freeing slaves, relinquishing the royal ownership in the land in the favor of those who had been long in occupancy and use of it, waiving the exemption of the royal lands from taxation and compiling and publishing an edition of the Buddhist scriptures, which he supplied to the libraries of the world.

The inhabitants of Cambodia, he said, are nearly of the same stock of the Siamese, but regarded as inferior by the latter people, whose language is nearly akin to the Sanscrit. The human images before their temples are not idols, but for ornament. There is a flame-like upward aspiring tendency in their decorative work. No magical or religious importance is attached to white elephants, so called, which are albinoes, white only in patches; but these are regarded as rarities and curiosities and as such are given to the king.

# Important Books in Science

**The Mechanistic Conception of Life.** Biological Essays by JACQUES LOEB, Head of the Department of Experimental Biology, Rockefeller Institute for Medical Research. 238 pages, 12mo, cloth; postpaid, \$1.65.

In this his latest work Professor Loeb presents many of the current problems in biology, and discusses the question whether the phenomena of life can be explained by physical and chemical laws. He finds it possible to control by physical and chemical means not merely the processes of reproduction, but also the conduct of animals with reference to environment.

*Johns Hopkins Hospital Bulletin.* All eager to know more of the origin of life will find no modern book of its size nearly so instructive or inspiring.

**Heredity and Eugenics.** By JOHN M. COULTER, WILLIAM E. CASTLE, EDWARD M. EAST, WILLIAM L. TOWER, and CHARLES B. DAVENPORT. 312 pages, 8vo, cloth; postpaid, \$2.70.

Leading investigators have in this work made clear the present position of evolution, experimental results in heredity in connection with both plants and animals, the enormous value of the practical application of these laws in breeding, and human eugenics. The volume is profusely illustrated.

*British Medical Journal.* Those who are desirous of arriving at an estimate of the present state of knowledge in all that concerns the science of genetics, the nature of the experimental work now being done in its various departments, . . . and the prospects, immediate or remote, of important practical applications, cannot do better than study *Heredity and Eugenics*.

**American Permian Vertebrates.** By SAMUEL WENDELL WILLISTON, Professor of Paleontology in the University of Chicago. 152 pages, 39 plates, 8vo, cloth; postpaid, \$2.68.

This work comprises a series of monographic studies, with briefer notes and descriptions, of new or little-known amphibians and reptiles from the Permian deposits of Texas and New Mexico. The work is illustrated by the author.

*Athenaeum.* The paleontologist will welcome the work as a solid contribution to our knowledge of a fauna which is of exceptional interest to the student of evolution, inasmuch as it includes forms that help to bridge over some of the differences between reptiles and amphibians.

**Morphology of Gymnosperms.** By JOHN M. COULTER, Professor of Botany, and CHARLES J. CHAMBERLAIN, Associate Professor of Botany, in the University of Chicago. 470 pages, 462 illustrations, 8vo, cloth; postpaid, \$4.22.

Each of the seven great groups of gymnosperms is here presented in detail, and a final chapter discusses the problem of phylogeny and points out the evolutionary tendencies. The extinct groups are now included for the first time; and vascular anatomy is recognized as a morphological subject of first importance. The illustrations are numerous and in large part original.

*Nature.* The book is an invaluable record, admirably illustrated, of our present knowledge of the older type of seed-plants.

**Outlines of Geologic History with Especial Reference to North America.** Symposium organized by BAILEY WILLIS, of the United States Geological Survey; compilation edited by ROLLIN D. SALISBURY, Professor of Geographic Geology in the University of Chicago. 316 pages, 8vo, cloth; postpaid, \$1.66.

These essays and discussions embody the present state of knowledge and opinion concerning many of the fundamental problems of North American geology. The value of the book is greatly enhanced by the fifteen paleogeographic maps by Bailey Willis.

*Scottish Geographical Magazine.* The value of such a collection is very great, as each writer discusses only the formation or subject which has formed his own special study.

## STANDARD TEXTBOOKS

**Methods in Plant Histology.** With Illustrations. By CHARLES JOSEPH CHAMBERLAIN, Associate Professor of Botany in the University of Chicago. 272 pages, 8vo, cloth; postpaid, \$2.39.

**Animal Micrology.** By MICHAEL F. GUYER, Professor of Zoology in the University of Cincinnati. 250 pages, 8vo, cloth; postpaid, \$1.88.

**A Laboratory Guide in Bacteriology.** By PAUL G. HEINEMANN, Instructor in Bacteriology in the University of Chicago. 216 pages, 12mo, cloth; postpaid, \$1.59.

**Neurological Technique.** By IRVING HARDESTY, Professor of Anatomy in Tulane University. 196 pages, 8vo, cloth; postpaid, \$1.59.

**Laboratory Outlines for the Study of the Embryology of the Chick and the Pig.** By FRANK R. LILLIE, Professor of Embryology in the University of Chicago. 48 pages, paper; postpaid, 27 cents.

## THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

### THE SCOPE AND METHOD OF STATE NATURAL HISTORY SURVEYS<sup>1</sup>

It is a matter of common knowledge that before the middle of the last century many of the states of the union had established state surveys, and the national government was exploring the great west, fixing boundaries, locating routes and trails, and mapping the physical features in those vast areas. In both state and national surveys, geology received a large share of attention, but physiography, zoology and botany were not neglected. Many of the states, after making a recognizance of the geological features, identified and listed their plants and animals, as did the states of Maine, New Hampshire, Massachusetts, New Jersey, Ohio and Indiana. A condition to be noted in the establishment of a number of these early state surveys is that they were organized for the purpose of exploring and studying all of the natural resources of the commonwealth, scientific as well as economic. The survey of Michigan was established at the admission of the state to the union in 1837 as geological, zoological, botanical and topographic. The prevailing idea in these early surveys in the various states seems to have been what we may designate by the word *recognizance*, including geology, physiography, botany and zoology.

As the century continued through its third and entered its fourth quarter, the main attention of the state surveys became

MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

<sup>1</sup>Address of the vice-president and chairman of Section G, American Association for the Advancement of Science, Cleveland, December 31, 1912.

more and more centered in things concerned with mineral wealth; surveys that formerly had included natural history became restricted to geology, and the geology was often confined to economic studies, so that more than one geologist found himself subject to censure because he wasted his time on such supposedly worthless things as fossils. However, there was a great diversity among the states in the scope of the work they tried to do; and some of them published occasionally a volume on plants and animals. One of the best of such publications is the botany of California, appearing in 1880, the work on which was done by Brewer, Watson and Gray. This is a description of species with notes on habitat and range; but the most of the botany and zoology of this period is mere lists of species, as far as state surveys are concerned.

Special note should here be made of the survey of New York, which is the only example known to the writer that from the first has continued its natural history studies.

It is evident from what has been said that 30 years ago natural history had been largely eliminated from state surveys. In recent years, however, there seems to be a slight tendency to replace this work in the state survey. It is true that the number of states adding natural history to their work within the past quarter of a century has been small, only the states of Connecticut, Wisconsin, Michigan and North Dakota; but the surveys of New York, Illinois and Minnesota have shown renewed activity in natural history within this period, and the activity of agencies outside of official state surveys may be taken as an indication that other states will soon be persuaded to resume this work. These agencies include universities, colleges or museums that are doing some work without order from the

state, like the state museums of New Jersey and Louisiana; academies of science, like those in Indiana, Illinois and other states which have started surveys, some of these academies having their work published at state expense; volunteer associations, like the Botanical Seminar of Nebraska and the recent association of universities and colleges of Ohio; and, finally, individuals, like Pammel in Iowa, Hitchcock in Kansas, Nelson in Montana, Bray in Texas and Ramaley in Colorado, who contribute papers on the biogeography of their respective states, sometimes as bulletins of the institutions with which they are connected, sometimes as reports of academies, sometimes as a gratuitous paper in a geological survey.

Though we may feel encouragement over the awakening of interest in natural history, the present condition of the survey work in this subject in most of the states must be regarded as very unsatisfactory. Only 7 states are conducting continuous and systematic natural history surveys, and the most of the work done by outside agencies is more or less haphazard and sporadic. State academies seldom have funds enough to plan any large undertaking, and their future income is not sure enough to allow the laying of plans for a series of years. Men in colleges who may have started surveys give up their positions, and the work stops. Moreover, the scattering of the reports of surveys through several serials, official surveys, college bulletins, and academy reports, is not to be commended. Suppose one should wish to learn what had been published on the botanical survey of Ohio; in how many different publications would he have to search?

What is here said must not be interpreted as condemning state survey work outside of the official surveys. I am not

ignorant of the immense amount of valuable work that has been done by these volunteer agencies, work that would be still undone if it had waited for the call of the state. What a happy conjunction of ability, disposition and means was that in Nebraska which resulted in the "Phytogeography" of that state! A brilliant effect not repeated elsewhere. Also one recalls the valuable papers dealing with state vegetation in Vermont, New Jersey, Iowa, Kansas, Colorado and Texas, all done in recent years outside the official surveys. Success of this kind usually depends on the ability and activity of one or a few spirits whose mantles do not descend on their followers in office.

Besides their value to science, these efforts of individuals, academies, and other non-governmental organizations to contribute to state surveys have the valuable effect of stimulating and promoting interest in such matters till such time as the state will establish and conduct surveys at state expense. The establishment of the Biological Survey in Michigan in 1905 was the direct result of the efforts of the Michigan Academy of Science put forth for the preceding ten years.

There are probably few states in the union whose governing bodies have not been appealed to within the last quarter of a century for funds to undertake natural history surveys; and yet, in spite of all this effort, only four states within this period, to the best of the writer's knowledge, have responded with any considerable financial support—the states of Wisconsin, Connecticut, North Dakota and Michigan. The states of New York, Illinois and Minnesota began their natural history surveys before this quarter-century, and have continued them with fairly generous support.

Seeing that so many of the state govern-

ments have been appealed to for aid, and only seven are lending any considerable support, the conclusion is inevitable that the appeal has not strongly interested the governing body; or, to reduce the matter to terms of practical politics, the appeal has not aroused sufficient backing to move state executives and legislatures. What have been the terms of this ineffective appeal? Here let the writer call upon his own experience, while believing that his own experience has been that of many others.

The appeals for state aid have generally recited three classes of benefits to be enjoyed by the state from state natural history surveys. These three are classed as economic, scientific and educational. Taking a leaf from the uniformly successful experience of geological surveys, the natural history promoters have first of all argued for the economic good to the state to come from a natural history survey, in the way of better knowledge of agricultural lands, the promotion of forestry, the increase of fish and game, the discovery and combating of plant and animal diseases, etc. Although this argument has been strengthened by reference to the profitability of the fish and game industry of Maine, by depicting the sad state of the cut-over forest lands which the survey might remedy, and by numerous other citations, the legislators seem never to be sure that the argument applies to their own state; or, they are not sure that the benefits will not come without the cost of a survey.

The trouble with the argument for economic good seems to be that it is too vague to be convincing. The state geologist in asking for his appropriation proposes to explore a district for iron or copper, or to make a report on water-power or artesian waters. Local or corporate interests force

the matter through the legislature. The committee from the academy of science in presenting to the legislature its claims for a natural history survey, unlike the geologist, seldom has a definite promise of a definite task to be performed whose conclusion will be of economic interest to the state. It may be that some advocates have the ability to convince a legislative committee of the economic value to the state of a natural history survey; but it is certain that the most of the advocates of the past have not been so highly gifted.

The second argument usually employed in furtherance of a natural history survey pertains to the benefit to be enjoyed by science. The legislators have been reminded that the pride and patriotism of the state require that she should ~~dis~~her part toward building the great structure on which New York and Illinois are so faithfully laboring. On this argument the scientific advocate would like to dwell; but he realizes, at least he does after a little experience, that it is one of the least effective. The legislator counts on his fingers the scientists he knows in the state, and decides to risk their displeasure.

If it be conceded that, as a means of moving legislatures, the argument for economic benefit is weak because vague; and the argument for promoting science is ineffective because the class specially interested is small; what may be expected from the third argument most often used—the benefit to education, the benefit to the schools of the state?

In attempting to answer this question, it may be said that there are several conditions favorable to the use of this argument. The number of people in the state directly or indirectly interested in the work of the schools is very large. This large body is constituted by the better educated and more intelligent citizens, and

therefore one of the most effective classes of citizens. Again, the active members of this body are organized, extending from the state department of education to institutes, associations, clubs and circles, all of which could easily be reached if their influence was desired.

Some one now offers the suggestion that this proposal contains nothing not already tried, and that its use in the past has brought few results, seeing that but a paltry half-dozen states are at present conducting natural history surveys. I will readily admit that the argument has been unsuccessfully tried in several or many states within the past two decades. But I wish also to say that in my own state, Michigan, I believe it was the argument of educational benefit, more than any other, which resulted in the establishment of the biological survey in 1905. We appealed for aid in passing the bill to scores of teachers, and to several teachers' organizations. I wish also to say that the argument for educational benefit usually contains the same weakness that pertains to the argument for economic benefit: it is vague because it does not have definite tasks to propose, definite things that the survey will surely do for education. It is true that several of the reports or bulletins on biological matters, issued within the past twenty years by the state surveys of Minnesota, Wisconsin, Connecticut, Michigan and New York, are as much or more for educational as for scientific purposes. But, to my mind, the most of these are not convincing examples of the benefits which a survey can give to the schools. The most of them can not be used by the schools, either because they are not written so as to be used or they cover so large a territory that they arouse no local interest. These reports are not written wholly for science; for their descriptions and illustra-

tions are for many species little more than repetitions of what the scientist is familiar with elsewhere. Such publications therefore, are not very satisfactory illustrations of what a survey can do for the schools, either to the advocates of a bill before a legislature or to the school instructors whose aid may be sought for the bill. And if such productions seem unsuited to the purpose to those who are working for the bill, how shall these advocates employ these reports to show what the proposed survey may do? But can the argument for a state natural history survey be strengthened by holding up for its aim a definite, worthy and vote-compelling task, just as definite as the proposal of the geologist to explore an iron range?

The plan for a natural history survey which seems to me most likely to bring legislative consideration in the largest number of states, a survey which, if once started, will carry with it all that is desired for education, economics and science, is that of a *regional survey*, biogeographic in its nature, the reports of which should be so written as to be intelligible and useful to scientists, citizens and school children alike.

The method of regional surveys within a state is not new. New York uses it for the geological survey, making the unit-regions the quadrangles of the U. S. Topographic survey; and Maryland uses it, making the county the unit-region. The biogeographic method is now made to include not only flora and fauna with their distribution but also climate, topography, soil and general relation to environment. This biogeographic method of survey was used among the first by Professor Flahault, of Montpellier University, in France, and was later applied by R. Smith to survey the region about Edinburgh, and still later by Messrs. G. Smith, Moss and Rankin for

Yorkshire, England. In our own country similar attempts have been made by the Botanical Seminar in Nebraska, by Hitchcock in Kansas, by Livingston in two counties in Michigan, and by the Geological and Biological Survey of Michigan in the bulletin of 1911, entitled "A Biological Survey of the Sand Dune Region of the South Shore of Saginaw Bay, Michigan." This list names but a few of the attempts at biogeographic survey work, some of which have been noted successes, while others have had inadequate publication facilities. The method has been tried and found feasible. It was used by Schimper in his "Pflanzengeographie," in Spalding's "Distribution and Movements of Desert Plants," and is now in use in the making of that excellent series under the editorship of Engler and Pruden, "Die Vegetation der Erde."

A regional, biogeographic survey requires maps on which to spread data of distribution and habitat. Fortunately for the purpose, good base maps are already provided in the topographic survey of the government. Every state in the union has had a considerable portion of its area thus mapped in quadrangles of 20 to 50 or more miles square, and these maps are covered with contour lines giving just what is needed for the spreading of biogeographic data.

Conceive that a survey party goes into one of these quadrangles provided with a topographic map, that the work of the survey eventuates in a report on the phytogeography and the zoogeography of the region, that distribution data are spread on the topographic maps, that climate, soil and other physical features are given, and finally that all parts are so presented that the reading of the report and the study of the region will put the intelligent reader into possession of what that quadrangle

contains in the way of natural features and the influence of these features upon one another, and we have, it seems to me, the best kind of a natural history survey to which the state could devote its efforts.

One good report of this kind, made for a judiciously chosen quadrangle, or fractional quadrangle, would put a powerful weapon into the hands of those who are fighting for the establishment or the continuance of natural history surveys. If the report was successfully written so that it could be used by the school teachers and the schools, the advocates of a survey bill before the legislature would have a proposition just as definite in its promise as any geologist could offer for his work. If state academies of science, or other bodies who are working for the establishment of surveys, could, by their own efforts, produce one such report as a sample, it seems to me they would be able to present the strongest possible argument for the state to continue the good work, and they would find plenty of support on the part of the schoolmen and schoolwomen. Let me cite an illustration from my own state: Michigan is among the most backward in appropriating money for cooperation with the federal government in the making of the topographic survey. While some states have nearly all of their area mapped, and many states have more than a half mapped, Michigan has only fifteen to twenty quadrangles mapped. New maps have been added slowly and those interested in the survey have had to fight for every appropriation. But the people of the unmapped areas have at last discovered what these maps mean, and from various parts of the state calls for maps will be sent to the legislature just convening. So certain are the members and friends of the Geological Survey that the request for funds for topographic work will for the future take care of itself,

that for the first time they will make no effort in its behalf.

So, it would seem, may it be with the natural history survey. We have tried to use the argument of financial benefit, and it has not worked. We have tried the argument of the benefit to science, and it has not worked. The trouble with the first argument seems to be that we have not and we can not clearly define the work we would do so as to be reasonably sure of pecuniary returns. The weakness of the second argument is that relatively so few citizens would be benefited. The argument for educational benefit has met with little better success than the others, but this is probably owing to lack of definite plan. There is herewith proposed a definite plan which is believed would find supporters numerous enough to be influential. This method of doing the work, even in state surveys, has been practised by Adams, Ruthven and others in this country. I am urging the adaptation of the plan for the benefit of the schools of the state, believing that it can be made the strongest possible argument for the state survey.

Suppose such a biogeographic regional survey to be in operation, and suppose the reports to be so written up and the maps to be so made that the schools could use the reports for guides in the study of the geology, geography and natural history of the region, such a treatment of the survey would also furnish guides for all that increasing number of citizens who like to study nature. The benefits to these classes of our population, the young people in the schools, and the citizens who like the outdoors, would justify the survey. But there are other benefits that would follow: The survey could be planned so as to furnish data for instruction in agriculture and forestry and other applied sciences.

This biogeographic regional survey

would have all the scientific value attaching to the taxonomy, geography and ecology of such work. But besides this, such a survey would be the very best means of discovering the special problems that should always form a part of a state survey. There has been no intention in what has been said here to limit the work of the natural history survey to the surveyed quadrangles of the Topographic Survey. Rather, it seems to me, should this be adopted as the general policy of the survey; and, if successfully done, it could be made to carry the other scientific work of the survey. Important problems in morphology and physiology would arise, and sometimes the survey would wish to explore a region sparsely inhabited, the report of the work in which would not be of immediate use to the district, but might be of great value to science.

There are still two benefits to be mentioned which I believe would follow the adoption of the biogeographic regional survey. The first is the stimulation to investigation within the state in natural science, including natural history. This stimulation would produce better work as the result of opening up multitudes of problems on distribution, habits, etc. An increase of activity in the study of scientific problems of the state would tend to produce more valuable contents both for the survey reports and for the reports of the academies of science. We might even hope to see the lists of algae from Bermuda and the crayfish from Yucatan crowded out of these reports by the press of work done in the state.

The second benefit to follow, incident to the awakening of scientific interest in the state by the phytogeographic and the zoogeographic survey, and the problems discovered by these surveys, would be the

strengthening of the state academies of science, and the better understanding and sympathy among scientific workers, and between scientific workers and teachers of science. Many of us know how hard it is to make the state academy of science a worthy and profitable institution; we know how hard it is to obtain interesting matter for the annual programs. On the other hand, we know how many teachers out in the state would gladly participate in work on some problem. Cooperation between the state survey and the academy of science offers a means for many people of some scientific ability, but not specialists, to engage in profitable work. Some of this work can be used by the survey and some by the academy of science. The survey and the academy of science should be closely allied, and generously critical of one another.

As to the organization for a state natural history survey, I have nothing to give except a word of advice to those who have to start the work with but a small appropriation. Undoubtedly it would be best to have a specialist at the head of each scientific department represented; but if the annual fund is but a thousand or two, this is out of the question. But if the fund is only a thousand dollars annually, it is better to spend half of it in the employment of a director for part time, than to attempt to direct the work by a committee. The survey needs continuity of thought and purpose and a good deal of drudgery such as a committee is not likely to perform. If the reports or bulletins are designed for educational purposes as well as scientific, see that the written matter is presented so as to be capable of the use for which it is intended; much good matter has been buried by a bad presentation. It is not of the first importance that at the very start of the new survey the time-honored desig-

nation of "Geological Survey" should be changed to "Geological and Natural History Survey." Some legislators are fearful of the change. The important thing is to get an appropriation and start work. If a good start is made and the survey shows its desert, the change in title can come later.

In summarizing, I will but mention the few points I have tried to emphasize in this paper:

1. With but seven states in the union supporting natural history surveys, the present condition of such work the country over is unsatisfactory.

2. Though efforts have been made to induce numerous states to establish natural history surveys, such efforts have been attended with but little success.

3. The probable cause of failure lies in the difficulty experienced by the promoters of such surveys in stating definite and important results that the survey will accomplish.

4. The suggestion is made that if the plea for a natural history survey propose a biogeographic regional survey whose reports can be used as guides for study by the schools, the proposal will be definite and the object such as to interest a large body of supporters.

5. To make these reports serve the purpose of scientific treatises as well as guides to the study of natural history and biogeography, special care must be used in the organization and presentation of the material in written form.

6. The successful preparation of local guides for the study of natural history, phytogeography and zoogeography will enable the survey to carry on other scientific work.

F. C. NEWCOMBE

ANN ARBOR, MICH.

#### RECENT LEGISLATION AFFECTING EDUCATIONAL INSTITUTIONS IN KANSAS

THE state of Kansas, through its legislature which has just closed its biennial session, has finally decided to enter upon what may appeal to many as a doubtful experiment in educational administration, although it is hoped that a step forward has been taken. Essentially, the new arrangement consists in the application of the commission form of government, somewhat modified, to all of the state supported educational institutions.

Two years ago a bill to place the state university, agricultural college and normal school under one board of administration was passed. It will be recalled that Governor Stubbs at that time obtained the opinion of many prominent educators and administrators as to the probable success of the plan. Finding that there was almost a unanimous sentiment against this method of university administration, the governor finally vetoed the measure.

The present state officials were elected on a platform which pledged them to a reform measure which would place all higher educational institutions of the state under a single board. The motive for this change is a desire to secure a more efficient, and at the same time less expensive, administration, in that costly duplication of work in three separate institutions might be avoided without decreasing the efficiency or impairing the present high standards of all the institutions. In addition, it is believed that such a plan should lead, if properly carried out, to a better cooperation of all the parts of a complex educational system.

The act to bring about the centralization of authority in the management of the large state institutions was passed by the legislature, and signed by the governor on February 11. This measure includes the following institutions which are all placed under a single board of three members: The State University of Kansas, with the school of mines at Weir City; The Agricultural College at Manhattan, with its experiment stations located at Hays City, Dodge City, Garden City and Colby; the Normal School at Emporia, with the Manual Training Normal at Pittsburg and the Nor-

mal School at Hays City; the Kansas School for Deaf at Olathe, and the Kansas School for the Blind at Kansas City. Even this list may not be complete, as the branch schools have been scattered generously over the state. The members of the board are to receive a salary of \$3,500 each per year for their services.

An attempt to prevent political prejudices is found in the provisions which require that at least two political parties be represented, and that not more than one alumnus from any given institution may sit at the same time, on the board. Furthermore, the members must all be chosen from different congressional districts. Tenure of office as a member of the board is for four years, the appointments being made in such a way that the board can not be completely changed at any one time, except in case of disqualification and suspension by the governor.

The board is given a large hand in the management of the affairs of the institutions, being given power to elect the presidents and treasurers, to appoint all professors, instructors, officers and employees; to fix the salaries which shall be paid, and to make all rules and regulations for rank and promotion of the faculty and employees. Apparently the whole administrative policy of the institutions is placed in their hands, the presidents being merely their executors and advisers. The management of all the property, execution of all trusts, the direction of the expenditure of all appropriations, and the investment of funds received by legacy and otherwise, are also vested in this single board.

The board, which will have its central office at Topeka, will assume charge on July 1, 1913. The commission is required to visit each institution at least monthly, and to make reports from time to time of the needs of the institutions which they control for the state.

The members of the commission appointed by Governor Hodges are Ex-governor E. W. Hoch, well known as editor and lecturer; Mrs. Cora G. Lewis, who has been prominent as an organizer of school employment bureaus, and who is well known for her literary attainments; and Edward T. Hackney, of Winfield,

a graduate of the University of Kansas of 1895, and a prominent lawyer. The governor seems to have succeeded admirably in a difficult task. There is general agreement that the board is well fitted for the labors devolving upon it, and the friends of all the institutions are looking forward to a larger development under the new leadership. If an optimistic outlook makes for success in these matters, then the Kansas experiment should justify the high hopes entertained for the future.

Kansas has been exceedingly unfortunate in separating all of its educational institutions, and in pursuing the policy of scattering branch schools over the state for political reasons. It is impossible for the student who desires the advantages of the several schools to enjoy the privileges of all of them at once, as in the majority of states where at least agricultural college and university cooperate in education without duplication of forces and instructional staffs. In Kansas such a form of cooperation has been rendered impossible from the outset by the establishment of the institutions many miles apart. Wise foresight would have made the present conditions impossible. In no case have the agricultural colleges or state universities succeeded so well separately as when situated so that active cooperation and conjunction of forces are possible; and it remains to be seen whether the creation of a State Board of Administration of Educational Institutions can remedy a fundamental and irretrievable mistake in educational policy.

Those who have thus far guided the institutions will cooperate with the new board most heartily, and with singleness of purpose will seek to make the departure in administration successful from its inception. If carried out in the right spirit, this attempt at correlating and unifying the educational work of the state may result in very great advantage to all the interests concerned. The results of a somewhat different plan in Iowa have been far from satisfactory to any of the institutions. Of course, it is hoped and believed

by the optimistic people of Kansas that similar results will not be obtained here.

The *logical* outcome of this new movement in Kansas would perhaps be a gradual merging of the interests of all the state schools, and the realization of a greater University of Kansas. The *actual* outcome will be watched with more than usual interest by every one who has at heart the problems of efficient and liberal university administration.

CHARLES A. SHULL

THE UNIVERSITY OF KANSAS

#### SCIENTIFIC NOTES AND NEWS

DR. HUGH M. SMITH, deputy commissioner of fisheries, has been appointed United States fish commissioner.

THE Chicago Section of the American Chemical Society has elected Dr. Leo H. Baekeland, of Yonkers, N. Y., to be the recipient of the Willard Gibbs medal, founded by William A. Converse. The first award was made in 1911 to Professor Svante Arrhenius, director of the Nobel Institute, at Stockholm, Sweden. The second medalist was Professor Theodore W. Richards, of Harvard University. The formal presentation of the Willard Gibbs medal will be made to Dr. Baekeland at the May meeting of the Chicago Section of the American Chemical Society. The jury of award which selected Dr. Baekeland comprised Professor Alexander Smith, Dr. W. R. Whitney, Dr. E. C. Franklin, Professor W. A. Noyes, Dr. J. D. Pen-  
nock, Professor G. B. Frankforter, Professor John H. Long, Professor Julius Stieglitz, Mr. William Brady, Mr. E. B. Bragg, Mr. S. T. Mather and Dr. G. Thurnauer.

THE American Philosophical Society at its stated meeting on April 19 elected the following members: Dr. George F. Atkinson, professor of botany and head of the botanical department of Cornell University; Dr. Charles Edwin Bennett, professor of the Latin language and literature in Cornell University; Dr. John Henry Comstock, professor of ento-

mology and invertebrate zoology in Cornell University and non-resident professor of entomology in Stanford University; Luther P. Eisenhart, professor of mathematics in Princeton University; George Washington Goethals, U.S.A., chief of engineers of the Panama Canal; William Crawford Gorgas, Assistant Surgeon General, U.S.A., member of the Isthmian Canal Commission; Dr. Ross Granville Harrison, professor of comparative anatomy, Yale University; George Augustus Hulett, professor of physical chemistry in Princeton University; Dr. Clarence Erwin McClung, professor of zoology, University of Pennsylvania; John Dyneley Prince, professor of Semitic languages in Columbia University and president of the House of Representatives of New Jersey; Dr. Samuel Rea, president of the Pennsylvania Railroad Company; Dr. Henry Norris Russell, professor of astronomy at Princeton University; Witmer Stone, curator of ornithology of the Philadelphia Academy of Natural Sciences. Three foreign members were elected as follows: Sir Arthur John Evans, keeper of the Ashmolean Museum, Oxford; Sir Joseph Larmor, Lucasian professor of mathematics at Cambridge; and Dr. Arthur Schuster, professor of physics at the University of Manchester.

THE Lobachevsky prize of the Academy of Sciences of Kasan has been awarded to Professor F. Schur, of the University of Strassburg, for his researches in the foundations of geometry.

THE University of Edinburgh will confer the degree of LL.D. on the Hon. James Wilson, lately secretary of agriculture of the United States.

DR. ALEXIS CARREL and Dr. Hideyo Noguchi, of the Rockefeller Institute, Dr. H. M. Biggs and Dr. William H. Park, of the New York Department of Health, and Dr. John W. Brannan, of Bellevue and allied hospitals, have been made knights of the Royal Order of Isabella the Catholic by King Alfonso of Spain.

DR. THOMAS N. CARVER, of Harvard University, has been appointed by Secretary

Houston to take charge of the proposed "Rural Organization Service," a new branch of the Department of Agriculture, designed to aid the farmer in economic, social and cooperative buying and selling.

PROFESSOR FICKER, for many years assistant at the Berlin Institute of Hygiene, has been given leave of absence, so that he may take charge for one year of the bacteriologic institute at São Paulo, at the request of the Brazilian government.

PROFESSOR HEDINGER, of Basel, has been appointed director of the Königsberg Institute of Pathologic Anatomy, succeeding Professor Henke, who has been called to Breslau.

DR. A. J. CHALMERS, of Ceylon, known for his work on the etiology of pellagra, has been appointed director of the Wellcome Research Laboratories at Khartoum in succession to Dr. Andrew Balfour, who has been appointed director in chief of the Wellcome Bureau of Scientific Research in London.

PROFESSOR THOMAS C. CHAMBERLIN, head of the department of geology in the University of Chicago, and Professor Forest R. Moulton, of the department of astronomy and astrophysics, are members of a special committee of the Illinois Academy of Science appointed to recommend a revision of the present Julian calendar.

PROFESSOR CHARLES E. VAN BARNEVELD, of the school of mines of the University of Minnesota, has been offered an appointment as chief of the department of mines and metallurgy for the Panama-Pacific Exposition to be held in 1915.

DR. G. M. WHIPPLE, assistant professor of educational psychology, has been appointed as the delegate of Cornell University to the Fourth International Congress on School Hygiene, to be held at Buffalo on August 25-30 next.

DR. JOSE M. RUA, professor of biology in the University of Buenos Ayres, is visiting the universities of the United States.

THE three selected candidates for the vacant professorship of astronomy in Gresham

College, London, are Mr. F. W. Henkel, Mr. A. R. Hinks, secretary of the Royal Astronomical Society, and Mr. E. W. Maunder, superintendent of the Solar Department at the Royal Observatory at Greenwich. They will each give a probationary lecture before the Gresham Committee.

DR. H. M. W. EDMONDS, of the Department of Terrestrial Magnetism of the Carnegie Institution, will head an expedition to Hudson Bay designed to secure magnetic data in the region between the Albany and Severn rivers. A special attempt will be made to locate, as accurately as possible, the focus of maximum total intensity in North America, supposed to be in the vicinity of Cat Lake, near latitude  $52^{\circ}.2$  N. and longitude  $92^{\circ}$  W. The expedition will leave Washington in May and is expected to return in October of this year.

GEORGE B. RIGG, instructor in botany in the University of Washington, and special agent of the U. S. Department of Agriculture in kelp investigation in 1911 and 1912, is in charge of an expedition to western Alaska for the purpose of investigating the kelps of that region as a source of potash fertilizer. It is expected that a good deal of the work will be in the vicinity of Kodiak Island and the Shumagin Islands. The power halibut schooner *Gjoa* has been chartered for the trip. This expedition is sent out by the Bureau of Soils and is a continuation of the work that Dr. Frank Cameron has been directing during the past two years. The other members of the party are: Professor Robert F. Griggs, of the Ohio State University, and Mr. Sanford M. Zeller, graduate assistant in botany in the University of Washington. Dr. T. C. Frye, professor of botany in the University of Washington, is in charge of a similar expedition to southern Alaska. With him are Dr. Robert B. Wylie, professor of botany in the University of Iowa, and Mr. Dean Waynick, a student at the University of Washington. The gas boat *Zarembo* has been chartered in Seattle for the trip. Both of these expeditions will leave Seattle on May 1.

THE Maryland University School of Medicine is offering a course of twenty lectures on tropical medicine under the supervision of Surgeon J. A. Nydegger, of the U. S. Public Health Service, with the assistance of Dr. C. W. Stiles, Dr. H. R. Carter, and other members of the Public Health Service.

"THE Business of Agriculture in the College Curriculum" was the subject of an address to the students of the college of agriculture of the University of Illinois, given by Dean Price, of the Ohio State University, on April 11.

DR. LESTER F. WARD, professor of sociology at Brown University, and formerly paleontologist of the U. S. Geological Survey, died in Washington on April 18, in his seventy-second year.

THE death is announced, on April 7, at sixty-nine years of age, of Mr. F. G. Smart, fellow of the Linnean and the Royal Geographical societies.

DR. GEORG BOEHM, honorary professor of geology at Freiburg, has died at the age of fifty-nine years.

DR. JOHN SEEMANN, director of the physiological laboratory of the Academy of Medicine at Cologne, has died at the age of forty-nine years.

PROFESSOR H. ALEXAN BEZJIAN, Ph.D. (Yale, '74), teacher of physical science in Central Turkey College, Aintab, Turkey-in-Asia, died suddenly of arterial sclerosis, on February 10, 1913, in his seventy-sixth year. He was one of the most distinguished scientific men that Turkey has yet produced. His early training was received at Bebek Seminary, Constantinople, under Dr. Cyrus Hamlin, though he was born and brought up in Aintab. Except for two years spent in America in preparation, and a later year spent in France and England, he taught almost continuously in Aintab, and the neighboring city Marash, for fifty-six years. For thirty-seven years he was the senior member of the faculty of Central Turkey College, and he was in active service at the time of his death, always abreast of the times, eager for the latest news

or to learn of the freshest discovery. He was the author of many newspaper articles, and of books on "Natural Religion" "Guide to the Study of the English Language" (in Armeno-Turkish and English and the first book of its kind in Turkey), and "Elements of Physics." This latter book was published simultaneously in Armenian and in Armeno-Turkish. The Armenian form is now in its second and revised edition.

A VACANCY at present exists in the position of chemist, qualified in physical chemistry, in the Bureau of Standards, Department of Commerce, at Washington, D. C. This position requires a high order of scientific training, equivalent to that required by the leading American universities for a professorship in physical chemistry. The government seeks a man with a thorough and broad scientific education and several years' experience, and he must possess qualifications of a very high order in the theories of physical chemistry and their applications. He must be qualified to act as adviser in all fields where a knowledge of physical chemistry is required, and be capable of initiating and carrying out researches in the field of the bureau's varied activities. Ability to take a broad view on chemical subjects is essential. The entrance salary for this position is \$3,500 a year. The government is endeavoring to find the best man available for this work. The method of selection will be similar to that of an educational institution or business organization whose trustees or governing officers desire to fill a professional or technical position. The qualifications and fitness of applicants will be passed upon by a board containing men of recognized eminence in chemistry. Candidates will not be assembled for examination, but will be rated with respect to their education and training, their technical and professional experience, and their achievements as shown by publications and results accomplished. Persons interested should write to the United States Civil Service Commission, Washington, D. C. Letters of inquiry must be received by the Commission prior to May

15, 1913. Efforts will be made to reach a decision on this appointment by June 1, 1913.

THE U. S. Civil Service Commission announces an examination for associate physicist, qualified in metallurgy, to fill a vacancy in the Bureau of Standards, Washington, D. C., at a salary of \$2,200 a year. There is also announced an examination for logging engineers to fill vacancies in this position in the Forest Service, Department of Agriculture, at salaries ranging from \$2,400 to \$3,000 a year. The duties of this position will be: (1) Planning the most effective logging development of large national forest areas; (2) determining methods and costs of logging and manufacturing national forest timber and the market value of the products; (3) appraising the value of stumpage for sale; (4) inspecting and supervising the administration of timber sales.

THE Fourth International Congress on School Hygiene will be held in Buffalo, August 25 to 30. The officers are Dr. Charles W. Eliot, president; Dr. William H. Welch and Dr. Henry P. Walcott, vice presidents; Dr. Thomas A. Storey, of the College of the City of New York, secretary general, and Dr. Francis E. Fronczak, the Buffalo member of the executive committee. Delegates will attend from all the leading nations, from every college and university of note in this country and from various other educational, scientific, medical and hygienic organizations.

THE following provisional program of the Australian meeting of the British Association in 1914 is published in *The Observatory*:

July 3—Leave London by direct steamer (later by overland route).

August 4—Arrive Freemantle (for Perth), Western Australia. An advance party leaving England a week earlier than the main party will join the main party here.

August 8-12—Adelaide. Lectures; receptions; excursions.

August 13-19—Melbourne. Presidential address (first part); sectional meetings, etc.

August 20-26—Sydney. Presidential address (second part); sectional meetings, etc.

August 28-31—Brisbane. Lectures; receptions; excursions.

The earliest date of arrival in England is October 3; the route is by train to Adelaide, thence by steamer (*viâ* Suez to a Mediterranean port). Returning by steamer *viâ* Thursday Island, Port Darwin, Java, Singapore and Colombo, members will reach England about October 10-18. A party visiting New Zealand for a week will probably arrive home about the end of October.

#### UNIVERSITY AND EDUCATIONAL NEWS

WILLIAM B. REED, JR., whose death occurred recently in Putnam County, N. Y., has left an estate estimated at \$350,000, of which \$250,000 is left to Princeton University, subject to the life interest of his wife.

By the will of Addison Brown, ex-judge of the United States District Court, who died on April 9, Harvard University receives, \$10,000; Amherst College, \$5,000; Bradford Academy, \$5,000, and 200 shares of United States Steel preferred are left to the New York Botanical Garden.

MR. JOHN HOWARD FORD has given \$1,000 to Rutgers College for the purchase of the entomological library of the late Professor John B. Smith.

ON May 8 and 9 the University of Illinois will dedicate three new engineering buildings. These are the transportation building, the locomotive testing laboratory and the mining laboratory. A series of addresses by eminent men in the transportation and mining fields will be features of the program.

THE mayor of Dresden has published a pamphlet in which the plan for the foundation of a university in that city is described. The university is to be combined with the already existing technical and veterinary colleges. It is proposed that the city appropriate \$2,500,000 (10,000,000 Marks) for this purpose, and the state a sum of \$75,000 for the erection of buildings and an annual appropriation to defray the expenses of the scientific departments.

THE educational bill providing for five scholarships in each assembly district of New York state has been signed by Governor Sulzer. Each holder of a scholarship will receive from the state \$100 a year for four years to be applied toward the payment of the annual tuition fee charged by the college selected, which must be within the state. Scholarships will be awarded on the basis of school standing, and when they are all filled there will be 3,000 students at one time receiving state aid.

THE Sheldon traveling fellowships of Harvard University have been awarded in the sciences as follows: Donald Clinton Barton, Cambridge, for research in geology in Europe and Egypt during the summer; Sidney Fay Blake, for research in botany in Europe; Elmer Keiser Bolton, for research in chemistry at Berlin; Richard Maurice Elliott, for research in psychology, particularly in the psychophysics of handwriting, at Berlin and in the various psychological laboratories of Germany; Harvey Cornelius Hayes, instructor in physics, for travel in the United States, between September and February, for the purpose of observing the manufacture of alloys; Sidney Isaac Kornhauser, for research in zoology at Würzburg and at the Naples Zoological Station; Edward Hale Perry, for travel in the mining districts of the United States during the summer of 1913; Joseph Slepian, for research in mathematics in Europe, and Paul Dudley White, for research in pharmacology at London and Strassburg.

THE governing body of the Royal School of Mines, which is an integral part of the Imperial College of Science and Technology, London, are about to appoint a new professor of metallurgy in the room of Professor W. A. Carlyle, who is resigning in order to resume his professional work.

PROFESSOR EDWARD L. NICHOLS, of the department of physics of Cornell University, has been appointed dean of the College of Arts and Sciences.

MARTIN JOHN PRUCHA, of Cornell University, has been appointed assistant professor of

dairy bacteriology in the College of Agriculture of the University of Illinois, and assistant chief in dairy bacteriology in the Agricultural Experiment Station. He will be associated with the new head of the dairy department, Dr. A. H. Harding.

#### DISCUSSION AND CORRESPONDENCE

##### CONVENTIONAL POSITION OF MONOCLINIC CRYSTALS

##### A QUESTION IN CRYSTALLOGRAPHIC USAGE

TO THE EDITOR OF SCIENCE: So much of individual preference, not to say caprice, has in the past attached itself to crystallographic nomenclature and convention that it seems desirable, before introducing further innovation, to get the opinion of as many interested persons as possible as to the ultimate usefulness of any proposed change. For this reason the writer is asking space in SCIENCE, which probably reaches more of our scientific men who come in contact with crystallography than any other single publication, in order to test an idea as to the most desirable setting of crystals belonging to the monoclinic system.

*It is suggested that the ortho-axis, which is customarily placed in horizontal position, be set vertically.*

The objection at once presents itself that a change from the older long-established setting would necessitate restatement of the crystallographic data concerning all monoclinic substances.

It is, moreover, possible that familiarity with the ordinary types of animals has so accustomed the mind to thinking of a single plane of symmetry in vertical position that advantage should be taken of this facility of thought in presenting to students the somewhat analogous configuration of monoclinic crystals. That this argument should not be given too much weight, however, is evidenced by the fact that beginners of their own accord not rarely place the plane of symmetry of monoclinic crystal models in horizontal position, even after they have recognized the absence of other symmetry planes.

In favor of the proposed change may be cited the following arguments:

1. The conventional usage, already prevail-

ing in the tetragonal, hexagonal and orthorhombic systems, might be made general, viz., that when only one axis of symmetry is present this is set as the *vertical* axis.

2. That diameter which alone is distinguished from all those adjacent to it by its unique character would receive the unique treatment of vertical location, as is now the case in the tetragonal and hexagonal systems.

3. The lateral axes would, with this setting, be distinguished as the macro- and brachy-axes, as in the orthorhombic and triclinic systems. Every teacher realizes what a store of mental energy this would set free for more profitable application than its present task of keeping in their proper places the prefixes clino-, ortho-, macro- and brachy-.

4. The familiar spherical projections which Groth has used to show the kinds of crystal symmetry, and which are now widely used, would then have the same relative position in the monoclinic as in the other systems.

5. The failure of positive forms to occur in the upper front right octant could be obviated by placing acute  $\beta$  at the right of the observer, thus removing another unnecessary stumbling-block from the path of the learner.

The undersigned would be very glad to see an expression of opinion by any interested readers as to the desirability of making this change in the conventional position of monoclinic crystals.

A. C. GILL

CORNELL UNIVERSITY,

March 26, 1913

### QUOTATIONS

#### UNIVERSITIES AND INTELLECT

THIRTY-SEVEN years ago next fall Johns Hopkins University was opened, upon an endowment estimated at less than \$3,500,000. Yesterday, it was stated that the budget adopted by the trustees of Columbia University for the expenses of the coming academic year amounted to \$3,450,000. The foundation of the University at Baltimore was widely acclaimed as an event of the highest importance and the most hopeful augury. Never before had the income of so large a fund been placed at the disposal of the trustees of any new

American institution of learning; and the Johns Hopkins trustees had, in the choice of its president, and in the announced plans of the institution, made it plain that their opportunity was to be so used as to give to the higher intellectual life of the country a great and long-needed stimulus. The hope was entertained that the new university would be the means of introducing in America what had so long been vainly desired by scholars and scientists—the true university, in the European sense of the term. And that hope was not disappointed. The foundation of Johns Hopkins University marked the beginning of a distinctly new era in the history of higher education in America. What had formerly been the rare pursuit of a devoted scholar here and there has become the regular occupation of thousands of students in scores of colleges and universities. In many a field of research our country now makes contributions which, in point of quantity and sometimes also in point of quality, stand well alongside those of the leading nations of Europe; whereas, before the new start made in 1876, it was only some unusually gifted or ardent mind that went beyond the mere acquisition of the results of foreign learning and investigation.

In compassing with what would now be regarded as small means so signal an achievement, one cardinal feature of the policy pursued by President Gilman and the Johns Hopkins trustees was essential. There was one thing to which every effort was directed, every energy bent—the securing of the highest possible quality in the professors. A small group of real intellectual leaders formed the nucleus of the faculty; and in adding to them younger men in the various departments the keenest interest was constantly maintained in the discovery of unusual talent or exceptional attainment. Those who were at the university in its early years testify unanimously to the extraordinary exhilaration and inspiration of the atmosphere thus created. The buildings were extremely modest, and in large part of a makeshift character, being old residences altered at slight expense; the warning given by Huxley, in his notable address at the open-

ing, against putting into bricks and mortar what ought to be invested in brains, was rather by way of accentuating a policy already pursued than of advising its adoption. The revenue from the endowment proved to be even less than had been expected; much, it was felt, had to be done in the way of ordinary collegiate instruction to meet the needs of time and place; and if, with the means available for the distinctive purposes of the university, so great an impetus was given at Baltimore to the university idea in America, this must be ascribed, above all else, to the clear recognition of the prerogative of intellectual superiority as the one touchstone of university distinction.

The Columbia budget of \$3,450,000 is typical of the present-day expenditures of our larger universities. That they accomplish great results, results of extensive and varied usefulness, no one would deny. They cover a field much larger than that which formerly comprised the activities of our institutions of learning. They do much to promote civic enlightenment, and assist concretely in the solution of many problems of government. But we doubt whether any one would so much as claim that the enormous enlargement of university expenditure has been attended with any such nourishment of high intellectual standards or ideals as might have been hoped. Indeed, many a man may be tempted to compare in this respect the big and rich universities of to-day with the struggling institutions of half a century ago to the decided disadvantage of the present. The roster of the faculty becomes ever longer and longer; but how many of the names are such as it will thrill the students to recall thirty or forty years hence? There is always danger, in such matters, of the illusion of fond memory; the shining names of teachers under whom students were proud in after years to recall that they had sat were never very numerous. Still, it ought to be possible, out of the thick volume of professors' names in the catalogue of any of our leading universities, to single out a goodly list of those whose eminence is unmistakable and impressive, whose influence counts

as a great intellectual or spiritual force, whose presence gives to the university significance and dignity, to the enjoyment of whose instruction or inspiration the student will look back in after years as a never-to-be-forgotten privilege. Some such there are; but, in comparison not merely with an ideal possibility, but with what is actually found in foreign universities, they are extremely few and far between.

In comparison with this question, all matters of mere "management" are trivial. And it is for this reason, more than any other, that we have always regarded the magnifying of questions of administration in our American universities as so deplorable. To get men of real power into the professorships—that is the great problem. The question of salaries is undoubtedly a great stumbling-block; though even here the magnifying of administration adds to the difficulty, for a due recognition of the paramount importance of the professor would naturally tend to the making of such salaries as are needed to render professorships fairly attractive in a material sense. But important as this material side is, even more important are the less tangible elements that fix the character of the professorial life. These can not be had, indeed, simply by taking thought; the slow growth of tradition, and the temper of the national life as a whole, are preponderating factors. But we may help the growth of the tradition; and we may modify the influence of the national temper on the subject, for better or worse. As far back as Tyndall's visit to this country, in the early seventies, the British scientist took occasion to exhort his American audiences to prevent such waste of scientific genius as he found going on here, as illustrated in the case of Joseph Henry, abandoning physical research for administrative duties. We must make the life of the scholar and scientist attractive not merely in point of salary, but in point of honor, of leisure, of sympathetic environment; and all other tasks of university presidents and university trustees are of small moment in comparison.—*New York Evening Post*.

## SCIENTIFIC BOOKS

*The Eurypterida of New York.* By Drs. JOHN M. CLARKE and RUDOLF RUEDEMANN. New York State Museum Memoir No. 14. Albany. 1912. 2 vols.

This handsome memoir, illustrated by 121 text-figures and accompanied by an atlas of beautifully engraved plates, marks a notable addition to the series of special monographs published by the New York State Educational Department, the importance of which from a purely scientific standpoint can not be overestimated. Granted that a knowledge of the wonderful world we live in and of the manifold variety of life inhabiting it is of value for its own sake, even though it yields no direct material returns, there can be no question that the publication of this series of memoirs has contributed largely toward the advancement and diffusion of knowledge, in which respect the empire state long ago took the lead and has set a worthy example for sister commonwealths to emulate.

The new monograph before us is of a character such as might be expected of two authors who are recognized as holding front rank among invertebrate paleontologists. Not merely is this one of the regular contributions of trained specialists, valuable though it is as a great storehouse of facts. It is something more besides. Those familiar with the group of organisms considered must acknowledge it to be a philosophic essay which bears the stamp of authority, since everywhere one finds that conclusions have been reached only after mature deliberation, upon rigorous analysis of the evidence (often complex and confusing), and in the light of all previous researches that have been conducted in this difficult field.

As is befitting a scholarly production, the memoir is embellished by a graceful literary style, in which lucidity and directness of expression are conspicuous elements. Hugh Miller at his best could not have employed a more appropriate and smoothly flowing phrase, though he may have unwittingly inspired it, for we find his name bestowed upon one of these peculiar-looking creatures which

in the parlance of Scotch quarrymen are called "seraphim."

This volume represents the fruition of long-cherished plans, and more than fifteen years of patient collecting, preparation and study of an immense quantity of material. In localities formerly productive of good specimens but now no longer worked, nothing was thought of tearing down and rebuilding many rods of stone wall and foundations of old barns, on the chance of securing a bit of fresh evidence, or of following up a single new clue. In point of diversity, the thousands of specimens which passed under scrutiny during the preparation of this memoir exceed all other collections in the world. Little wonder, therefore, that so exhaustive an investigation should have yielded important new results and thrown a flood of light upon the structure and relations of this extinct order of merostomes. In fact, the organization of eurypterids has probably been studied in greater detail than that of any other group of fossil animals, and our precise knowledge of them is comparable with that which we have of recent arachnids. The theme is a fascinating one, and touches closely on human interests when we consider the theory, recently revived in some quarters, of the arachnid origin of vertebrates.

The general thesis of the book is that eurypterids, the king crab and other merostomes are arachnids, and share a common origin with the scorpion and its allies. As for the scorpions, to which a special section is devoted in the appendix, it is worthy of note that they exceed all other animal forms of high elaboration in point of racial longevity, having had a continuous existence from the Silurian onward.

A very important chapter is that which is devoted to a comparison of the anatomical structure and larval stages of development as observed in eurypterids, *Limulus* and scorpions. The conclusions reached from this line of research are: (1) that "the limulids and eurypterids were probably separate in pre-Cambrian time"; (2) that "neither *Limulus* nor the scorpions are derivable from the

eurypterids, but that all three, while related, have early separated, and that eurypterids are still nearest in their general aspect to this common ancestor"; and (3), while we have no clue as to what this common ancestor was, it is clear that the earliest and most primitive known crustacea (trilobites) do not stand in that relation, and therefore the derivation of various types of these arachnids from arthropods more primitive than the crustaceans seems a necessary inference. It is recalled in this connection that Bernard derives the crustacea from a bent carnivorous annelid, and that Beecher regards this view as partly confirmed by his discoveries concerning the ventral anatomy of trilobites.

For the study of the ontogeny of eurypterids the authors had at their command an unrivaled series of larval stages of four genera, ranging in size from a length of 2 mm. or less up to the adult condition. A comparison of growth stages leads to the important conclusion that there is a "general parallelism in the ontogeny of the eurypterids and *Limulus*." Not less brilliant and far-reaching is the discovery that the Cambrian genus *Strabops* fulfills tolerably well our conception of a generalized prototype from which Silurian eurypterids have descended. The adult *Strabops* so closely resembles the young of later genera as to justify the statement that eurypterids actually pass through a "*Strabops* stage" during their nepionic development. Herein is found fresh evidence in favor of the so-called recapitulation theory, or biogenetic law, as important in its way as the recognition of the "*Prestwichia* stage" of *Limulus*, and the goniatic and ceratitic stages of ammonites.

Confirmatory evidence in favor of the homologies between eurypterids and king crabs is found in the fact that *Pterygotus* and *Limulus* show a remarkable identity in structure of the compound eyes. The view of their common relationships thus receives strong support from a new body of facts, for, as shown by Watake and others, the visual organs of *Limulus* form an extremely peculiar structural type. Among the various special anat-

omies that have been minutely investigated, those which have to do with the compound eyes and genital appendages are particularly commendable, and the results gained are of signal importance.

The special essay on morphology and anatomy, together with the discussion as to the mode of life of these creatures, are replete with new and interesting details. Owing to limitations of space, we can only refer to these in the most casual way, and it must suffice to note merely the captions of some of the subordinate themes discussed, as, for instance, the following: Geological distribution and biogenic relations; mode of life; taxonomic relations; synoptic table of North American eurypterids. These lead up to the principal chapter, consisting of 232 pages, which is devoted to a systematic account of the group and is in every way most excellent. After this follows an appendix of 40 pages, in which are set forth the results of investigations and discoveries made since the body of the work went to press. Besides the valuable note on Silurian scorpions, already referred to, there are considered here the relations of several problematical forms, *inter alia* the pre-Cambrian bodies called *Beltina*, the genus *Hastimima* of White, and the suborder *Limulava* of Walcott. Appendices as important as this are welcome in any work for the choice nuggets of new truth they contain.

The greater part of this memoir necessarily deals with the concrete facts of observation and their adjustment to the present state of our knowledge. Nevertheless, an undercurrent of ideas appears to run through various passages, sometimes only suggested or hinted at, or again included within broad generalizations. And the central thought that informs these ideas proves to be an insistence upon the *fundamental human interest of the theme*. For really, is not the general theme one which involves questions concerning our own remote ancestry? And who knows whether we may not discover landmarks which shall point for us the way taken by advancing creation in its slow march through the ages, the end whereof is man? A gradual progression leading up to

man, that mite, that mere atom, that ephemeral fragment of nature! How insignificant a goal; and yet, strange paradox, that mite and that atom is able to comprehend nature, and great enough to know his own littleness. Alone among earth's creatures this being has intelligence fine enough to perceive that his thought is everything, even though it be "but a flash in the midst of a long night"; and even though all life be "only a short episode between two eternities."

Reflections of this sort must certainly have inspired the minds of the authors when writing many pages of this memoir; and in the reviewer's judgment the work has suffered nothing in consequence. Not long ago one Anatole France wrote a natural history of penguins. It is a capital work, and has opened our eyes to new and alluring possibilities of ornithology. But in the preface the author lays down certain rules for the guidance of fellow naturalists if they would greatly extend human knowledge and leave imperishable monuments behind them. Now assuredly Drs. Clarke and Ruedemann have done these things, as this memorial witnesses, yet they have gone exactly contrary to rule. Whence we infer that the learned academician must have been mistaken, for surely no one will accuse him of ever being ironical.

C. R. EASTMAN

CARNEGIE MUSEUM,  
PITTSBURGH, PA.

*Palæolithic Man and Terramara Settlements in Europe.* By ROBERT MUNRO. New York, Macmillan Co. 1912. Pp. 507. Price \$5.50 net.

"This volume contains the Munro Lectures in Anthropology and Prehistoric Archeology for 1912, being the first course since the lectureship was founded," in the University of Edinburgh. It seems especially fitting that the eminent archeologist after whom these courses are named should himself be the first to fill that lectureship. A standard is given which is of the highest and which, we may hope, subsequent lecturers will strive to maintain.

Those who are not in the small circle of prehistoric archeologists are prone to look upon their work askance, if indeed they do not ignore it altogether. "Early Bronze is a good enough term for articles in a museum," they say, "but it does not suggest a spiritual being. We can not get on terms of spiritual intimacy with the Early Bronze people. For all their flint arrow-heads, or bronze instruments, we can not think of them as fellow men." These prevalent views can come only from a distorted perspective, a perspective in which only the dull unrelated side of these things is open to our vision—when we see them as objects rather than as evidences. It must be confessed that the specialist is often more than indirectly responsible for this prevalent attitude. To Dr. Munro we must feel grateful for a masterful treatise which, without neglecting the minutiae and details, subordinates them to their true place in a scheme of wider relations. His facts are evidences, his evidences appear in their proper place in the larger *Culturgeschichte*. We can not be too grateful that, to use his own phrases, "the gnawing tooth of time" has allowed us to rescue from the "dustbins of ages" these few pages of an early history which archeological finds furnish.

The volume is divided into two parts, the first treating of Anthropology: Paleolithic Man in Europe, with supplementary chapter on the Transition Period, the second with Prehistoric Archeology: Terremare, and their Relation to Lacustrine Pile-structure. The volume covers a ground which no other English one duplicates, that of Sollas being more closely related to the first part, and that of T. E. Peet to the second.

Of the first part we have only two criticisms: A map showing the locations of the various described sites would add greatly to the value of the exposition, and a chapter dealing with the methods of burial would have been a valuable addition. The excellent maps incorporated in the author's *Lake Dwellings of Europe*, have their counterpart in the second portion of the present work, which deals with the Po Valley, and there is a chap-

ter devoted to methods of burial—not, however, giving us such valuable information in this regard as we obtain from Peet.

The author is concerned in the main with description, there being no less than 74 full-page plates in addition to the 174 figures. These excellent illustrations greatly enhance the value of the volume. We may regret that the author has not brought the problems out more sharply. The more important of his solutions of the problematic are probably these:

*Pithecanthropus erectus* represents a type, not necessarily intermediate between man and the monkeys, but one in which the erect posture had been assumed though the head-form of *Homo sapiens* had not completely evolved—"the seeming difference being due to the different standpoints from which the phenomena are contemplated." A *hiatus* between the paleolithic and neolithic in England must be assumed, the so-called mesolithic forms being incomplete neoliths; it is probably to be accounted for on the assumption that paleolithic man was driven out by the cold and the glaciers, to take refuge with the cave-men of France with whom he could easily communicate over the land now covered by the English Channel. Likewise, paleolithic man of Jersey could so communicate. The dual cultures found in the eastern and western parts of the Po Valley, respectively, are explained on the supposition that "the terramaricoli in their migration southwards took possession of these native villages, and lived in their hut-habitations, finding them as comfortable as their own pile-structures. If there was an emigration of terramara folk from Emilia to south Italy, who ultimately became the actual founders of Rome, surely they must have left some traces of their journey behind them. If so, what are these traces? To me the answer is not far to seek: they are scattered along the Adriatic slopes in the numerous hut-villages and cave-dwellings, which are described as containing unquestioned remains of terramara civilization." To this the classical archeologist will retort: *If there was such an emigration.*

The chapter describing Structures Analogous to Terramare in Other European Countries is most welcome, for we do not have a substitute in English.

The volume will appeal both to specialists, who will find it valuable for references, illustrations and descriptive material, and to the lay reader who wishes to have in easy, comprehensive form the latest results in European prehistoric archeology.

W. D. WALLIS

UNIVERSITY OF PENNSYLVANIA

*The Cotton Plant in Egypt.* By W. LAWRENCE BALLS. Macmillan & Co. 1912. 202 pages, 1 plate and 71 text figures.

The purpose of this book, as announced in the preface, is to abstract "the results of a series of researches made upon cotton plants in Egypt, which investigations, though diverse, were connected by the desire to know all that could be learned about the plant itself." The subject matter covers a wider range than is usual in books concerning cultivated plants. Morphology, physiology and genetics are treated in turn and the bearing upon agricultural practise of each phase of the investigations is constantly emphasized.

An "historical" chapter deals with the perplexing problem of the origin of the Egyptian type of cotton. Professor Balls champions the view that the existing varieties are "more or less heterogeneous complexes of heterozygotes." They are, it would appear, descended from fortuitous crosses of a brown-linted tree cotton of the Peruvian type, long existent in Egypt, with other varieties, among them probably American Sea Island, which was introduced there during the first half of the last century.

Brief accounts are given of the process of fertilization, of the development of the embryo and of the cytology of the fiber. One of the most interesting portions of the work deals with the influence of physical factors, especially temperature, light and soil moisture, upon growth and development. The author distinguishes two periods in the ontogeny of the cotton plant, the first beginning with

germination and the second with the appearance of the first flower. He believes that development is controlled during the earlier period mainly by air conditions, especially temperature, and during the second period mainly by soil conditions, especially water content. He regards as the limiting factor for growth what he terms "thermotoxy"—the supposed accumulation of injurious products of metabolism caused by high temperatures and aggravated by a deficient water supply. Varietal differences in length of the growth period would indicate corresponding differences in resistance to "thermotoxy." Experiments are described which deal with the effect of a high water table in checking root development and in inducing shedding of the flower buds. This subject is at present much discussed in Egypt in connection with the recognized deterioration of the cotton crop.

In the field of genetics fluctuation, natural crossing and heredity are treated. Much space is devoted to the application of Mendelian and post-Mendelian principles to cotton hybrids. This discussion, interesting and suggestive though it be, will scarcely inspire the cotton breeder with confidence that his practical problems will be speedily solved by the Mendelists.

By way of criticism, attention may be called to a certain lack of balance in the space devoted to different phases of the subject. Thus the morphology of the vegetative organs, which is of great interest agriculturally as well as botanically, receives but scant notice. One reads with astonishment that there is "apparent identity of all the modern varieties of Egyptian cotton in external appearance—for, even when grown side by side, they are scarcely distinguishable." Several of the varieties, when grown in Arizona from imported seed, have proven readily distinguishable by the characters of the leaves, bracts and bolls. There is also a tendency to put forth rather sweeping generalizations. Such are the assumptions, regarding fluctuation, that in a pure strain it "is the result of slight irregularities in a normally uniform environment" (p. 89) and that "physiology

explains it" (p. 90). It is also not very clear to the uninitiated why transmitting power "is not a mysterious vital function" merely because it "can be reduced to formulae." Several of the text figures are left without satisfactory explanation, either in the legends or in the text, and the reader would be saved time and trouble if the pages were cited in referring to the figures.

Nevertheless this little volume can not fail to be helpful and suggestive to all investigators of the cotton plant and not its least valuable mission is to show some of the ways by which scientific investigation of a crop plant may be brought to bear in improving agricultural practise.

T. H. K.

*Naturwissenschaftliche Studien am Toten Meer und im Jordantal.* Von Professor Dr. MAX BLANKENHORN. Berlin. 478 pages with geographical map and table.

Students of the geology of Palestine probably owe more to Dr. Max Blanckenhorn than to any other one author. The present volume is an account of his last expedition undertaken in 1908 at the request of the Turkish government. The ex-sultan, Abdul Hamid II., apparently desired to discover mineral wealth in the valley of the Jordan River and Dead Sea, which is his private property. Dr. Blanckenhorn, however, wisely insisted that the expedition should be primarily scientific, and not economic. The results justify his position, for Palestine is very poor in mineral wealth. Pure science, however, did not satisfy the Turkish government which still, in spite of repeated promises, owes Dr. Blanckenhorn twenty-five hundred dollars for expenses incurred at their request.

Dr. Blanckenhorn's work divides itself into three closely related parts, economic, geologic and physiographic. In respect to the first two we accept his results without question, but as to the third there is some doubt. Inasmuch as the geological formations of Palestine are almost entirely cretaceous, little mineral wealth is to be expected. The salt deposits of Jebel Usdum at the south end of the Dead

Sea would have some value if they were not so inaccessible. The same is true to a greater extent of the phosphatic rocks of cretaceous age which the author describes near Nebi Musa, east of Jerusalem, and near Es-Salt, in Moab, east of the Jordan. These latter deposits are estimated to have a market value of nearly a million and a half dollars, and perhaps much more. Nevertheless, an English company, after spending \$20,000 in prospecting, abandoned its enterprise, because the deposits are so remote, and because the directors of the Mecca railway imposed such onerous conditions of carriage. The only other valuable mineral product is asphalt, with which the cretaceous strata are largely impregnated, but the quality is not high, and the arid climate, rough topography and distance from the railroad prevent its exploitation at present. In discussing all these formations—salt, phosphates and asphalt—the author's geological observations are of more value than purely economic considerations.

Throughout the volume Dr. Blackenbom devotes himself mainly to strict geology. Unfortunately he has adopted the style of a diary in which his birthday, his bath, Turkish officials and the weather are mixed up with a great mass of minute geological details. These details are arranged according to the chance order in which he happened to see them, and hence are difficult to follow and to interpret in general terms. They serve, however, as a running commentary upon two highly valuable contributions, namely, an admirable and reliable geological map, a large part of which is Dr. Blanckenhorn's own work, and a table which sums up the pliocene and pleistocene history of Palestine. The portions of this table based upon physiographic evidence are the part of the volume open to question. A summary of late geological history as interpreted by Dr. Blanckenhorn is as follows:

**Lower Pliocene, or late Miocene.** Low stand of Mediterranean Sea. First upheaval of the highlands of Palestine, accompanied by east-west, or N.W.-S.E. faulting which gave rise to such features as the separation of Upper and Lower Galilee, the basin of Asochis in southern Galilee,

and the fault-scarp and plain of Esdraelon between Galilee and Samaria.

**Upper Pliocene.** Broad encroachment of sea in Syrian Desert. Small lakes occupying parts of the present area of the Sea of Galilee. Basaltic lava flows of Banias and el-Markab. Completion of first great erosion-phase of rivers.

**Gunz Glacial Epoch.** Level of Mediterranean Sea 330 meters higher than now. At the beginning of this epoch the depression occupied by the Jordan Valley, Dead Sea, Gulf of Akaba and Red Sea began to take form, while at the end occurred the great movements which gave final form to the deeply depressed graben in which lie these various bodies of water. With this went considerable faulting in a N.E., S.W. as well as N. and S. direction. Conglomerates and marls were deposited in the much-expanded predecessor of the Dead Sea.

**Gunz-Mindel Interglacial Epoch.** This was a short dry period during which the Dead Sea contracted so far that the thick salt beds of Jebel-Usdum were deposited.

**Mindel Glacial Epoch.** Sea 33 to 80 meters higher than now. Culmination of glacial period with small glacier in Lebanon. Highest stand of Dead Sea, which extended from the Sea of Galilee to Wadi Araba. The strand formed at this time is supposed by Blanckenhorn to be represented by what he calls the Haupt Terrasse or Terrace of Jericho. In the Jordan Valley he assigns to this a height of 100 to 200 meters above the present level of the Dead Sea, at the north end of the Dead Sea a height of 50 meters, and at the south end a height of 486 meters. His natural inference is that there has been an unequal upheaval at the north and south, and a sinking in the middle. It seems impossible to accept this view, since, as the reviewer has shown in "Palestine and its Transformation," there are terraces at the north end of the Dead Sea much higher than 50 meters; and near the head of Wadi Kuram, in this same region, between Massaba and Nebi Musa, deposits, apparently of lacustrine origin, are found at a height of approximately 450 meters.

**Mindel-Riss Interglacial Epoch.** A long, dry period during which the Dead Sea fell to approximately the present level. Great erosion and much outpouring of lava.

**Riss Glacial Epoch.** Slight encroachment of the Mediterranean Sea, many lava flows. Slight expansion of the Dead Sea, formation of the

"middle terrace" in the deltas of various wadis. On physiographic grounds it seems to the reviewer open to question whether this terrace should be put at this time or much later.

Riis-Würm or last Interglacial Epoch. Mediterranean Sea at present level, climate approaching that of to-day.

Würm Glacial Epoch. No notable expansion of the Dead Sea. Formation of lowest terrace of the valleys, a conclusion which is open to question.

Post-Glacial Epoch. Uniform prevalence of conditions like those of to-day.

In the interpretation of rock geology, Dr. Blackenhorn is an expert, but when it comes to the interpretation of such physiographic phenomena as strands and terraces we are unable to accept his conclusions. In the first place he has failed to observe a large number of lacustrine strands which close study reveals at many points and at many altitudes around the Dead Sea. In the second place, he seems to have confused lacustrine and alluvial terraces in various places, and in the third place he has correlated terraces which apparently have no relation to one another. For instance, on page 139, when describing the Araba south of the Dead Sea, he describes a "Haupt Terrasse" with a height of 4 meters and a "Mittel Terrasse" with a height of one meter. The first of these terraces is assumed to have existed ever since the Mindel glacial epoch, and is correlated with a terrace which elsewhere is 150 meters high. He supposes the middle terrace to have originated during the Riis Glacial Epoch, and to have survived the vicissitudes of the Riis-Würm Interglacial Epoch, the Würm glacial epoch, and the succeeding period during which the climate is supposed to have remained in its present condition. Both of these terraces, it must be remembered, are in unconsolidated gravelly alluvium. It seems to the reviewer that they probably are the result of late post-glacial climatic pulsations.

In view of the diversity of results obtained by Dr. Blackenhorn and by other observers the whole question of the history of the Dead Sea from tertiary times onward

needs a far more thorough and systematic examination than it has yet received. This is the more necessary since the Dead Sea and Jordan Valley contain one of the best of all records of the Pleistocene history of the drier portions of the world. Dr. Blackenhorn's excellent study of the fundamental rock structure of the region is an admirable basis for such an examination. It is to be hoped that a further step may soon be taken and that by means of a careful instrumental survey of the old strands, terraces and deposits, the physical history of the region during the last hundred thousand years or so may be conclusively determined.

ELLSWORTH HUNTINGTON

### SPECIAL ARTICLES

#### THE PERFECT STAGE OF CYLINDROSPORIUM ON PRUNUS AVIUM

IN the fall of 1910, at the suggestion of Professor George F. Atkinson, the writer began a study of *Cylindrosporium*, as it occurs on species of *Prunus* in the region of Ithaca, N. Y., in order to discover the life history, and the relationship of the organism on the different hosts.

Several sweet cherry trees, which had been severely attacked by *Cylindrosporium* during the previous summer, were noted and the fallen leaves observed at intervals for the appearance of an ascogenous fungus. Early in March developing fruit bodies were noticed in abundance on many leaves, some of which were brought into the laboratory and placed in a moist chamber. After a few days at the room temperature of the laboratory many of the fruit bodies showed mature asci.

Subsequent observations showed that a stroma begins to develop under the *Cylindrosporium acervuli* about the last of August. About the time of leaf fall the acervulus is cut off from the underlying stroma by a compact layer of host tissue two or three cells thick, of thick-walled cells which surrounds the whole stroma and very soon turns black. Slow internal development of this stroma continues during the winter; and by the first of May mature asci and ascospores may be found.

Ascospores were taken from these fruit bodies and placed in drops of water on the leaves of *Prunus avium* seedlings in the greenhouse. This was repeated several times and resulted in every case in abundant infection, followed in a few days by typical *Cylindrosporium* acervuli. Later pure cultures were obtained from the ascospores, and the inoculation tests were repeated, using pure cultures, with similar results.

The study of the life history, relationship, etc., of the fungus is being continued, the results of which will be published in the near future.

The fungus belongs clearly with the Phacidaceae and is apparently an undescribed species of *Coccomyces*. The fruit body is imbedded in the tissue of the leaf, extending usually from one epidermis to the other. At maturity the wall of the fruit body bursts irregularly on the under side of the leaf, exposing the grayish-white hymenium beneath. The asci are club-shaped with a constricted, short-pointed apex. The spores are elongate, one- to three-celled, and borne in a fascicle in the end of the ascus.

Arthur,<sup>1</sup> in 1887, described what is probably the same ascogenous form (or closely related species) on plum leaves which were affected with *Cylindrosporium* the previous year. A similar ascogenous fungus was also mentioned and figured on dead leaves of *Prunus* by Pammel<sup>2</sup> in 1892, but in neither case was the fungus named or its connection with the *Cylindrosporium* stage proved.

The question now arises as to what species name should be applied to the perfect stage. One might employ the combination *Coccomyces padi* were it not for the fact that we are confronted with certain difficulties in the use of that name. In the first place we are not certain that the European form on *Prunus padus* is identical with the American form, though there is little doubt that a similar, if

not identical, ascigerous stage is present on the dead leaves of that species in Europe. Furthermore, several different names have been used for the prunicolous species of *Cylindrosporium* in North America and a similar difficulty would arise if a choice of one of these were attempted. In the second place, while a specific name already employed for an imperfect stage might be used for a new species there would always arise confusion as to what principle of nomenclature was followed in the combination if a name previously employed for an imperfect stage were used. According to the International code of nomenclature adopted at Brussels in 1910, relating to polymorphic fungi, a species name applied to the perfect stage has precedence over names applied to an imperfect stage. In order, therefore, to avoid any confusion, I propose for the perfect stage of the fungus on *Prunus avium* the name *Coccomyces hiemalis* n. sp. with the following brief diagnosis.

*Coccomyces hiemalis* n. sp.: *Ascomatibus sparsis* interdum subaggregatis, punctiformis, nigris, ovatis vel orbicularibus, primum clausis, deinde in lacinias plures acutas dehiscens; disco pallido carneo, 125–210  $\mu$  lat. ascis clavatis, crassiuscule stipitatis, 70–95  $\times$  11–14 octosporis, apice papillato; paraphysibus filiformibus, simplicibus aut ramosis, apice curvato; sporidiis linearibus 33–45  $\times$  2, 5–3, 5  $\mu$ , simplicibus aut 1–3 septatis.

#### ON THE HISTORY OF COTTONS AND COTTON WEEVILS

REFERRING to my first article on the Peruvian square-weevil,<sup>1</sup> in which were presented data relating to the origin of the cotton plant, it now seems possible to make certain well-founded deductions. The presence of the nearest wild relatives of *Gossypium* only in the New World indicates that the stock from

<sup>1</sup> Arthur, J. C., "Plum Leaf Fungus," N. Y. Agr. Exp. Sta., Rept. 5, 293–298, 1886.

<sup>2</sup> Pammel, L. H., "Spot Disease of Cherries," Iowa Agr. Exp. Sta., Bull 13, 55–66, 1891.

<sup>1</sup> *Journal of Economic Entomology*, April, 1911.

which these sprang was evolved in Antarctica and spread northward during the Mesozoic after both the African and Austromalaysian connections had been broken. South America was the last of the great land masses to be cut off from Antarctica, hence only in America do we find such nearly related but distinct types as *Ingenhousia* and *Cienfuegosia*. The Australian cottons have been isolated since the southward dispersal of the type which preceded *Gossypium* and which originated in the north. Hence they are found to be farther removed from the Asiatic and American true cottons than are the latter from each other, being properly separated under *Sturtia*. They represent more nearly the immediate type from which *Gossypium* s. str. sprang.

*Anthonomus* is a type of North American origin, where it was dominant during the Tertiary—Oligocene and Miocene. From some of its first waves of southward dispersal sprang the group to which belongs *Anthonomus vestitus*, which latter has developed on cotton alone in South America. From a later wave of southward dispersal sprang the *A. grandis* group, this species likewise developing on cotton alone, but originating in Central America and Mexico. Almost certainly one of the periodic separations between North and South America took place while the *A. grandis* group dispersal was in progress, thus cutting this species off from South America. During subsequent connections of the two continents no extensive dispersals of these groups occurred. This explains the fact that *A. vestitus* belongs to a group not represented in North America, and indicates the great probability that *A. grandis* does not occur in South America. It also explains the now quite evident fact that both of these weevils have no other food-plant than cotton, having originally developed on that plant.

From these points we may deduce that *A. vestitus* has probably attacked cotton in humid northwestern South America for upward of a million years, if not longer. It is therefore extremely probable that this species is not confined to Peru and Ecuador.

CHARLES H. T. TOWNSEND

## THE ASTRONOMICAL AND ASTROPHYSICAL SOCIETY OF AMERICA

THE fifteenth meeting of this society was held in Cleveland in connection with the American Association for the Advancement of Science, from December 31, 1912, to January 2, 1913. With the exception of the joint session with the American Mathematical Society and Sections A and B of the American Association for the Advancement of Science on Tuesday afternoon, December 31, the meetings were held in the recitation room of the department of astronomy of the Case School of Applied Science. The secretary of Section A has already reported on the joint meeting (see page 76 of this volume).

The time was so thoroughly filled with the program of papers that little opportunity was afforded for attendance of the meetings of the various sections of the association and the other affiliated societies, or for excursions about the city. Most of the members, however, visited the observatory of the Case School, where are housed an excellent almuercant, a zenith telescope and a transit instrument, and accepted the privilege of visiting the Warner & Swazey shops.

The following members were in attendance: Sebastian Albrecht, S. I. Bailey, L. A. Bauer, J. A. Brashear, E. W. Brown, C. A. Chant, W. A. Cogshall, W. S. Eichelberger, Philip Fox, William Gaertner, James Hartness, G. F. Hull, W. J. Humphreys, F. C. Jordan, N. A. Kent, Kurt Laves, T. A. Lawes, W. I. Milham, D. C. Miller, E. W. Morley, E. F. Nichols, J. A. Parkhurst, E. C. Pickering, J. S. Plaskett, W. F. Rigge, H. N. Russell, Frank Schlesinger, H. T. Stetson, R. M. Stewart, J. N. Stockwell, G. D. Swazey, W. R. Warner, F. P. Whitman, D. T. Wilson, H. C. Wilson, Anne S. Young, E. I. Yowell.

Visitors: G. L. Coyle, S. F. Cusick, Patrick Rafferty, J. I. Shannon.

The following were elected members of the society: W. O. Beal, J. R. Collins, Ralph E. DeLury, R. T. A. Innes, William H. Morton, Earl C. Slipher.

Abstracts of the 36 papers which were read follow in the order of presentation.

### *The Correction of Actinometer Measurements for Aqueous Depletion:* FRANK W. VERY.

Tables have been prepared for the approximate correction of actinometric observations with air masses and pressures of aqueous vapor as arguments. The first table of multiplying factors is

for sea level, and the second is for the conditions and altitude (1,780 meters) of Mount Wilson.

TABLE I

Air Mass	Pressure of Aqueous Vapor				
	1½ mm.	3 mm.	6 mm.	9 mm.	15 mm.
$e = \frac{1}{2}$	$F = 1.35$	1.40	1.52	1.63	1.86
1	1.65	1.76	2.02	2.28	2.80
2	2.18	2.35	2.66	2.97	3.60
3	2.60	2.80	3.18	3.53	4.22
4	2.99	3.21	3.58	3.96	4.71
5	3.39	3.66	4.05	4.42	5.15
6	3.69	4.09	4.54	4.88	5.56
7	4.03	4.50	4.97	5.29	5.93
8	4.40	4.91	5.43	5.75	6.25
9	4.74	5.35	5.95	6.22	6.60
10	5.10	5.83	6.43	6.73	6.95

TABLE II

Air Mass	Pressure of Aqueous Vapor				
	1½ mm.	3 mm.	6 mm.	9 mm.	15 mm.
$e = \frac{1}{2}$	$F = 1.70$	1.76	1.78	1.80	1.86
1	2.06	2.16	2.21	2.25	2.30
2	2.34	2.45	2.52	2.58	2.63
3	2.63	2.75	2.84	2.90	2.95
4	2.91	3.05	3.15	3.20	3.25

These tables have been used to get the value ( $A = FE$ ) of the solar radiation outside the atmosphere from observations published in Vol. 2 of the *Annals* of the Smithsonian Astrophysical Observatory. A random selection will illustrate the nature of the results.

TABLE III

Washington, D. C.			
Date	Aqueous Vapor, mm.	$A$	$A$ at Sun's Mean Dist.
Aug. 24, 03	14.66	3.204	3.255
Dec. 23, 03	3.30	2.878	2.770
May 28, 04	6.50	2.855	2.920
Oct. 21, 04	7.29	3.697	3.639
Jan. 9, 06	1.96	3.227	3.106
Mean.....			3.185 ±0.105
Mount Wilson			
Date	Aqueous Vapor, mm.	$A$	$A$ at Sun's Mean Dist.
Oct. 20, 06	1.59	3.602	3.547
June 7, 05	7.17	3.542	3.634
Aug. 22, 05	13.84	3.526	3.585
Mean.....			3.589 ±0.017

The data are very inadequate. The pressure of aqueous vapor is seldom recorded more than once a day, and in the absence of barometer readings I have been obliged to assume values of 760 mm. and 618 mm. for sea level and mountain, respectively. To do full justice to the method, it will be necessary to secure simultaneous observations of the distribution of aqueous vapor in the upper air by means of sounding balloon ascensions or high kite flights. No correction for atmospheric dust has been applied. The depression and the disagreement of the sea-level results are no doubt due principally to the irregular depletion by this ingredient of the lower air. This serious defect very nearly disappears on the mountain.

*Astronomy in the Civil Court*: W. F. RIGGE.

A short time ago a man was accused in the criminal court (Omaha, Nebraska) of having attempted to wreck a cottage and kill its inmates by means of a suitcase full of dynamite. The state produced only two witnesses, who said they had seen the accused carrying the suitcase near the time and place specified. They had just come from a church a mile away, in front of which they had posed for their photograph. The position of a prominent shadow in this picture enabled an astronomer to compute the exact minute of its exposure. As this was half an hour after the time at which the suitcase had been found the testimony of science eventually freed the prisoner from fifteen years in the penitentiary. It was confirmed by the measurements and computations of a second astronomer, and by a series of three photographs exposed at intervals of one minute on the second anniversary of the taking of the original picture.

*A Northern Durchmusterung*: E. C. PICKERING.

The Cape Photographic Durchmusterung gives the positions and photographic magnitudes of nearly half a million stars south of declination  $-20^\circ$ , thus covering about one third of the sky. This great work by Gill and Kapteyn is indispensable to any astronomer studying the southern stars.

One of the greatest needs of astronomy at the present time is the extension of this work to the North Pole. A plan has accordingly been prepared for taking the necessary photographs at Harvard, with the 16-inch Metcalf telescope, with curved plates, using those sensitive to the red, as well as to the blue rays. The photometric and photographic magnitudes, on a uniform scale, will be determined for a number of standard stars on

each plate. They will then be sent to Kapteyn, who will supervise their measurement and reduction. If the entire plan can be carried out, the catalogue will contain eight hundred thousand stars, or more, and will fill at least ten volumes of the *Harvard Annals*.

*The Scale of the Yerkes Actinometry:* J. A. PARKHURST.

A new determination of the absolute scale for the photographic magnitudes of the Actinometry indicates that the published scale may be too extended by an amount not exceeding six per cent. The original scale was obtained from sensitometer images impressed on the plates with exposures of 10 to 20 seconds. The star images had exposures of 5 and 25 minutes. An extended series of new sensitometer exposures ranging from 5 seconds to 34 minutes indicated that the gradation was steeper for the exposures of 5 minutes and longer, than for the exposures in the neighborhood of 10 seconds. No difference was found for exposures of 5 and 25 minutes, and this was confirmed by 422 pairs of images of white stars on the zone plates. The application of the correction of — 6 per cent. brings the magnitudes into better agreement with Harvard and leaves the differences with Göttingen the same in amount but with the sign changed.

*The Color Scale of the Yerkes Actinometry:* J. A. PARKHURST.

A calibration of the color-sensitive plates used in obtaining the "visual" magnitudes of the Actinometry makes it possible to express the varying effect of light of different wave-lengths in difference of stellar magnitude. The spectral intensity curve is nearly symmetrical and has its maximum at wave-length 5350. The absence of selective absorption in the U-V glass of the Zeiss doublet was shown by comparison of spectra taken direct and through the glass.

*On R Lyræ with a Three-prism Slit-spectrograph:* SEBASTIAN ALBRECHT.

This paper gave the results of a study of two series of three-prism spectrograms, twenty-five plates in all, taken at the Lick Observatory. Following is a summary of the principal results:

1. The radial velocity of the star is — 27.22 km. per sec.

2. No periodic variation of radial velocity was found. If such a variation exists, the double amplitude of variation must be less than  $1\frac{1}{2}$  km.

3. Wave-lengths were determined for about 600 spectrum lines, between  $\lambda$  4150 and  $\lambda$  4700  $\pm$ .

4. The individual spectrum lines showed no large periodic shifts.

5.  $H_{\alpha}$  showed definite variation in intensity, though the data available are insufficient to determine definite connection with phase of light-variation.

6. The wave-lengths of the lines in R Lyræ, a star of irregular light variations, are in good agreement with the wave-lengths of lines in the *M* type stars.

7. A preliminary test of this star for spectral type, according to the method published in the *Astrophysical Journal*, March, 1911, places it at a somewhat "later" type than *Mb*, the type assigned to it in the Draper Catalogue.

*A New Form of Printing Chronograph:* WILLIAM GAERTNER.

This paper described in detail an instrument for recording time in minutes, seconds and hundredths of seconds, printing the records in figures on a strip of paper. The instrument is used in connection with a clock or chronometer fitted with an electric seconds contact, which operates the minute and second type wheels and controls the speed of the 0.01 seconds wheel.

The minute and second wheels are rotated by two specially designed electro-magnets which operate on pawls and ratchet wheels of 60 teeth. The seconds wheel closes a circuit when it has made a full revolution and operates the magnet which shifts the minute wheel. Both wheels can be turned independently by hand and set to coincide with the clock. The wheel printing the 0.01 seconds is automatically set to zero by the clock circuit and control magnet.

The control of the hundredths of seconds is not made directly on the type wheel, but by means of a ratchet wheel of 100 teeth, and an iron pawl engaging in it. The ratchet wheel is driven by a separate weight driven clock work, regulated by an improved form of conical pendulum friction governor. This regulator is set to run a little fast. When it has gained 0.01 second the control magnet operated by the observing clock will disengage the pawl and drop it in the next tooth of the ratchet wheel, bringing the type wheel again in adjustment. In practise the governor is adjusted so that the regulator gains about  $1\frac{1}{2}$  second per hour and therefore the control will take place about every 24 seconds.

The printing of the time records is accomplished by an electro-magnet which operates the printing

hammers. A paper strip sufficiently long to take about 1,200 records passes between an ink ribbon and the printing wheels and is fed through two corrugated rollers which give the spacing between records. The same current operates the printing magnet and the electro-magnet which turns the spacing rollers. A mechanism at the same time gives a shift to the ink ribbon.

Samples of the records from the chronograph were exhibited.

*Circulation in the Solar Atmosphere as Indicated by Prominences:* FREDERICK SLOCUM.

This paper is based upon the study of 4,600 solar prominences of which over one third either by their form or movement indicate a horizontal circulation in the solar atmosphere. The results have been classified according to direction N. or S., heliocentric latitude, and height above the chromosphere. Illustrations were shown of the types of prominences used.

The conclusions from this investigation are given in the following summary: (1) Many prominences, by their shapes or movements, seem to indicate the existence of a horizontal current in the solar atmosphere. (2) This current may have opposite directions at different altitudes in the same locality. (3) It may change its direction just as the wind changes upon the earth. (4) In middle latitudes the average tendency for movement is toward the poles. (5) In high latitudes the average tendency for movement is toward the equator. (6) This tendency is much more marked in the northern than in the southern hemisphere. (7) From latitude  $10^\circ$  north to  $10^\circ$  south the average tendency is from north to south directly across the equator. (8) The prevailing directions mentioned above are the same for prominences of all heights. (9) Upon a rotating sphere the circulation is undoubtedly spiral. The observations used in the present investigation take account only of the north and south components. The east and west components may eventually be added by an extended series of radial velocity measures of prominences. (10) Observations upon prominences within  $5^\circ$  to  $10^\circ$  of the poles are unreliable, as a prominence approaching the pole spirally may project so as apparently to be moving away from the pole.

*Cosmical Magnetic Fields:* L. A. BAUER.

This paper was read at the joint meeting. For the abstract see page 76 of this volume.

(Opportunity is taken here to correct an error appearing in the abstract of Professor Bauer's

paper, "On the Cause of the Earth's Magnetic Field," *SCIENCE*, January 3, 1913, page 27. The sentence following the equations should read: These characteristic functions,  $f_x(u)$  and  $f_z(u)$ , show an increase, etc.)

*Preliminary Note on an Attempt to Detect the General Magnetic Field of the Sun:* G. E. HALE.

Read at the joint session (see page 76 of this volume).

*Visualizing the Sun's Way:* H. C. WILSON.

Two charts were exhibited showing the proper motions and radial velocities of 1,157 stars. The proper motions were taken from Boss's Preliminary General Catalogue and the radial velocities from unpublished records at the Lick Observatory. Chart No. 1 covers the hemisphere having its center at  $\alpha = 270^\circ$ ,  $\delta = +30^\circ$ , the approximate apex of the solar motion. Chart No. 2 covers the hemisphere having the solar antapex at its center. Stars having radial velocity of approach to the sun are represented by open circles, while those which are receding are indicated by black circles. The amount of the radial velocity is represented, upon an arbitrary scale, by lines parallel to the lines representing the proper motion. Chart No. 1 indicates quite clearly that the solar apex is somewhere in the vicinity of  $\alpha = 270^\circ$ ,  $\delta = +30^\circ$ , both by the general trend of the proper motions outward and by the prevalence of open circles near the center of the chart. Chart No. 2 shows equally well that the antapex is near  $\alpha = 90^\circ$ ,  $\delta = -30^\circ$ , by the prevailing blackness of the star images and the general inward trend of the proper motions.

*The Spectra of the Gaseous Nebulae:* ANNIE J. CANNON.

Of the 140 nebulae which have been announced to be gaseous, 50 were detected and 54 others have been confirmed from the examination of the Harvard photographs. An examination of 41 of the brightest has been made for the purpose of general classification. While at least three subdivisions of Class P of the Draper notation are indicated, it does not seem advisable at present to assign special designations to them.

The principal class is represented by N.G.C. 7662. The so-called chief nebular lines,  $\lambda 4959$  and  $\lambda 5007$ , are the strongest lines,  $\lambda 3726$  and  $\lambda 3729$  in the violet are extremely faint or invisible, while  $\lambda 3869$  and  $\lambda 4686$  are well marked. 28 out of the 41 nebulae so far studied appear to belong to this general class, although 17 differ from N.G.C. 7662 in having  $\lambda 4686$  absent, and

2 are peculiar in an increased intensity of  $\lambda$  4363. A broad bright band approximately at  $\lambda$  4363 was the strongest band in the spectrum of Nova Geminorum, No. 2, on November 9, 1912, and may be characteristic of the spectra of new stars when they become gaseous, as it is also very bright in the photographs of Nova Aræ and Nova Velorum.

A second class of the spectra of gaseous nebulae has a line in the violet, which is probably a blend of  $\lambda$  3726 and  $\lambda$  3729, for the strongest line, while  $\lambda$  3869 and  $\lambda$  4686 are absent, and the chief nebular lines  $\lambda$  4959 and  $\lambda$  5007 are barely visible. No. 418 of the Index Catalogue, DM. —12°.1172, is the only object so far found belonging to this class. Since  $\lambda$  3727 and  $\lambda$  5007 are both present in the spectrum of the Great Nebula of Orion, it may be intermediate between the two classes represented by N.G.C. 7662 and I.C. 418. A third division of gaseous nebulae has  $\lambda$  4686 for its strongest line. N.G.C. 40 is typical of this class, and one other  $\alpha = 19^{\circ} 0^m.5$ ,  $\delta = -6^{\circ} 8'$  (1900), similar to it, has been found. This class of nebula is of special interest, owing to a possible connection with the spectra of Class O, in which a bright band at the same approximate wave-length is the distinguishing feature. When an object is faint, it may show only the bright band 4686, and it would then be impossible to determine, from its photographic spectrum, whether it belonged to Class O or to the third division of gaseous nebulae. N.G.C. 40 was observed by Herschel, and a photographic chart plate shows its nebulous character.

For the purpose of comparison a composite photograph was exhibited showing the spectra of Sirius, of I.C. 418, N.G.C. 7662, Nova Geminorum II., on November 9, 1912, the same on March 13, 1912, H.R. 2583 typical of Class Ob and N.G.C. 40.

#### *Stellar Spectroscopic Notes:* WALTER S. ADAMS.

The following notes contain some of the recent results obtained in the course of the regular radial velocity work with the 60-inch reflector.

The seven stars following are spectroscopic binaries with large range in velocity.  $\xi$  *Arietis*, *Boss* 546, Mag. 5.6, Spectrum  $B_6$ . The range shown by the first three plates was 57 km. On a fourth plate two spectra were visible and measures of the separate components gave a relative velocity of 262 km. The spectra of the two stars are nearly identical. *Boss* 2484, Mag. 6.2, Spectrum  $A_1$ . The range shown by three plates 88 km. 2 *Comæ Berenicensis*, *Boss* 3150, Mag. 6.2, Spectrum  $A_1$ . The range shown by three plates 53 km. *Boss*

3540, Mag. 6.8, Spectrum  $A_0$  peculiar. Range shown by three plates 105 km. 16 *Sagittarii*, *Boss* 4613, Mag. 6.2, Spectrum  $B_1$ , peculiar. Range shown by three plates 86 km. Traces of a second spectrum are visible.  $\sigma$  *Aquilæ*, *Boss* 5018, Mag. 5.2, Spectrum  $B_1$ . Two spectra are visible on the first plate, one of the type  $B_2$  and the other  $B_1$ . The relative velocity of the two components on this plate is 367 km. *Boss* 5070, Mag. 5.8, Spectrum  $B_1$ . Range shown by three plates 138 km.

Two photographs of the spectrum of the star *Lalande* 15290, Mag. 8.2, Spectrum  $G_1$ , show that its radial velocity is the largest of any star observed to date in the northern sky. The spectrograms which were taken in April and November, 1912, give values of —243 and —241 km., respectively. A photograph of this star taken in December, 1910, with a temporary spectrograph gave an approximate velocity of —250 km. Its proper motion is 1".97 annually and its parallax is 0".045 according to the values summarized by Kapteya in Groningen Publications No. 24. Its velocity in space accordingly as referred to the sun is 318 km., a value only slightly inferior to that of 1830 Groombridge.

Observations of a number of the brighter stars in the  $\eta$  and  $\chi$  *Persei* clusters lead to the interesting conclusion that most of these stars have nearly the same radial velocity and apparently are moving together. The stars observed are as follows:

	Mag.	Spectrum	Mean Velocity
B.D. + 57°.494 .....	6.5	$A_1$	—44
+ 56°.438 .....	6.5	$B_6$	—40
+ 56°.470 .....	7.0	$B_2$	—43
+ 56°.471 .....	6.6	$B_1$	—43
<i>Boss</i> 519 .....	6.9	$B_3$	—46
B.D. + 56°.530 .....	6.9	$B_6$	—45
+ 56°.568 .....	6.7	$A_1$	—45
+ 55°.612 .....	6.3	$B_3$	—46

The velocity of *Boss* 519 is probably variable. The spectra of most of these stars belong to division  $c$  of Miss Maury's classification—that is, have relatively sharp lines. The average velocity is exceptionally high for stars of this type and this fact taken in connection with their proper motions and the similarity of their spectra makes it very probable that they form a true group. The star B.D. + 55°.598, Mag. 5.7, has a velocity of —18 km. as determined from one plate and should additional photographs show this velocity to be constant it would seem probable that the

star does not belong to the group. The proper motions of most of these stars have been measured recently by Van Maanen and found to be extremely small and their parallaxes are below the limits of error of measurement according to Kapteyn's results.

A comparison of three photographs of the spectrum of Nova Geminorum II. taken in August, September and November leads to the following conclusions: (1) The principal nebular bands are slightly more intense on the last photograph, while the hydrogen and helium lines remain very nearly constant. (2) A very marked change occurs in the line  $\lambda 4687$  of the principal series of hydrogen. On the August photograph it is very faint, while in November it is fully half as strong as the intensely bright band  $\lambda 4640$ . This line showed evidence of rapid variation on earlier photographs as well, gaining greatly in intensity between May 5 and May 10. Its behavior should prove of great value as bearing on the physical condition of the star. (3) Two other bands, one at  $\lambda 4522$  and the other at  $\lambda 4605$  are considerably stronger on the last photograph. (4) The widths of the bright bands have remained remarkably constant throughout the history of the Nova. Measures on the hydrogen, helium and nebular bands show no appreciable change from the photographs of April and May. The positions of the centers of the bands also remain as on earlier photographs, being displaced from one to two Angstroms toward longer wave-lengths. (5) All of the more prominent bright bands except those at  $\lambda 4522$ ,  $\lambda 4605$  and  $\lambda 4640$  have broad faint absorption bands nearly symmetrically placed upon them. In several cases the dark bands contain one or more narrow absorption lines. A remarkable case of this sort is the line at  $\lambda 4337.5$  which has been measured upon all of the photographs taken since March. The bright bands are terminated on either side by bright maxima, the violet member of which is the strongest on the plates of August and November. (6) In addition to the bright bands the spectrum of the star almost certainly shows an extremely faint continuous spectrum probably crossed by dark lines. The  $H$  line of calcium is seen as a dark line on the November photograph and yields a value of the radial velocity of about  $+5$  km.

From these considerations it is evident that the spectrum of this Nova and probably of other Novæ as well is by no means so simple in its later history as has sometimes been supposed. The

great width of the emission bands, the presence of well-defined selective absorption within them, the persistence of the displacement of their centers toward longer wave-lengths, as well as the marked variation in intensity of some of the important bands such as  $\lambda 4687$ , all go to show that the physical conditions present are the most complex, and must differ greatly from such as produce an ordinary nebular spectrum.

*Rate of Light Changes in Various Celestial Objects: S. I. BAILEY.*

A discussion of the variable stars in Messier 3 shows some examples of extraordinary rates of increase in light. This globular cluster is a faint hazy star of about the sixth magnitude to the naked eye. Its marvelous character is not suggested even in a small telescope. At Arequipa with an exposure of 100 minutes with the 13-inch Boyden Refractor about 1,200 stars were shown. These plates showed stars somewhat fainter than the 16th magnitude. Among these were found 137 variables among 900 stars actually examined for variability, or one in seven. The total number of stars in the cluster is very great. On a plate made by Ritchey on Mt. Wilson with the 60-inch reflector giving an exposure of four hours not less than 30,000 stars are seen, if we include the central mass where an exact count is impossible. Among the variables found in this cluster the maximum rate of increase in four cases appears to be more than six magnitudes an hour. The mean maximum rate of increase of all the variables is about two and a half magnitudes an hour.

It is doubtful whether any other celestial object has so great a known rate of variation as six magnitudes an hour, although it seems probable that this rate may be exceeded in the case of Novæ. Except for Novæ great rates of change appear to be rare.  $\chi$  Cygni has a range of nearly ten magnitudes, but this enormous change takes place during so long a time that the rate per hour is only a fraction of a magnitude. Eros has perhaps the shortest period of a known object. From one maximum to the following is only about two and a half hours. The range may be a magnitude or more at times, and the light curve closely resembles a sine curve. Its maximum rate of change is probably never more than two or three magnitudes per hour. Some of the Algol variables change very rapidly.  $U$  Cephei and  $W$  Delphini are good examples. The rate per hour, however, of any known Algol star does not exceed two or three magnitudes per hour.

*Relative Intensity of Prismatic and Grating Spectra:* J. S. PLASKETT.

The grating spectrograph used was briefly described at the last meeting and is arranged to be used in the Littrow form, giving linear dispersion 17.5 Å per mm. and with incident and diffracted pencils 30° apart giving 33.0 Å per mm. A half prism silvered on the back can be substituted for the grating in the Littrow form, giving the same dispersion at  $H_\gamma$ . Comparisons of intensity were made with the Ottawa three-prism and one-prism spectrographs, giving practically the same dispersions at  $H_\gamma$ . Spectra of the sun and of different stars agree well in showing: (1) The grating does not diffract more than 30 per cent. of the incident light and the spectra are correspondingly weak. (2) The diffraction star spectra are practically uniform in intensity between  $\lambda$  4800 and  $\lambda$  3850. (3) Prismatic spectra are relatively stronger in the blue and weaker in the violet than diffraction spectra. (4) Diffraction spectra become equal in intensity to the three-prism spectra at  $\lambda$  4250, to one and to half-prism spectra at  $\lambda$  3970. Above these regions prismatic are stronger, below weaker than diffraction spectra. (5) The great loss of light by absorption in prisms is shown by comparison of one- and three-prism spectra. The former are more than twice as strong between  $H_\beta$  and  $H_\gamma$ , three times at  $\lambda$  4250, seven times at  $\lambda$  4150, fifteen at  $H_\delta$ .

A diffraction star spectrograph would be of value in the ultra-violet, when spectra of uniform intensity from  $H_\beta$  down were required, and in the red end where prismatic spectra are unduly compressed.

*A New Form of Clock Synchronization:* R. MELDRUM STEWART.

The form of synchronization described is adapted to the case where both the synchronized and the synchronizing clocks control electric circuits. In the particular case where it is applied at the Dominion Observatory the synchronizing clock controls a circuit which is closed every alternate second, while that controlled by the synchronized clock is closed for one second every minute, for the purpose of operating electric "minute jumpers." Each of these circuits operates a relay, and it is the coincidence of the opening of the relays which forms the automatic test of synchronism, which takes place every minute. In addition there is used a neutrally adjusted polar relay; the circuit from a local battery is so arranged that, once a minute, while

the relay operated by the controlled clock is closed, current flows through the winding of the polar relay, the direction of the current depending on the position of the armature of the relay operated by the synchronizing clock. Thus, at the instant of the opening of the relay operated by the controlled clock, the position of the armature of the polar relay depends on whether the "synchronizing" relay is open or closed (that is, on whether the controlled clock is slow or fast); and since the polar relay is neutrally adjusted, it will remain in the same position until current next flows through it, *i. e.*, until the next even minute. As soon as the relay operated by the controlled clock has opened, its back contact is utilized, in series with the points of the polar relay, to send a current through one or other of two magnets in the clock case, and so to either add to or remove from the pendulum a small weight, so as to accelerate or retard the clock for the following minute. At the end of the minute the automatic comparison is again made, and the clock again accelerated or retarded as required.

The controlled clocks are not particularly good timekeepers, and are exposed to considerable vicissitudes of temperature; to ensure satisfaction the correcting weights are made capable of taking care of a variation in rate of 8 or 10 seconds per day; the synchronization is in this case effective to within about a hundredth of a second. In the case of a high-grade clock very much smaller correcting weights could be used, and the interval between the automatic comparisons could be increased to perhaps an hour.

The principal advantage of this type of synchronization is that there is no possibility of stopping the controlled clock by interference with the synchronizing current, an advantage which, so far as I am aware, is not shared by any other method.

*An Investigation of the 9.4-inch Photographic Objective of the Shattuck Observatory:* H. T. STETSON.

The original 9.4-inch visual lens by Alvan Clark has been made convertible into a photographic by the substitution of a new flint, giving a focal length of 10 feet 6 inches. Measurements of extra focal plates taken after Hartmann's method for determining aberration errors show extreme variation in the focus to be less than one part in 3,000 for the same wave-length. The greatest irregularities lie in zones of 55 cm. and 85 cm. radii, where

there is marked shortening of the focus. Computation of the "criterion" constant gives  $T = 0.33$ , placing the quality well within the highest class.

The mean diameter of the confusion disk, when expressed in seconds of arc, becomes  $0''.69$  as against  $0''.45$  for the 40-inch Yerkes. The theoretical resolving power of a 9.4-inch is  $0''.52$ , whereas for the 40-inch it is  $0''.12$ . It is suggested that a criterion to best represent the quality of the optical work should involve this constant for any given aperture. This would appear to favor the quality of the smaller lens. This ratio might well be called a "coefficient of resolution."

*On the Luminous Efficiency and Color-index of a Black Body at Different Temperatures:* HENRY NORRIS RUSSELL.

The curves of spectral sensitiveness given by Parkhurst in his "Yerkes Actinometry" (with the addition of certain data very kindly communicated by Professor Parkhurst) make it possible to compute the luminous efficiency of a body radiating according to Planck's law at any temperature, that is, the ratio of its actual visual or photographic brightness to that of a body radiating the same amount of energy, but all of the wave-length of greatest visual or photographic efficiency. The results here given are provisional, and may be somewhat altered when fuller data regarding the spectral sensitiveness become available.

The visual luminous efficiency is a maximum for a temperature of about  $7,500^\circ$ , its value being 0.11. The visual surface brightness, on the Yerkes scale, varies with the temperature very nearly as the intensity of monochromatic radiation of wave-length  $0.541 \mu$ , and the photographic surface brightness like that of wave-length  $0.428 \mu$ , the deviations averaging less than  $0.07$  for temperatures between  $2,000^\circ$  and  $25,000^\circ$ . The color-index can be still more closely represented by the formula

$$\text{Phot.} - \text{Vis.} = \frac{7500^\circ}{T} - 0.07,$$

the residuals averaging only  $0.02$ .

For the Harvard visual and photographic observations the mean effective wave-lengths appear to be  $0.516 \mu$  and  $0.419 \mu$ , and the color-index is given by the equation

$$\text{Phot.} - \text{Vis.} = \frac{6900^\circ}{T} - 0.60.$$

The "black-body" temperatures corresponding to the color indices of stars of the various spectral types may now be determined. The Harvard

and Yerkes data give effective temperatures (ranging from  $23,000^\circ$  for Class  $B_0$  to  $3,100^\circ$  for Class  $M$  and  $2,300^\circ$  for Class  $N$ ), which are in excellent agreement with one another and with the previous determinations of Wilsing and Scheiner by visual spectro-photometric methods.

It appears also that the relative visual surface brightness of any two "black bodies" at different temperatures, if expressed in stellar magnitudes, should be 3.8 times the relative color-index on the Yerkes scale, or 4.3 times the color-index on the Harvard scale. The luminous efficiency is almost constant for color-indices between 0.0 (Sp.  $A$ ) and 0.7 (Sp.  $G$ ), but falls off rapidly for bodies at lower temperatures.

If these results, which are strictly true only for theoretically perfect radiators, apply approximately to the actual stars, and we could measure the brightness of the latter by means of their whole energy radiation, instead of a narrow spectral region, stars of Class  $K$  would seem about twice as bright, those of Class  $M$  four times as bright and of Class  $N$  more than twenty times as bright as they do now, in comparison with stars of Classes  $A$  to  $G$ . This would profoundly modify our estimates of the relative abundance of stars of different spectral types.

*The Eclipsing Binary  $\epsilon$  Aurigæ:* HARLOW SHAPLEY.

More than five thousand observations of the variable star  $\epsilon$  Aurigæ, made by Schmidt throughout the interval from 1843 to 1884, have been studied by Ludendorff, who deduces a period of light variation of 27.1 years and a light curve similar to those of certain eclipsing variables. Only three minima have occurred since the discovery of the light fluctuation by Fritsch in 1821. A study of the light curve by the writer shows that the observations can be satisfactorily represented by the eclipse theory. An accurate orbit is not possible, notwithstanding the large number of observations, but limiting sets of elements have been derived. The eclipse is total—the small bright star being completely hidden for more than a year behind the faint companion, whose volume is one thousand times the greater. The component stars are distantly separated. The mean density of the smaller component, if the masses are approximately equal, is not unusual in comparison to the densities already found for  $W$  Crucis and  $RZ$  Ophiuchi, whose periods of 198 and 262 days, respectively, are the longest heretofore known. The density of the big com-

panion, however, is about one millionth that of the atmosphere at the earth's surface. This greatly surpasses the rarity of any other known eclipsing star, but even then must be considered stellar rather than nebular. The sun extended to Jupiter's orbit would not be so dense as this, and seen from a neighboring star would certainly appear as a stellar point. Except near the limb, the larger component will be perfectly opaque. Through the center of the star the extinction must be nearly 40 magnitudes, if the mass is taken equal to the sun's mass. To allow for the translucence near the beginning and end of eclipse, the relative radii of the stars must be reduced still further, which would tend to make the density of the smaller star entirely normal without materially diminishing the density of the large component. The elements of the best orbit, which allowed for darkening to zero at the limb, are as follows: ratio of stellar radii, 0.10; inclination,  $77^{\circ}.0$ ; radius of large star (distance of centers, unity),  $0.397$ ; light of each component, 0.50; relative surface brightness, 0.01; hypothetical secondary minimum,  $0^m.004$ ; "equal-mass" densities,  $2.4 \times 10^{-2}$  and  $2.4 \times 10^{-6}$ .

Harvard classes the spectrum as  $F_3p$ . Ludendorff finds peculiarities in the radial velocity, and is making a detailed spectroscopic study of the system.

#### *Film Distortions on Small Photographic Plates:* F. E. ROSS.

By means of a reseau, tests were made of the film distortions on the small photographic plates used in the photographic zenith tube at Gaithersburg, Md.

The cut Lumiere Sigma plates are 37 mm. long by 27 mm. wide.; in all forty plates were measured, of which 20 were dried in air in the usual way, and 20 were immersed in alcohol before drying. Distortions in only one coordinate, the plates' length, were measured. The air-dried plates showed large, irregular distortions. The probable error of a measured 2 mm. space was  $\pm 1.5 \mu$ ; of a 22 mm. space,  $9.6 \mu$ . For larger distances the probable error was somewhat smaller. The corresponding probable errors of alcohol-dried plates were  $0.7 \mu$  and  $2.7 \mu$ , respectively. The probable error of an average distance on air-dried plates was  $6.5 \mu$ ; on alcohol-dried plates  $1.4 \mu$ .

The maximum distortion observed on an air-dried plate was  $49 \mu$ ; on an alcohol-dried plate  $10 \mu$ .

Air-dried plates always showed an expansion

over about three fourths its distance from the center. At this point the expansion, which amounted to  $19 \mu$ , ceased, but the irregularities became a maximum.

No certain expansion of the alcohol-dried plates could be detected. Air-dried plates which showed unusually large distortions were resoaked in water, dried in air and remeasured. The distortions were found to have been notably changed, in both distribution and amount. They were again well soaked and measured while wet. The distortions were found to have disappeared. Other air-dried plates showing large distortions were resoaked and redried in alcohol. The distortions disappeared in this case also.

#### *Some Effects of Radiation upon Astronomical Instruments:* F. E. ROSS.

Read, but no abstract was submitted.

#### *Recent Progress in the Theory of the Galilean Satellites of Jupiter:* KURT LAVES.

The paper is a part of a report concerning the Theory of Satellites in the Solar System, which will appear in Vol. VI. of the "Encyclopaedie der Math. Wissenschaften," published by the Academy of Sciences of Göttingen.

The modern investigations of de Sitter, Cookson, Sampson and others were considered, and attention was drawn to the fact that the old Laplace-Souillard theory is inadequate from a modern standpoint.

#### *The Solar Rotation in 1912:* J. S. PLASKETT.

Two series of rotation plates were obtained in 1912, though with great difficulty, owing to cloudy and hazy weather. The first of these series, center at  $\lambda 5600$ , the special region allotted to Ottawa, was obtained during June, and the second, center at  $\lambda 4250$ , the general region, during October. The first series, consisting of 25 spectra at each of the latitudes  $0^{\circ}$ ,  $15^{\circ}$ ,  $30^{\circ}$ ,  $45^{\circ}$ ,  $60^{\circ}$ ,  $75^{\circ}$ ,  $80^{\circ}$ ,  $85^{\circ}$ , was measured and reduced by the writer, and the velocity values obtained are well expressed by a formula of the Faye type.

$$V = (1.431 + 0.563 \cos^2 \phi) \cos \phi,$$

where  $V$  is the linear velocity in kilometers per second and  $\phi$  the heliographic latitude. The coefficients of this formula lie between those of the two series obtained in 1911 and the observed values for the two years are in good agreement, the only differences of any magnitude being at latitudes  $45^{\circ}$  and  $75^{\circ}$ , where the 1912 value is about 0.04 km. per second lower. The measurement and reduction of the other series will likely give defi-

nite information as to the best value of the coefficients of the formula and as to the discrepancy at the two latitudes.

*Orbital Planes of Binaries:* JOHN M. POOR.

The paper gave a preliminary statement in regard to a statistical method of investigating the parallelism of orbital planes of binary stars to any particular plane in space.

The several attacks upon the problem of determining whether the orbital planes of binary stars are parallel to any particular plane in space have led to no very positive indications that such parallelism exists in the case of the best determined orbits of binary stars.

If such parallelism exists it ought to be indicated in a statistical study of measures of binary stars by the systematic variation in magnitude for different parts of the sky of the correlation coefficient expressing the relation between position angle and distance of the doubles in a limited area of the celestial sphere. As this problem is more easily solved in rectangular than in polar coordinates, it may be put in the form of finding the correlation between  $s \cdot \sin P (=x)$  and  $s \cdot \cos P (=y)$ .

With a view to making a study of this question along these lines the necessary computations have been begun at the Shattuck Observatory, though a sufficient number of correlation surfaces has not yet been computed to allow conclusions to be drawn.

It is hoped that double star observers to whose attention this preliminary statement may come will cooperate by furnishing the writer with lists of their observations published since the appearance of Burnham's General Catalogue in order that the final computations may be based on as large an amount of material as possible.

*On Climatic Changes and the Cause of Ice Ages:*  
W. J. HUMPHREYS.

Numerous geological records give evidence of great climatic changes in the past, culminating at times in excessive heat and aridity and at other times in extreme cold and corresponding precipitation. It appears too that the great climatic changes were simultaneous and in the same sense the world over—warmer everywhere or colder everywhere. Hence, whatever the chief cause of these effects, it must have been world-wide.

Certain variations of long duration in the energy output of the sun would meet the above conditions, but the cause of such variations is not apparent nor is there other evidence that they ever actually

took place. Hence it seems well to seek for some general terrestrial cause of climatic change—for something in or of the atmosphere.

More or less continuous pyrheliometric records since 1880 show marked deficiencies in the amount of solar radiation received at the surface of the earth during the years 1884, 1885, 1886, 1903 and since June, 1912. The first of these periods followed the explosion of Krakatoa, the second the explosion of Mount Pelee and the third that of Katmai in Alaska. The only other minimum of importance, about half as great as those just mentioned, occurred in 1891 and presumably was also connected with a volcanic explosion.

Now the fine volcanic dust, roughly one micron in diameter, when thrown into the isothermal region of the atmosphere must settle slowly, since it is above the reach of clouds, and spread over all parts of the earth, as we know it did after each of the above-mentioned volcanic explosions. Further, the fine dust *scatters* the short wave-length solar radiation to a much greater extent than it does the relatively long wave-length earth radiation. In other words, earth radiation gets out through this enveloping layer of dust much better than solar radiation can get in. Hence the final equilibrium temperature of the earth as a whole, other things being equal, necessarily is lowered by the presence of a dust veil in the upper atmosphere. In the cases cited above the decrease of insolation seemed sufficient, if long continued, even to bring on an "ice age."

During the geological past there have been several periods of great volcanic activity with intervening ages of volcanic quiescence, just as there have also been ages that were warm and dry alternating with others that were cold and wet.

From the above considerations it is suggested that the alternate presence and absence, each for long periods, of volcanic dust in the high atmosphere may have been an important if not even the controlling factor in bringing about the great climatic changes of which geological records furnish abundant proof.

*Photographic Magnitudes of the Brighter Stars of the Polar Sequence:* FREDERICK H. SEARES.

The investigation of the magnitude scale of the Polar Sequence previously reported has been extended by photographing the brighter stars with diaphragms and screens producing apparent magnitudes between 10.5 and 15.5. The actual magnitudes were found by comparison with the fainter stars for which the scale had previously been

established. The results for any given diaphragm or screen establish a scale for the bright stars which should be homogeneous with the adopted scale for the faint stars, and, as far as the slope is concerned, independent of the reduction constant of the diaphragm. With one exception, the results for all the diaphragms and screens used are in substantial agreement, and show a mean divergence between Mt. Wilson and Harvard expressed by

$$\text{Mt. W.} - \text{H.} = +0^m.33 + 0^m.075(M - 10.5).$$

The formula holds between magnitudes 2 and 10.5. From 10.5 to 15.5 the scales are parallel, with the constant difference  $+0^m.33$ . The Mt. Wilson results agree closely with those of Parkhurst and Schwarzschild, which extend from magnitude 4.0 to 7.5.

*The Photographic and Visual Light-curves of RR Draconis:* FREDERICK H. SEARES.

At the fourteenth meeting of the society an announcement was made concerning the photographic variation of the Algol star *RR Draconis*. The eclipse is necessarily that of a bright object by a larger and fainter companion. The relative amounts of light are approximately as 32 to 1, and probably the larger object is the redder of the two. The photographic variation should therefore exceed the visual. This hypothesis was tested by photographing the star upon ordinary and isochromatic plates, the latter being used in connection with a yellow filter. The photographic and photovisual magnitudes of the comparison stars were determined by the use of diaphragms, the zero points of both scales being fixed by comparisons with the Harvard Polar Sequence. The greater photographic range is clearly shown. The results are

	Photo-graphic	Photo-visual	Color-Index
Maximum ....	9.64	9.98	- 0.34
Minimum ....	13.46	13.23	+ 0.23
Amplitude ....	3.82	3.25	0.57

The epochs of photographic and photovisual minima are probably the same. The maximum difference permitted by the present series of measures is 0.002 day, the photovisual minimum following the photographic.

*Some Recent Changes in the Spectrum of Nova Geminorum No. 2:* R. H. CURTISS.

On December 4, 1912, Nova Geminorum No. 2 was found to be passing through a period of marked light recovery. Its brightness, 7.5 magnitude, was identical with its former value seven

months previous or about eight weeks after discovery. During two weeks following December 8 the Nova faded rapidly down to magnitude 8.3. Visually the Nova was of a decided greenish-blue color during this period. The spectrum, however, underwent some marked changes.

At the brighter phase of the Nova's recovery the hydrogen lines and  $\lambda 4635$  had developed greatly in strength and intensity, but with declining light the nebular lines had become the strongest feature of the spectrum. Our observations indicate that the nebular lines actually gained in brightness or at least held their own while the total light of the star waned, but during the same interval the hydrogen lines faded rapidly.

Radial velocities from the dark H line of calcium agree with the value of ten kilometers per sec. positive, obtained shortly after the Nova's discovery.

*Do the Declinations of the Accepted Fundamental Catalogues Represent the True Positions of the Stars?* W. S. EICHELBERGER.

From two papers presented at the Ottawa meeting by F. B. Littell, on the work of the 6-inch transit circle, and on the work of the altazimuth at the Naval Observatory it appears that the declinations of the stars in Boss's General Catalogue culminating south of the Washington zenith require a correction of about  $+0^{\circ}.5$ .

This result is confirmed by the results in the volume of the Greenwich Observations for 1908, and the results obtained with the 9-inch transit circle of the Naval Observatory. Further, the 9-inch results show a practically constant correction from declination  $-30^{\circ}$  to declination  $+45^{\circ}$ , a rapid but nearly uniform decrease in the size of the correction from declination  $+45^{\circ}$  to declination  $+60^{\circ}$  and a nearly zero correction from that point to the pole. The rapidly changing correction a few degrees north of the zenith with a constant correction through the same zenith-distances south of the zenith would indicate that the fault can hardly be in the instrument. Can it be in the declinations of the fundamental catalogue?

If there is a discontinuity at the zenith in the determination of declinations at the various European observatories due either to the instrument or to the observer, such an error as supposed may have been introduced into the fundamental catalogues.

The following table, giving the differences between the declinations of three pairs of Pulkowa and Greenwich Catalogues, shows that such a discontinuity exists at least in some of the catalogues.

Decl.	No. Stars	$P_{45}-G_{45}$	Decl.	No. Stars	$P_{65}-G_{12}$	Decl.	No. Stars	$P_{85}-G_{80}$
71° to 65°	10	-0.03	72° to 65°	15	-0.08	72° to 63°	16	+0.15
65° to 61°	8	-0.13	64 to 60	10	-0.10	63 to 60	10	+0.24
Pulk. Zen.								
60° to 55°	13	+0.03	60 to 55	14	-0.63	60 to 56	12	+0.20
55° to 51°.5	6	-0.11	55 to 51.5	11	-0.62	56 to 51.5	13	+0.16
Green. Zen.								
51°.5 to 45°	19	-0.46	51.5 to 46	13	-0.79	50 to 45	18	+0.06
45° to 40°	15	-0.44	46 to 41	14	-0.99	45 to 40	18	-0.07
			41 to 35	14	-0.81			

A discontinuity at the zenith of about 0".5 is indicated in the Pulkowa Catalogue of 1865, and another of about 0".4 in the Greenwich Catalogue of 1845.

About half the circumpolars at Pulkowa culminate south of the zenith at their upper transit, and these should give a different latitude from those that culminate north of the zenith at their upper transit, if there is a discontinuity at the zenith. Therefore all the circumpolar observations of the above-mentioned Pulkowa Catalogues were rediscussed to obtain new corrections to the adopted latitude and refraction, introducing into the equations of condition a term ( $z$ ) to allow for the discontinuity at the zenith.

In the 1845 catalogue all the 110 circumpolars were included in the discussion instead of restricting oneself to the 43 used for a similar purpose in the introduction of that catalogue, and in the 1865 catalogue all of Gylden's zenith distances were increased 0".15 to correct for the relative personal equation of Gylden and Nyrén.

The results of this rediscussion of the Pulkowa observations are as follows:

$Z$  (Decl. south of zenith relatively too small)

1845 .....	+ 0".09	± 0".14
1865 .....	+ 0".37	± 0".10
1885 .....	+ 0".12	± 0".08
	Refraction Constant	Refraction Constant of Catalogue
1845 .... 57".47	± 0".064	57".56
1865 .... 57".45	± 0".045	57".56
1885 .... 57".38	± 0".035	57".37
	Latitude	Latitude of Catalogue
1845 .... 59° 46'	18".75	± 0".10 18".67
1865 ....	18".67	± 0".07 18".54
1885 ....	18".55	± 0".06 18".54

These values of the constants of reduction give the following corrections to the published declinations:

Decl.	1845	1865	1885
50°	+0.14	+0.33	+0.07
25	+0.20	+0.38	+0.07
0	+0.29	+0.50	+0.06
-25	+1.13	+1.54	-0.03

#### Orbit of the Spectroscopic Binary $\pi^5$ Orionis:

OLIVER J. LEE.

The variable velocity of the star  $\pi^5$  Orionis was announced by Frost and Adams with measures of seven three-prism plates in the *Astrophysical Journal*, 17: 151, 1903.

The following elements have been derived from these measures and from the writer's measures on fifty-seven one-prism plates taken with the Bruce spectrograph in the interval 1907-12:

Period .....	3.70045 days
Eccentricity .....	0.051
Longitude of periastron ....	84°
Semi-amplitude of oscillation .	58.6 km.
Velocity of system .....	+ 23.7 km.
$a \sin i$ .....	2,978,000 km.
Time of periastron passage ..	1907 Dec. 8.83
	or J.D. 2,417,918.83

#### The Expression of Pivot Errors by a Formula: R. MELDRUM STEWART.

Even the best measurements of pivot errors of a meridian circle or transit instrument are of course affected by accidental errors, and in the case of fairly good pivots these are no doubt larger than the actual deviations of the pivots from a smooth curve. It then becomes a question what pivot corrections should be adopted both for the positions in which the errors have been observed and for intermediate positions. In a recent series of measurements at the Dominion Observatory it was found that a good representation could be obtained by the use of a Fourier series, and it seems probable that the values so adopted are more accurate than the actual observed values.

It is evident that a Fourier series can be made to represent the observed values to any required

degree of accuracy; for example, the use of 72 unknowns would reproduce the observed values exactly, in the case where the intervals are  $5^\circ$ . Since, however, these observed values contain errors of measurement, it is probable that a more exact representation of the actual errors will be obtained by omitting the terms with small coefficients; if this be granted, the number of terms to be retained may in any particular case be decided by a computation of the probable error of a single observation. As several independent measurements of the pivot errors are usually made in a series, the probable error of a single observation may be computed directly from the residuals; if now we have a formula which is assumed to represent the actual pivot errors, the differences between the observed values and those computed from the formula may be used to form another probable error; the relative magnitude of these two probable errors will furnish a criterion as to the number of terms required in the formula. The freedom of the residuals from any systematic tendency will of course furnish the final test as to whether or not the formula is suitable.

In the actual determination referred to, which was made by the microscopic method, eight complete measurements were made; the probable error of a pair of microscope pointings (treated as a single observation) was found to be 0.0015 sec.; four terms of the Fourier expansion were found to be sufficient to reduce the computed probable error to the same value, and the resulting formula was adopted as definitive. This formula, expressing the necessary corrections to the observed colimation, was

$$\begin{aligned}\Delta c = & 0^{\circ}.0010 \cos (2\theta - 185^{\circ} 29') \\ & + 0^{\circ}.0117 \cos (3\theta - 3^{\circ} 17') \\ & + 0^{\circ}.0021 \cos (4\theta - 59^{\circ} 45') \\ & + 0^{\circ}.0008 \cos (5\theta - 121^{\circ} 58'),\end{aligned}$$

$\theta$  being the zenith distance. The residuals from the formula were satisfactorily small (in no case exceeding 0.002 sec.) and appeared to be purely accidental.

Values of the formula were computed for different zenith distances, and from these a table was prepared giving the zenith distances at which the value of  $\Delta c$  changed from one unit (in terms of 0.001 sec.) to the next; it is this table which is used in the reduction of transits.

*The Variable RV Capricorni*: S. D. TOWNLEY.

The variability of *RV Capricorni* was discovered by Götz in 1905. From fourteen photographic

observations scattered over an interval of five years he deduced a light curve of the Algol type. Seares and Haynes observed the star in 1906 and found a light variation of the antalgol type, with an approximate period of  $10^h 44^m.6$ . The star is classed as an antalgol by Hartwig, and Seares's epoch and period are used in computing the ephemeris.

During the summer and fall just past *RV Capricorni* was one of a list of variables observed by the writer with the 12-inch refractor and Rumford photometer of the Lick Observatory, the use of which was kindly granted by Director Campbell. Three well-determined maxima were obtained and these show that the Seares ephemeris now needs a correction of about  $3^h 10^m$ —the observed maxima coming that much before the computed.

By comparing a well-determined maximum obtained on October 11, 1912, with the first one obtained by Seares, August 13, 1906, a period of 0<sup>d</sup>.447573 has been derived, while the period determined by Seares is 0<sup>d</sup>.4476, which is therefore correct to the number of decimals given.

The observations show conclusively that this star is not of the Algol type, but there is perhaps some question as to whether it belongs to the antalgol or to the cluster type. Additional observations near minimum brightness, which I hope to obtain next summer, will be necessary to decide this point.

#### *Notes on the Real Brightness of Variable Stars:*

HENRY NORRIS RUSSELL.

The number of variables and of stars having peculiar spectra contained in Boss's Preliminary General Catalogue is large enough to enable an approximate estimate of their mean distance and real brightness to be made by the method of parallactic motion. Assuming that the sun is moving towards 18 h.,  $+30^\circ$  at 19 km. per second, the following values have been found, in the usual way, from the data of Boss and Campbell, for the parallactic motion  $M$ , the mean proper-motion  $\tau$  at right angles to the parallactic motion, the mean parallax  $\pi$ , the mean peculiar velocity— $r$  km. at right angles to the line of sight and the solar motion, and  $\rho$  in the line of sight, and finally the absolute magnitudes corresponding to the mean observed magnitude and mean parallax. Data for three groups of stars selected at random from Campbell's list of stars of Class *B* are added to test the value of the method for small groups, and some of the results of Campbell for large numbers of stars are added for comparison.

Objects	No.	Magnitude		$M$	$\tau$	$\pi$	$\tau$ km., km.	$\rho$ km.	Abs. Max.	Mag. Min.
		Max.	Min.							
Cepheid variables	13	4.3	5.1	0.015	0.007	0.004	8	9	-2.8	-2.0
Long-period variables	12	4.5	9.4	0.048	0.073	0.012	28		-0.1	+4.8
Irregular variables (Spectrum $M$ )	11	3.7	4.9	0.060	0.042	0.015	13		-0.4	+0.8
Stars of Sp. O to O <sub>6</sub>	24	4.95		0.016	0.006	0.004	7		-2.0	
Stars whose spectrum shows bright hydrogen lines	50	4.53		0.028	0.009	0.007	6		-1.3	
Random groups of stars of spectra B to B <sub>5</sub>	12	3.9		0.024	0.009	0.006	7	5	-2.2	
	11	3.7		0.036	0.007	0.009	4	6	-1.5	
	11	3.7		0.043	0.011	0.010	5	6	-1.3	

## Campbell's Results

Spectrum $B$	180	4.07	0.008	0.006	6.2	-2.1
$F$	180	(4.3)	0.108	0.035	14.4	(+2.0)
$G$	118	(4.3)	0.075	0.022	15.9	(+1.0)
$M$	71	(4.3)	0.038	0.011	17.1	(-0.5)

The variable stars of spectrum  $M$  appear to be much like the general run of stars of this spectral class in distance, peculiar velocity and (at maximum) in brightness, being then about 100 times as bright as the sun. At minimum, the average long-period variable seems to be comparable with the sun in brightness.

Stars of Class  $B$ , showing bright hydrogen lines, do not differ materially in distance, brightness or peculiar velocity from those that do not, and stars of spectrum  $O$  are but little farther away or brighter.

The Cepheid variables, on the contrary, are very much farther away, brighter and more slowly moving than most stars of Classes  $F$  or  $G$ , and closely resemble the Orion stars in all these respects, and also in their strong condensation toward the Milky Way—so much so as to suggest some real relation between them. Even at minimum, these stars average some 400 times as bright as the sun. If they are comparable with it in surface brightness, as seems very probable, their diameters must be at least ten times the sun's—far larger than their spectroscopic orbits. If their average density was less than 1/1200 that of the sun, their companions would collide with them at periastron. It follows that the larger components of these systems must be more massive than the sun, and the invisible companions of the order of one tenth the mass of their primaries—as Campbell has anticipated.

The great brightness of all these variable stars seems a very serious objection to any theory which represents them as stars nearing extinction, but

unfortunately, does not itself suggest any theory of their nature.

*The Jupiter Perturbations of the Group of Small Planets,  $\mu = 2/5$ : D. T. WILSON.*

Tables have been constructed by the Hansen-Bohlin method for the computation of the perturbations of Jupiter on the group of small planets whose mean daily motions are in the neighborhood of 750". The perturbations of Pandora 55, of Bellona 28 and of Johanna 127 have been computed and the results compared with those of the same planets computed by Hansen's method by Messrs. Möller, Bohlin and Olsson.

*Correcting and Testing Micrometer Screws: WM. GAERTNER.*

Read by title.

*The Temperature assigned by Langley to the Moon: FRANK W. VERY.*

Langley's opinions in regard to the temperature of the lunar surface in sunshine varied widely at different times, but in the main he favored a low temperature.

The foundation of this opinion is examined and is shown to be invalid. Incidentally, statements by other investigators, which are based to some extent on Langley's opinion, are discussed.

The paper will be published in SCIENCE.

At the end of the last session a resolution was adopted expressing the thanks of the society to the authorities of Case School and other friends in Cleveland for the hospitality and privileges extended to the members of the Society.

NEW SERIES  
Vol. XXXVII. No. 957

FRIDAY, MAY 2, 1913

SINGLE COPIES, 15 Cts.  
ANNUAL SUBSCRIPTION, \$5.00

## Daugherty's Economic Zoology

This work is issued, for convenience, in two parts. Part I is a *Field and Laboratory Guide*, interleaved for notes. Part II is the textbook part or the *Principles*. Not only does this work give the salient facts of structural zoology and the development of the various branches of animals, but also the natural history—the *life and habits*.

**J. Remsen Bishop, Ph.D.**, Eastern High School, Detroit: "The illustrations alone prove the book superior to any other on the subject. The text seems to cover the ground very thoroughly."

*Economic Zoology.* By L. S. Daugherty, M.S., Ph.D., Professor of Zoology, State Normal School, Kirksville, Mo.; and M. C. Daugherty. Part I—*Field and Laboratory Guide*. 12mo of 275 pages, interleaved. Cloth, \$1.25 net. Part II—*Principles*. 12mo of 406 pages, illustrated. Cloth, \$2.00 net.

## Drew's Invertebrate Zoology

Professor Drew's work gives the student a working knowledge of comparative anatomy and leads him to an appreciation of the adaptation of the animals to their environments. The type method is followed.

**Prof. John M. Tyler**, Amherst College: "It covers the ground well, is clear and very compact. The table of definitions is excellent."

*Invertebrate Zoology.* By Gilman A. Drew, Ph.D., Professor of Biology, University of Maine. 12mo of 201 pages. Cloth, \$1.25 net.

## McFarland's Biology

This work has chapters on the origin of life and its manifestations, the cell and cell division, reproduction, ontogenesis, conformity to type, divergence, structural and blood relationship, parasitism, mutilation and regeneration, grafting, senescence, etc.

**Prof. W. R. McConnell**, Pennsylvania State College: "It has some admirable features, the most valuable of which is the careful resume of the subjects of heredity and evolution."

*Biology: General and Medical.* By Joseph McFarland, M.D., Professor of Pathology and Bacteriology, Medico-Chirurgical College, Philadelphia. 12mo of 440 pages, illustrated. Cloth, \$1.75 net.

## Stiles' Nutritional Physiology

Dr. Stiles takes up each organ, each secretion concerned with the process of digestion, discussing the part each plays in the physiology of nutrition—in the transformation of energy. A valuable feature is Dr. Stiles' happy use of homely similes.

**Prof. Colin C. Stewart**, Dartmouth College: "It is remarkable for the fineness of its diction and for its clear presentation of the subject."

*Nutritional Physiology.* By Percy G. Stiles, Assistant Professor of Physiology in Simmons College; Boston. 12mo of 271 pages, illustrated. Cloth, \$1.25 net.

W. B. SAUNDERS COMPANY

West Washington Square, Phila.

Published March, 1913. Pages x+484. Price, \$3.00 net

## University Control

By J. McKEEN CATTELL, Professor of Psychology in Columbia University

Together with a series of Two Hundred and Ninety-nine Unsigned Letters by Leading Men of Science holding Academic Positions and Articles by JOSEPH JASTROW, GEORGE T. LADD, JOHN J. STEVENSON, J. E. CREIGHTON, J. McKEEN CATTELL, GEORGE M. STRATTON, STEWART PATON, JOHN JAY CHAPMAN, JAMES P. MUNROE and JACOB GOULD SCHURMAN.

A great variety of questions concerning general university administration are dealt with in an original and helpful way.—*Nature*.

These quotations and examples are taken from Professor Cattell's informed and thorough discussion of the subject of university control, a subject upon which he has had much to say of late, finding occasion for caustic criticism of existing American conditions, and standing as the champion of an academic democracy and a teaching profession upon which a man may enter without forfeiting his self-respect.—*The Dial*.

Sentences and paragraphs that betoken the expert, highly-trained mind, the suggestions that come to refresh and tell us that a new day is about to dawn in educational writing.—*The Boston Evening Transcript*.

## SCIENCE AND EDUCATION

*A series of volumes for the promotion of scientific research and educational progress*

VOLUME I. *The Foundations of Science.* By H. POINCARÉ. Containing the authorized English translation by GEORGE BRUCE HALSTED of "Science and Hypothesis," "The Value of Science," and "Science and Methods."—*In Press*.

VOLUME II. *Medical Research and Education.* By RICHARD M. PEARCE, WILLIAM H. WELCH, W. H. HOWELL, FRANKLIN P. MALL, LEWELLYS F. BARKER, CHARLES S. MINOT, W. B. CANNON, W. T. COUNCILMAN, THEOBALD SMITH, S. J. MELTZER, JAMES EWING, W. W. KEEN, HENRY H. DONALDSON, CHRISTIAN A. HERTER, and HENRY P. BOWDITCH. *In Press*.

## THE COLLEGE PRESIDENCY

THE only qualification I have for discussing the college presidency is the extraordinary opportunity I have had for studying colleges at first hand. During the past three years I have visited one hundred and five of the institutions listed in the reports of the United States Commissioner of Education as universities and colleges. These one hundred and five institutions are in twenty-nine states.

The main object of my travels has been to learn what I could about higher education in the United States; and, for various reasons, I have learned much from the inside. I have been a guest of the household. Trustees and faculty, students and citizens, have appeared glad to find a member of their profession, from afar, upon whom they could unburden themselves with fair assurance that the confidence would not be violated. I trust that I can be sufficiently concrete in discussing the college presidency without proving myself an ungracious guest.

Of the one hundred and five colleges and universities that I have visited I have become sufficiently acquainted with possibly fifty-one to form judgments concerning the success of their presidents in meeting the expectations of those whom they served. In other words, I believe that, in fifty-one cases, I have uncovered the sentiment of teachers, students and graduates with respect to their presidents. In the other cases, I have not collected adequate evidence for a valid generalization; either the testimony has been meager, or, though abundant, it has not pointed unmistakably in one direction. In these cases the presi-

dents may or may not be satisfactory to their constituents. I do not know.

Of the fifty-one presidents, thirty-four appear to be unsatisfactory. I mean that a majority of the faculty, students and alumni of thirty-four institutions *appear* to be in favor of a new president. In other words, if my observations are correct, two college presidents out of three are regarded as failures. If there is any error here due to the selection of institutions, it tends to make the proportion of failures too small, inasmuch as I purposely sought instances of satisfactory administration, colleges generally regarded as successful, those most likely to be attractive to men of power. Furthermore, had I taken a period of years, instead of one year, the proportion of failures would have been larger, since only those presidents who have survived are included in these figures. For example, one of the institutions, now in the successful list, had disposed of three unsatisfactory presidents in ten years.

On the other hand, it may be true that a man engaged in finding teachers for a new college was more likely to meet the disgruntled than the contented members of faculties. And it goes without saying that my judgment may have been false, even where the sentiment appeared to be almost unanimously in favor of or opposed to the retention of the president. It was not always so easy to get at the facts as it was in one college where the entire faculty, with one exception, had just petitioned the trustees for a new president. I dare say that certain complaining faculties, if sobered with the responsibility of an actual vote, would bear with their presidential troubles rather than fly to ills they knew not of.

Nevertheless, after these attempts to safeguard my conclusion against error, I

am satisfied that a majority of college and university presidents in the United States have failed, on the whole, to perform, to the satisfaction of those most intimately concerned, the various duties now assigned to that office. If I were to class as failures those who had proved unequal to one or more of the obligations usually attached to the office, there would remain in the successful group scarcely a score. And who knows what reduction would appear in this small list if it were submitted for approval to a representative group of university leaders—let us say, to the American Association for the Advancement of Science?

With the chances of entire success in the college presidency two to one against the incumbent, it is a bold college professor who *seeks* the office. Possibly he has no adequate conception of the obligations involved.

What are those obligations? What do we expect of the American college president? From my observations, I am inclined to sum it up by saying that he must be all things to all men at all times and under all circumstances.

First of all he must be a scholar; he must have achieved distinction in a particular field, and he must continue to advance knowledge in that field. Otherwise he is not regarded as a respectable head for a so-called institution of higher learning, and comes to be regarded with contempt by certain scholars of the faculty. This means that he must have spent most of his life, before election to the presidency, in preparation for something other than the presidency; and, after election, he must spend much of his time, no matter how urgent his other duties may be, in work that has little to do with administration.

A second obligation is that of teaching.

It is urged with reason that the college president should be a good teacher and should continue to teach, in order that he may keep in close touch with the students and with the teaching problems of his faculty. The American college has been widely condemned in recent years because many of its classes have been entrusted to young persons who did not know how to teach and to scholars who did not care to teach. It is said that the college has neglected its function of teaching partly because the president and the classroom have been divorced.

It is said, with equal reason, that the college president should supervise the teaching. Expert supervision is regarded as absolutely necessary in every other branch of education, even though the means for training teachers, and the professional requirements of teachers, for all schools below the college are so much better than formerly. Yet the group which has the least preparation for teaching is the very group that teaches with the least supervision. At many a college, the president never appears in the classroom. If he is to be held responsible for the college as a teaching institution, and for the retention and promotion of men partly because of teaching ability, it is reasonable to expect him to supervise the teaching, until that duty is definitely assigned to another person. Supervision is, therefore, regarded by many persons as a third among the president's obligations.

A fourth duty of the president is business management. The increasing complexity of college affairs; the larger and more elaborate budgets; the development of new departments; the promotion of profitable relations with other institutions; the growth of the material equipment—buildings, laboratories, gardens, farms, museums, hospitals, dormitories, dining-

halls, experiment stations, libraries, playgrounds;—all thrust upon the college executive obligations similar to those that exact the entire time and strength of the head of a commercial enterprise. If the business organization of the institution is to bring about and maintain the maximum economy and achievement, it demands the constant care of a man whose services in the open market are rewarded with several times the usual college president's salary. I know a man who was recently offered the presidency of a university at a salary of ten thousand dollars. He chose to retain his professorship at less than half that salary. He told me that if he were to give up his opportunities to study and write and teach in favor of a business career, he would accept—not the university presidency—but a previous offer to manage a commercial house at a much larger salary. As a matter of fact college presidents do delegate business matters to other officers; but, in nearly all instances, the ultimate responsibility, apart from the investment of funds, rests upon the president of a college, as it does upon the president of a railroad, or a bank, or a department store.

A fifth duty of the president—the raising of funds—is akin to the last; it is business, but a highly specialized form of business. It has no counterpart among the obligations that fall upon the head of an ordinary commercial establishment. No matter how well-endowed the institution may be, or how liberally supported by public taxation, the president is expected to increase its resources. Each alumnus applauds the effort—until the president reaches *him*. I have heard many of the faculty and graduates of a certain college flatly condemn their president—certainly among the ablest dozen college presidents in America—because they thought he had failed in this one part of his job, though

they admitted his notable success in every other part. In a few places, as at Oberlin, the increasing of the endowment has been made the business of a special officer; but in nearly all institutions the success of the president is measured to a considerable extent by his results in this specialized form of begging. If the institution is dependent on the periodic whims of legislatures, certain qualities are needed—those that make the expert lobbyist. If the institution is private, other qualities are needed. In either case, the man who is equal to the task could receive large rewards for his work in the domain of commerce—and be judged by his success in this one thing instead of a dozen.

But this is not all. The social obligations of the office—a sixth group of duties—are real and heavy, and they are becoming more exacting every year. Several men who a decade or two ago were regarded as admirable for the presidency of a certain university are now considered impossible because they *or their wives* are not socially notable, or because they have insufficient income for the extensive entertaining that now seems inseparable from the position. A man might be elected president of a railroad because of what he himself could do. Not so with the college president. He *and* his wife are elected. Some men disqualify themselves early in life by falling in love with a woman who could never become the social servant of a university.

It is part of the president's social duty to keep in close touch with the students, in order that he may contribute to their social education, and incidentally find out what is going on in the institution, to the end that he may wisely administer student affairs. The social duties also pertain to relations with alumni, for the president must seek opportunities of educating them, in order

that they may help instead of hinder the progress of the university. The president is regarded by visitors from abroad as a social figure head, a public host, on duty the year round. But most important of all in the eyes of the trustees are the social obligations resplendent with the possibilities of influencing benefactors. There is no club or committee, no dinner or dance, no tea or reception, no convention or fair, no rally or round-up without its possibilities. The president and his wife could easily spend all their time and energy, and many times their salary, in social functions at their home and abroad, related in definite and promising ways to the satisfaction of the growing needs of the institution. Whatever one may think of all this as a concern of higher education, the social obligations of the president and his wife are real and heavy, and to a large extent, unavoidable.

In the seventh place, the president is called upon for every known form of public speaking. The idea prevails that he should be ready to speak at any time, on any subject, to any audience, anywhere; and some men apparently try to live up to the idea. He is expected to deliver eulogies over the bodies of prominent citizens and to make men merry with his after-dinner speeches; he is asked to address the chamber of commerce and the Browning Club; he is urged to harangue political mass meetings and to read poems at the dedication of Carnegie libraries; there are traditional obligations to preach sermons and conduct funerals; there are always the demands of teachers' conventions and alumni meetings, of women's clubs and legislative hearings, and others without number. What the next one may be he can not predict. Much of the proposed speaking he can avoid, but there is much that goes with the office. A man who could not speak in public might attain eminence as a physician, engineer, mer-

chant, architect, banker, scientist or playwright; a college president is sure to fail in much that is expected of him unless he is a public speaker of considerable power.

One of the essential qualifications of the college president I have left until the last; it is possibly the rarest and most important of all. He must get on with men and women, and somehow keep them working harmoniously and enthusiastically for the really important things in the life of the institution. He must needs be a spiritual force.

This power of leadership is made up of many elements. The first and last is patience. Another is a catholic interest and sympathy that enables him quickly to get the viewpoint of other men. Another is primary devotion to things bigger than himself, for a self-seeking man can not retain leadership in a college community. Another is a sense of his own limitations, for conceit repels. Conceit, however, is not likely to survive long after one attempts all that is expected of him as a college president.

Consider this necessity for getting on with men, retaining their confidence and loyalty, yet yielding no principle. He must command the support of trustees for policies they do not understand; he must deal justly with both factions of a faculty to the probable satisfaction of neither; he must keep the faculty happy without the desired salaries, staff and appropriations; he must deny the students what seem to them the chief desires of their hearts; he must send boys home and tell their parents that they are not equal to other men's children; he must defer the ambitious projects of citizens, in devotion to ideals the city can not share; he must use the alumni in making changes which the alumni naturally oppose; he must bring benefactors close to the college, while denying them the privi-

lege of controlling it; he must attack tradition among worshippers of tradition; he must face opposition whether he performs or fails to perform any particular act; he must spend more time than he has, in explaining his conduct, or be condemned for not explaining. All these, and many more, are among the obligations of the presidency.

The question what *should* be expected of a college president I have not ventured to discuss. I have confined myself to conditions as I have found them in one hundred of our better institutions. I now venture to suggest that the trouble is not chiefly with the men, but with the post. Trustees do not, as a rule, select the least competent persons available; but they offer to men who have proved competent within a reasonable scope an almost impossible array of tasks. There are five hundred college presidencies, and not enough men to go around, as the office has evolved in the United States. There is something in the remark that a college president is "neither fish, nor flesh, nor good red herring." And there is something more than humor in the charge that a college president is, "*ex-officio*, a liar and a coward." A person in public office, attempting the impossible, is liable to every kind of criticism.

I venture the further suggestion that the remedy is not to curb the power of the president, while continuing to expect too much; it will not help matters to encumber executive action with complications and delays, while leaving upon the office more duties than a man could meet even with the power of a despot. The college president is already regarded as a poor risk by life insurance companies.

It may be best to assign certain of the functions enumerated above to other officers. The duty of spiritual leadership, historically the most important of the functions of the college president in America,

has now been delegated in many places to a chaplain or a board of preachers. But the change has not been applauded always by those who believe in moral and religious education. The increase of endowment and equipment may be assigned to a special officer, but the president is, *ex-officio*, more likely to influence prospective benefactors. So, also, with social obligations, they attach to the office; they can not be transferred to another person, by executive action or by vote, like the advertising department of a soap factory. The president can easily turn over to others all the privileges of the scholar, the supervisor and the teacher; but the fact that he has done so is one of the present charges against him. Furthermore, he is loath to resign these privileges, if he has any capacity for intellectual leadership. Finally, the president might be relieved of business management—that branch of affairs which has always been most foreign to the dominant interests of great scholars and great teachers. But, as a matter of fact, I have found the most confusion and the unhappiest faculties in those institutions, of all that I have visited, where the authority in business matters has been vested in some person or persons other than the president. Nobody can possibly make a budget satisfactory to all concerned; but the one most likely to take successful leadership in budget-making is the one most intimately and sympathetically in touch with every aspect of the life of the university. That person, under present conditions, is the president. His other duties are so intricately involved with business affairs, that it seems unreasonable to withhold control in this domain while holding him responsible in others.

In short, the principle of centralization of responsibility and adequate authority, which is well established in all public school

affairs, must be reckoned with in all new plans for university control. Something should be done by way of reorganization or definition, to the end that a college may have more than one chance in three of obtaining a successful president. But whatever is done should be based on this principle of centralization of responsibility with adequate authority, and on the scope and the difficulties of the president's obligations.

The discussion of faculty control carried on in SCIENCE, and elsewhere, is much to the point. It should lead presidents to clearer ideas of their short-comings and professors to a more sympathetic understanding of the causes. It should lead to greater faculty control through officers elected by the faculty for short terms, and to faculty representation at stated meetings of the trustees. It should lead to a fixed plan for salaries in each institution, that would go a long way toward reducing the proportion of failures among presidents. Finally, I believe this whole discussion should bring us to some consideration of the fact that preparation for the office of president, in spite of the excessive demands upon the office, is left largely to chance. So far as I know, there is not even a course in higher education given in any college or university in America. Nor is there such an opportunity as a Kahn traveling fellowship might provide for prospective presidents. When we consider the administration of higher education of sufficient importance, we shall make provision for trained leadership. Meantime, let us all be charitable,—trustees, presidents, professors, graduates, students; our faults are many, and which of us is without them?

WILLIAM T. FOSTER

REED COLLEGE,  
PORTLAND, ORE.

*THE IMPERIAL BUREAU OF ENTOMOLOGY*

As the question of international effort and cooperation in the matter of controlling and preventing the spread of insects which in various ways affect human activity is occupying the attention, not only of entomologists, sanitarians and workers directly occupied in studying these many-sided problems, but also of statesmen and administrators, the formation in connection with the British Imperial service of an Imperial Bureau of Entomology at the beginning of the present year will undoubtedly interest all concerned in these problems, by whom its progress and work will be watched.

This organization is not a sudden development but a gradual outgrowth of efforts along similar lines which began in the spring of 1909. In March of that year a meeting was called by the secretary of state for the colonies at the colonial office in London, in which the present writer had the honor to take part, to discuss the formation of an entomological research committee for the purpose of furthering entomological research in the British possessions in tropical and subtropical Africa. The chief insects which it was considered desirable to study were those associated with the transmission of disease. In 1909 an entomological research committee of the colonial office was appointed by Lord Crewe, then secretary of state for the colonies, and it consisted of the chief experts in entomology and tropical medicine in Great Britain and Ireland, with Lord Cromer as chairman. Its work fell under three divisions, namely, the carrying on of investigations and entomological surveys in tropical Africa, for the purpose of which two traveling entomologists were employed; the determination of entomological material, and the publication of the work so accomplished, for which purpose the *Bulletin of Entomological Research*, a quarterly journal, was started. Through the generosity of Mr. Andrew Carnegie, the committee was able also to undertake the training of a number of entomologists for service in the dominions and colonies.

On account of the valuable service which

was being rendered by the committee to the African crown colonies and protectorates, suggestions were made for the enlargement of the scope of the work of the committee. Accordingly, in June, 1911, advantage was taken of the presence in England of the prime ministers of the self-governing dominions and a conference was called by the secretary of state for the colonies to consider the desirability of further extending the work already begun by securing the cooperation and financial support of the self-governing dominions and colonies. By these means mutual assistance could be rendered by the various countries within the British Empire through the medium of a central bureau which would be engaged in the collection and interchange of information in regard to noxious insects. It was unanimously agreed that the establishment of such a central bureau was desirable, as it was realized what valuable assistance it could render in the way of disseminating information and rendering assistance in other ways. Accordingly, a tentative scheme was submitted to the governments of the various self-governing dominions and colonies for their consideration.

After due consideration and consultation a further conference was held at the colonial office in August, 1912, to which the government entomologists of the self-governing dominions and colonies and others similarly interested were invited, to discuss and work out a scheme for imperial cooperation in preventing the spread and furthering the investigation of noxious insects. At this conference the whole subject was thoroughly discussed and a proposal was evolved for the establishment of an imperial bureau of entomology to be financially supported by the various dominions and colonies and the British government.

It was proposed that the functions of the Imperial Bureau of Entomology should be as follows:

1. A general survey of the noxious insects of the world and the collection and coordination of information relating thereto, so that any British country may learn by enquiry

what insect pests it is likely to import from other countries and the best methods of preventing their introduction and spread.

2. The authoritative identification of insects of economic importance submitted by the officials of the Departments of Agriculture of Public Health throughout the empire.

3. The publication of a monthly journal giving concise and useful summaries of all the current literature which has a practical bearing on the investigation and control of noxious insects.

The scheme was accepted by the various self-governing dominions and colonies which were invited to cooperate, and the crown-colonies and British protectorates will also participate in the advantages of the Imperial Bureau of Entomology which has now been established. The former entomological research committee has become the honorary committee of management with the eminent administrator, the Earl of Cromer, as president and the scientific secretary of the committee, Mr. Guy A. K. Marshall, has been made director of the bureau and editor of the journal. The government entomologists of the dominions are *ex-officio* members of the committee of management.

The publication of the bureau's journal, which is entitled *The Review of Applied Entomology*, was commenced in January. It is being published in two parts: Series A, Agricultural, and Series B, Medical and Veterinary. As the organization and library of the bureau becomes perfected the value of this journal to entomological workers can not be overestimated, when it is remembered that there are no less than 1,700 periodicals, scientific, agricultural and medical, which may contain articles dealing with entomology, but a small proportion of which widely scattered entomologists have the opportunity of seeing or the time to consult.

An idea of one aspect of the three years work of the original entomological research committee will be gathered from the fact that the collections received from collectors in tropical Africa and other parts of the world during that time amounted to about 190,000 in-

sects, of which no less than 56,000 were actual or potential disease carriers. The value of this function of the Bureau to entomologists situated in portions of the empire where there are no collections and little literature to aid in identification work will be realized by their more fortunate fellow-workers.

It has been stated in the press that the Imperial Bureau of Entomology will serve the needs of the British Empire in a manner similar to that in which the United States Bureau of Entomology serves those of the United States. This statement, however, is not correct. Its primary function will be that of an intelligence bureau, collecting information for the use of the British countries supporting it and assisting entomologists and other officials in those countries in the identification of their material. By the methods which have been mentioned, and by the publication of *The Review of Applied Entomology*, and of *The Bulletin of Entomological Research*, it will furnish a means of assistance and of coordination of effort in the war against noxious insects which will undoubtedly soon make its services invaluable in the further development of the countries of the British Empire. International as the scope of its inquiries are, the work of the Bureau can not but prove to be one of the most potent factors in enabling us to develop the agricultural and other resources of the empire and our fellow-workers in non-British countries can avail themselves, through its journal, of some of the fruits of the Bureau's work.

C. GORDON HEWITT,  
*Dominion Entomologist*

OTTAWA, CANADA,  
March, 1913

---

THE COMMITTEE ON THE PACIFIC COAST  
MEETING OF THE AMERICAN  
ASSOCIATION

THE committee on the Pacific Coast meeting of the American Association held its first meeting at the University of California on April 12, 1913, with Director Campbell in the chair. About twenty members were pres-

ent. The following resolution was unanimously adopted:

This committee, on behalf of the western members of the American Association for the Advancement of Science, expresses its gratification at the proposal to hold a meeting on the Pacific Coast during the summer of the year 1915, and hereby extends a cordial invitation to the association and to all its affiliated societies to meet in San Francisco at the time of the Panama Exposition.

Sub-committees and their chairmen were appointed as follows: Time and place of meeting, A. C. Lawson; transportation, H. S. Ryan; hotels and accommodations, A. L. Kroeber; program, G. E. Hale; excursions, A. G. McAdie; reception and entertainment of visiting ladies, Agnes Claypole Moody; membership, Vernon L. Kellogg; publicity, J. C. Merriam; finance, D. T. MacDougal; executive committee, W. W. Campbell. An honorary local committee of one hundred will also be appointed.

The question of the organization of the Pacific Coast members into a geographical division with power to hold meetings and present scientific programs was discussed at length. A motion that it be the sense of the committee that such a division should be established was unanimously carried; but it was the general feeling that the success of such a step would depend upon the attitude of the Pacific Association of Scientific Societies. It is to be hoped that this association will merge itself into the Pacific Coast Division of the American Association and its constituent societies become affiliated with the latter. The executive committee was asked to consider the whole matter and to endeavor to secure the cooperation of the various scientific societies on the Pacific Slope.

The affiliation of these societies and an active campaign for membership would undoubtedly greatly increase the membership of the association on the Pacific Coast. This, together with the attractive features of the exposition and the varied natural beauties of the Pacific slope, should cause a very large attendance at the meeting in 1915.

E. P. LEWIS,  
*Secretary*

MINUTES OF THE COUNCIL OF THE  
AMERICAN ASSOCIATION FOR THE  
ADVANCEMENT OF SCIENCE

The council of the association met at the Cosmos Club, Washington, on Tuesday, April 22, 1913, at 5 P.M. Those present were: Messrs. Wilson, Alsberg, Bessey, Boas, Cattell, Campbell, Diller, Humphreys, Kober, MacBride, MacDougal, Nichols, Pickering, Woodward and Howard.

The permanent secretary read nominations made by the sectional committee of Section K for Dr. Theodore Hough, as vice-president and chairman, and Dr. John R. Murlin, as secretary. On motion, these were elected.

On motion, Mr. Seymour C. Loomis was made a fellow of the association.

Mr. Cattell submitted the report of the committee on policy, and, on motion, the following resolutions recommended by the committee were adopted:

*Resolved*, That the Pacific Coast committee be authorized to secure an associate secretary for the Pacific Coast at a salary of one hundred dollars a month, this officer to devote at least one half of his working time on the work of the Pacific Coast committee in the effort to advance the interests and increase the membership of the association under the direction of the Pacific Coast committee, and, further, that an appropriation of six hundred dollars, or so much thereof as may be necessary, be made for paying the office and traveling expenses of such secretary.

*Resolved*, That a committee consisting of Messrs. J. A. Holmes, W. J. Humphreys, H. M. Smith and the permanent secretary, be authorized in the early autumn to select and appoint a temporary associate secretary for the south at a salary of two hundred dollars a month, for not more than four months, with two hundred dollars in addition for traveling and office expenses, whose duties shall be to advance the interests and increase the membership of the association in the south, with an especial effort to increase the interest in, and the attendance at, the Atlanta meeting.

On motion, the recommendation that Dr. Carl L. Alsberg be elected vice-president and chairman of Section C was adopted.

On motion, Dr. Walter B. Pillsbury was made a fellow of the association, followed by the adoption of a motion that he be elected vice-president and chairman of Section H.

On motion, Mr. Judson G. Wall was made a fellow of the association, followed by the adoption of a motion that he be elected vice-president and chairman of Section I.

The following resolutions recommended by the committee on policy were adopted:

*Resolved*, That the Pacific Coast committee be authorized, in the absence of constitutional authority, to designate its meetings at which scientific programs are presented as "Meetings of the Pacific Coast Division of the American Association for the Advancement of Science."

*Resolved*, That the Pacific Coast committee be placed in charge of all arrangements, including program, for the proposed Pacific Coast meetings in 1915 in cooperation with the several sectional secretaries and in consultation with the permanent secretary.

The following preamble and resolution recommended by the committee on policy was adopted:

WHEREAS, It is eminently desirable that scientific men especially skilled in their departments be appointed as heads of the scientific bureaus of the government, therefore,

*Resolved*, That a committee of three be appointed to communicate to the President of the United States that it is the opinion of the council of the American Association for the Advancement of Science that a scientific man skilled in meteorology should be selected as the Chief of the Weather Bureau.

The following resolution recommended by the committee on policy was adopted:

*Resolved*, That the president be authorized, with the advice of the committee on policy, to appoint a Committee of One Hundred on Scientific Research under the government, in the universities and in other institutions.

On motion, it was

*Resolved*, That the council allow the sectional committee of Section C to nominate and elect the new secretary of that section.

On motion, it was

*Resolved*, That the council delegate full powers to the committee on policy with respect to all arrangements concerning the organization of the Pacific Coast Division of the association, including all matters relating to the affiliation of the indi-

vidual societies composing the present Pacific Association of Scientific Societies.

At 6.10 P.M., the council adjourned.

L. O. HOWARD,  
*Permanent Secretary*

#### THE ANNIVERSARY MEETING OF THE NATIONAL ACADEMY OF SCIENCES

THE National Academy of Sciences celebrated the semi-centennial anniversary of its foundation on April 22, 23 and 24, exactly fifty years after its first meeting. It was a most successful meeting with the largest attendance of members in the history of the academy. There was no program of technical papers, but in its place a series of addresses. Dr. Ira Remsen, the president of the academy, at the first session read an address on the history of the academy, and then introduced President Arthur T. Hadley, of Yale University, who spoke on "The Relation of Science to Higher Education in America." He was followed by Dr. Arthur Schuster, secretary of the Royal Society of London, who spoke on "International Cooperation in Research." At the afternoon session Dr. George E. Hale, director of the Mt. Wilson Solar Observatory, gave an address on "The Earth and Sun as Magnets." On the morning of the following day, Dr. J. C. Kapteyn, director of the Astronomical laboratory of the University of Groningen, gave an address on "The Structure of the Universe." Dr. Theodor H. Boveri, of the University of Würzburg, was to have spoken on "The Material Basis of Heredity," but was unable to be present owing to ill health.

The program left ample time for social events, which were admirably arranged. Luncheons were provided each day and there were evening receptions at the National Museum and the Carnegie Institution. The afternoon of April 24 was devoted to an excursion to Mt. Vernon on the U. S. S. *Mayflower*. On the afternoon of April 23, there was a reception at the White House, when the President of the United States conferred medals, and afterwards, with Mrs. Wilson,

received and entertained the members of the academy and their guests. The Watson medal for astronomical research was presented to Dr. J. C. Kapteyn, the Draper medal for astrophysical research to the French Ambassador for M. Henri Deslandres, the Agassiz medal for oceanographical research to the Norwegian minister for Dr. Johan Hjört, and the Comstock prize of the value of \$1,500 for research in radiant energy, to Professor R. A. Millikan, of the University of Chicago. At the dinner on the evening of April 24, Dr. R. S. Woodward acted as toastmaster and speeches were made by the vice-president of the United States, the British Ambassador, Dr. S. Wier Mitchell, Dr. W. W. Keen, president of the American Philosophical Society, and Senator Burton.

At the business meeting of the academy the following new members were elected: Henry Andrews Bumstead, professor of physics, Yale University; L. E. Dickson, professor of mathematics, University of Chicago; Ross G. Harrison, professor of comparative anatomy, Yale University; Gilbert Newton Lewis, professor of physical chemistry, University of California; Lafayette B. Mendel, professor of physiological chemistry, Yale University; George H. Parker, professor of zoology, Harvard University; L. V. Pirsson, professor of geology, Yale University; Edward B. Rosa, chief physicist, Bureau of Standards; Erwin F. Smith, pathologist in charge, Bureau of Plant Industry, U. S. Department of Agriculture; A. O. Leuschner, professor of astronomy, University of California.

The officers elected for a term of six years were:

*President*—Dr. W. H. Welch, professor of pathology, The Johns Hopkins University.

*Vice-president*—Dr. Charles D. Walcott, secretary of the Smithsonian Institution.

*Home Secretary*—Dr. A. L. Day, director of the Geophysical Laboratory of the Carnegie Institution.

#### SCIENTIFIC NOTES AND NEWS

SIR WILLIAM OSLER, regius professor of medicine, gave, last week, the Silliman lec-

tures at Yale University. The subject of the course was "The Evolution of Modern Medicine."

THE Walker grand honorary prize, which is awarded by the Boston Society of Natural History once in five years, was this year voted to Mr. Robert Ridgway, of the United States National Museum, in recognition of his investigations in ornithology, and particularly for his work on the "Birds of North and Middle America." This prize, the amount of which is one thousand dollars, was founded by the late William Johnson Walker, a benefactor of the society, and is given in recognition of important investigation in natural history, published and made known in the United States of America.

PRESIDENT RICHARD C. MACLAURIN, of the Massachusetts Institute of Technology, has taken out the first papers for citizenship in the United States. His statement shows that he was born in Scotland, forty-six years ago, and that his last foreign place of residence was New Zealand.

DR. R. S. BREED, for several years professor of biology at Alleghany College, has been selected as bacteriologist of the New York Agricultural Experiment Station, Geneva, N. Y. Dr. Breed succeeds Dr. H. A. Harding who becomes head of the dairy department of the University of Illinois. Dr. Breed is a graduate of Amherst and of Harvard, having a Ph.D. from the latter institution. He will assume the duties of this position about August first.

DR. MAURICE C. TANQUARY, instructor in zoology in the Kansas State Agricultural College, has been granted a three years' leave of absence in order that he may accompany the American Museum of Natural History Crocker Land Expedition.

DR. A. HRDLICKA, of the U. S. National Museum, has returned from his expedition to Peru. He has secured important collections in physical anthropology and pre-Columbian pathology.

DR. FRANK K. CAMERON, of the U. S. Bureau of Soils, visited the Pacific coast during April in the interests of the fertilizer investigation. In Seattle he delivered before the local society of Sigma Xi an address on "A Dynamic View of Soil Fertility." He was accompanied on the trip by Dr. J. W. Turrentine, who will remain on the coast during the summer, investigating fertilizer resources.

PROFESSOR WILLIAM HERBERT HOBBS, who has been abroad on leave of absence since June, 1912, has now returned to the University of Michigan. In the summer of 1912 Dr. Hobbs carried out tectonic and glacial studies in the Swiss and French Alps, and in the following winter visited the deserts of Egypt and the Soudan.

DR. N. L. BRITTON and Dr. J. N. Rose, who left New York City on January 25, for the purpose of making a special study of the *Cactaceæ* of the West Indies have returned. Although they went especially in the interest of the cactus investigation of the Carnegie Institution of Washington, yet a general botanical survey was made, and they have brought back a very large collection of living plants and about 13,000 herbarium specimens. They went first to St. Thomas, where the party was divided. Dr. and Mrs. Britton, Dr. J. A. Shafer and Miss Delia W. Marble, explored the Virgin Islands, Porto Rico and Curaçao, while Dr. Rose, accompanied by Wm. R. Fitch and Paul G. Russell, visited St. Croix, St. Kitts and Antigua, and, after returning to St. Thomas, made extensive collections in Santo Domingo along the southern side and eastern end of the island.

HENRY H. NORRIS, professor of electrical engineering in Cornell University and secretary of the Society for the Promotion of Engineering Education, is devoting a leave of absence to a special investigation for the McGraw-Hill Book Company of engineering books in all fields. He will cover both college text-books and general reference books. His work is practically a scientific investigation of these texts. On the basis of this in-

vestigation and the suggestions which Professor Norris will collect, a broad series of new books will be planned and undertaken for all fields of engineering, with a view to a new and more useful technical literature.

THE following lectures have been arranged by the department of chemistry of the College of the City of New York:

April 11—Professor Alexander Smith, professor of chemistry and director of the laboratory, Columbia University: "Forms of Sulphur and their Relations."

April 25—Dr. Charles F. McKenna, past president Institute of Chemical Engineers: "Chemical Engineering, Present and Future."

May 9—Mr. A. D. Little, president American Chemical Society: "Manufacture of Wood Pulp and Paper."

May 23—Dr. M. W. Franklin, General Electric Co.: "Ozone."

GEORGE C. WHIPPLE, professor of sanitary engineering at Harvard University, is giving a course of lectures on "Applications of Water Analysis" at the Polytechnic Institute of Brooklyn.

DR. THEOBOLD SMITH, of Harvard University, delivered an address to the Pathological Society of Philadelphia, April 24, on "An Attempt to Interpret Present-day Uses of Vaccines."

ON April 7 Dr. D. T. MacDougal, of the Carnegie Desert Laboratory, lectured before the Southern California Academy of Sciences in Los Angeles, on "Some Physical and Biological Problems of American Deserts."

THE life and services of Dr. John Shaw Billings, late director of the New York Public Library, who died on March 11, were commemorated, before a notable gathering in the Stuart gallery of the Public Library on April 26. Mr. John L. Cadwalader, president of the New York Public Library, presided, and first introduced Dr. S. Weir Mitchell, as one of Dr. Billings's oldest and closest friends, who told of the arduous services rendered by him in his early years in the civil war. Sir William Osler described his great contribution to bibliography. Dr. William H. Welch paid

tribute in behalf of the trustees of Johns Hopkins Medical School and the medical profession to the services of Dr. Billings as a hospital organizer. Mr. Andrew Carnegie spoke of his associations with him in library work and in the organization and conduct of the Carnegie Institution of Washington. Mr. R. R. Bowker presented the tribute and homage of the library profession to the memory of Dr. Billings and his work.

At the meeting of the Johns Hopkins Hospital Historical Club on April 14, Dr. Fielding H. Garrison presented to the medical school a portrait of the late Dr. Robert Fletcher, of the Surgeon-General's Library, Washington, D. C.

DR. ANDREW SLOAN DRAPER, New York state commissioner of education, and former president of the University of Illinois, died at Albany on April 27, aged sixty-four years.

ON April 10 the Brooklyn Botanic Garden began the publication of four-page *Leaflets*. The purpose of the *Leaflets* is twofold: "first, to give announcements concerning flowering, and other plant activities to be seen in the garden at the time the leaflet is issued; second, to give popular, elementary information about plant life, primarily for teachers, or for others who may wish to learn something about plants besides merely their names." Some of the numbers will aim to give, in simple, non-technical language, the subject-matter for a nature study lesson, which may be conducted by the teacher, in the garden or elsewhere. The *Leaflets*, which for the present are issued weekly or bi-weekly during April, May, June, September and October, will be mailed free to those who are interested.

At the closing session of the International Geographical Congress, on April 3, it was agreed that the next congress should be held at St. Petersburg.

THE wireless telegraphy station of the Ohio State University did excellent service during the recent flood. When communication by telephone and surface telegraph with other cities was cut off, the wireless became the only means of reaching the outside world.

Messages were sent to Cleveland and the University of Michigan and relayed from those stations by wire to their destination.

THE ninth annual meeting of the Prehistoric Congress of France will be held at Lons-le-Saunier from July 27 to August 2, 1913.

THE forty-fourth annual meeting of the German Anthropological Society will be held at Nurnberg from August 3 to 9, 1913.

At the eighty-sixth convocation of the University of Chicago, held on March 18, announcement was made of the election of thirty-five students as members of Sigma Xi for evidence of ability in research work in science. Six of these were women.

WE learn from the British *Geographical Journal* that news has been received in Holland from an official source that Mount Carstensz, the highest known summit of the snowy range of western New Guinea, has been successfully ascended by Dr. A. F. R. Wollaston, accompanied by Lieutenant van de Water, of the Dutch army. This, it will be remembered, was the chief task which Dr. Wollaston (who had taken a leading part in the previous expedition to Dutch New Guinea, organized by the British Ornithologists' Union) had set himself when undertaking his new expedition, and he is to be congratulated on successfully accomplishing his object. The height of the peak has been variously estimated, being thought for a time to reach an altitude approaching 18,000 feet. Recent surveys, however, especially those of the previous British expedition, had given reason for reducing the height to something under 16,000 feet.

A DEPUTATION from the Eugenic Education Conference recently held in London had an interview with Mr. Trevelyan, parliamentary secretary to the Board of Education, on April 2, asking that an inquiry should be held as to the advisability of encouraging the presentation of the idea of racial responsibility to students in training and children at school. The deputation, which was headed by Major L. Darwin, president of the Eugenics Education Society, stated that it was not desired that eugenics should be an extra subject in

the curriculum, or that it should be required to be taught by unwilling teachers, but it urged that the training college curriculum should be adapted to include the biological and physiological knowledge on which a eugenic ideal could be based, and that the subject should be approached from the evolutionary standpoint. Mr. Trevelyan said that the board, while unable to make sex hygiene or eugenics a compulsory subject of instruction in elementary schools or training colleges, recognized the importance of the matter, and had no wish to discourage experiments in teaching on those lines.

It is stated in the *Electrical World* that several pieces of electrical apparatus constructed by Volta during his early electrical experiments were discovered recently by Sir Henry Norman, a member of the British parliament, in a little curiosity shop in an out-of-the-way section of a small Italian town. The uncle of the shopkeeper was Volta's cook and body servant for thirty years. On his death he left much of his experimental apparatus with this servant, and it has since passed down from generation to generation. The collection comprises a cupboard full of old apparatus, a number of books, portraits, papers and letters and some personal and domestic articles. Sir Henry Norman suggests that the collection be purchased and presented to the Royal Institution to be placed with Faraday's original apparatus.

#### UNIVERSITY AND EDUCATIONAL NEWS

THE will of the late Isaac M. Jackson, of Plymouth, Mass., among other public bequests, gives \$15,000 to Yale University.

It is reported that the medical department of Willamette University, Salem, has been merged with the medical department of the University of Oregon, located at Portland, the merger to take effect at the conclusion of the present college year. There will hereafter be but one medical college in the state. A biennial appropriation of \$45,000 has been made by the Oregon legislature for the medical department of the state university.

THE development of a health instruction bureau in connection with the Extension Division of the University of Wisconsin has been authorized by the regents. According to authorities in medicine, hygiene and vital statistics, the average duration of human life could be raised fifteen years if all the present available medical and hygienic knowledge were intelligently applied. The new health bureau will undertake to carry out to the people of Wisconsin this knowledge. Bulletins will be published on preventable diseases, infant mortality, hygiene and similar subjects. Public lectures, health institutes, etc., will also be given.

PROFESSOR ALLYN A. YOUNG, of Washington University, St. Louis, has been appointed professor of economics at Cornell University, to succeed Professor E. W. Kemmerer, now of Princeton University.

#### DISCUSSION AND CORRESPONDENCE

##### A METHOD FOR MAKING PARAFFIN BOTTLES FOR HYDROFLUORIC ACID

THE usual method of making containers for hydrofluoric acid for use in softening hard woody tissue is, either to use the large wax bottles in which the acid comes from the dealer, or ordinary glass bottles which have previously been coated on the inside with paraffin. Owing to the size of the bottles the first of these methods is inconvenient, unless a large number of blocks of wood are to be softened at one time, and the second method is often unsatisfactory, as the paraffin sometimes cracks, allowing the acid to eat through the glass. These difficulties led me to devise the following bottle which is easy to make and is more satisfactory in its operation than the above.

Ordinary cardboard mailing tubes, of the proper diameter, should be cut into lengths of about ten centimeters each. These should be thoroughly infiltrated by placing them in a vessel of melted paraffin and leaving them in the oven for a short time. After the cardboard has become infiltrated the tubes should be removed, and when the paraffin has hard-

ened, they should be set on end on a cool moist surface and enough melted paraffin poured in to form a bottom four or five millimeters in thickness in each of the bottles. After cooling, each bottle should be filled with melted paraffin and emptied, a process that should be repeated every few minutes until a rather thick coating has formed on the inside. The exterior should be treated in a similar way by dipping the bottles into melted paraffin.

Rubber stoppers can be fitted to these bottles by warming the neck of each and by pressing a stopper, of the proper size, into the opening before the paraffin cools. If rubber stoppers are not available, ordinary bottle-corks, which have been coated with paraffin, can be used with quite as good results.

ALBAN STEWART

UNIVERSITY OF WISCONSIN

#### NOTES ON CUBAN FRESH-WATER FISHES

WHILE collecting fossils in the province of Santa Clara, Cuba, in 1911, my work took me to Baños de Ciego, Montero, 30 miles north of Cienfuegos. Here occur three hot springs having a temperature, respectively, of 93, 96 and 99 degrees Fahrenheit. These springs are grouped close together, not more than 20 yards apart and about 200 yards from the Analla River into which they drain. The springs of 93 and 96 degrees temperature are walled in and the latter is surrounded by a hotel. The one of 99 degrees temperature is of largest volume and has direct communication with the river. In this spring as well as in the drainage water of the other springs and the cold water of the river, I found a great many fishes, mostly viviparous.

The following species have been identified from the spring:

- Symbranchus marmoratus* Bloch.
- Gambusia puncticulata* Poey.
- Glaridichthys falcatus* Eigenmann.
- Girardinus matallicus* Poey.
- Pacilia vittata* Guichenot.
- Heros tetracanthus* (Cuv. & Val.).

Of these the eel-like *Symbranchus marmoratus* was found only in the hot spring. The

other species, so far as I was able to observe, were common to both the cold water of the river and that of the hot springs, becoming acclimated by degrees, until they were finally able to live in the hottest water, 37° Centigrade, approximately that of blood temperature.

I was curious to know if it were possible for these fishes to live equally well in the hot spring water of 99 degrees temperature and the river water of 60 degrees temperature without first going through a process of acclimatization, so conducted a number of experiments. It was quite evident that fishes could gradually come from the cold water into that of the hottest temperature, so I took a number from the hot spring, carefully catching them in a net so as to avoid injury and placed some in river water and others in water from the other springs. Those placed in water of 93 degrees temperature seemed to live in it as well as in that of 99 degrees, but those placed in river water, out of eleven fishes, nine died within ten minutes. The other two lived.

This experiment was repeated several times with similar results; more than two thirds failing to resist the sudden change of temperature.

I am unable to tell whether those used in the experiments were *Gambusia puncticulata*, *Glaridichthys falcatus*, *Girardinus metallicus* or *Pacilia vittata*, but probably they were mostly the latter genus and species, as this form was most abundant in the Chapapote spring.

While living in the hotel during a heavy storm the Analla River overflowed, sending a branch across this Chapapote spring. The following day we pumped out the water, finding a great many viviparous fishes, probably all of the four determined small species and a number of *viajecos*, *Heros tetracanthus*. Evidently they had all become acclimated to the hot water during the time of this overflow.

Besides the species mentioned, the collection contains two species which were not found in the warm spring, *Gambusia punctata* Poey, of which two were obtained from the Rio Analla and several from a tributary of the Zaza, and

*Glaridichthys torralbasi* Eigenmann, represented by one specimen from the latter locality.

BARNUM BROWN

#### SCIENTIFIC BOOKS

*A History of Geographical Discovery in the Seventeenth and Eighteenth Centuries.* By EDWARD HEAWOOD, M.A. Small 8vo. 475 pages. Cambridge University Press.

This work is one of the Cambridge Geographical series, its author being librarian to the Royal Geographical Society. Its aim is to deal with the less known period which followed the great discoveries of the fifteenth and sixteenth centuries. The author defines his period as "that in which, after the decline of Spain and Portugal, the main outlines of the world-map were completed by their successors among the nations of Europe." The book is therefore a narrative mainly of the explorations of Great Britain, Netherlands, France and Russia. The sphere of the French was largely in North America, and Russian endeavor was devoted to northern Asia and its adjoining seas, while it was left to the English and Dutch navigators to fill in the map of the remote seas and distant lands of the globe.

At the close of the period the map of the world was distinctly modern, though it remained for the explorers of the nineteenth and twentieth centuries to fill in most of the map of Africa and of the polar regions, and to make more advanced surveys and detailed study of all lands and seas.

The author is hampered by the necessity of crowding a vast amount of material into a small volume, which is an encyclopedia in outline, and hence lacks continuity, and interest for the general reader. Hundreds of localities and explorers are noticed, each in a sentence or two, with the barest statement of what the explorer did, or tried to do. But this is probably the fault of the series as planned, and not of the author. In a few instances he has given a relatively full and keenly interesting narrative, as, for example, of Tasman, Anson, Hudson, Cook and Vancouver.

About sixty illustrations contribute substantially to the value and interest of the volume. These include many maps belonging to the period, and several portraits of the more eminent navigators. Considering its small size, about four hundred pages of text, the work is well suited for reference, particularly by reason of the thoroughness with which the index has been prepared. This occupies about fifty double-column pages and contains several thousand entries.

ALBERT PERRY BRIGHAM

*Terminologie der Entwicklungsmechanik der Tiere und Pflanzen.* In Verbindung mit Professor C. CORRENS, Professor ALFRED FISCHER, Professor E. KUSTER von Professor WILHELM ROUX. Leipzig. 1912. Pp. xii + 465.

This book represents a type of purely scientific publication which has been scarcely attempted as yet in this country for any field of the biological sciences. As Professor Roux points out in the preface of the book, the development within recent years of analytic investigation in biology has brought about the development of a new terminology, especially in connection with embryology and inheritance. The purpose of this book is to make it possible to determine readily the meanings given to new terms by their authors, as well as the special meanings which many terms have acquired in connection with experimental and analytic investigation. That a real need for a book of this sort exists Professor Roux regards as evident because, as he says, the previously published terminologies of zoology, biology, medicine, etc., have for the most part omitted the special terminology of developmental mechanics.

The book defines some eleven hundred terms, purely philosophical terms being excluded and botanical and zoological terms being combined as far as seemed advisable. But that the book is far more than a simple dictionary will be evident from the fact that the eleven hundred terms occupy nearly five hundred pages. In many cases reference is made not

only to synonyms, but to related terms, and for most of the new terms which have appeared in connection with analytic work the author's name and the year, or in some cases the full bibliographic reference is given. In addition to this for many of the more important terms the subject-matter consists not simply of a definition, but of a short article of cyclopedic character. For example, under "Correlation" there are two pages of definitions, analysis, references, etc., under "Erbformel" one page, under "Experiment" almost five pages, under "Faktor" two pages, under "Heteromorphose" more than two pages. "Potenz" has nearly two pages, "Regeneration" nearly three pages, "Reiz" with compounds and adjective terms six pages, "Vererbung" five pages, etc. Each definition or article is signed with the initial of its writer.

Many terms consisting of substantive and adjective and a considerable number which consist of several words are included, *e. g.*, "adventive Bildungen" "erbgleiche Bastarde," "funktionelle Hypertrophie," "ontogenetisches Causalgesetz," "correlative Variabilität," "Gesetz der Concordanz der Zellteilung," "Lage der Teile im Ei und Embryo," "Lysintheorie der Entwicklungserregung." The alphabetic arrangement of such terms in the book does not follow any invariable rule, but is determined by the most characteristic word.

Every student of "developmental mechanics" is familiar with Professor Roux's pioneer work in the development of an analytic terminology as well as in analytic investigation, and it is of course to be expected that no inconsiderable portion of the book is devoted to the terms of which he is the author.

In general the book has a distinctly morphological cast, as might be expected from its title and its authors, but a considerable number of strictly physiological and some physical and chemical terms are briefly defined. It seems possible that in an eventual second edition some expansion along these lines may perhaps be desirable.

The following quotation from the preface suggests how the book may be used not merely

for reference, but as an introduction to the subject:

Wer diese Terminologie zu seiner Einführung in die Entwicklungsmechanik verwenden will, dem ist zu empfehlen, der Reihe nach mit der Lektüre der Artikel: Entwicklung, Entwicklungsmechanik, Analyse, Differenzierung, Faktoren, Determination, Autoergie, Potenz, Lebewesen, Funktionen, Wachstum, Anpassung, Perioden, Experiment zu beginnen und die in jedem Artikel befindlichen Verweisungen zu benutzen.

The publishers, the firm of Wilhelm Engelmann in Leipzig, have done their part in the manner to be expected of them: the book is convenient in form and size, the type is sufficiently large for perfect ease in reading and the typographic work is of the highest grade. In a rather extended examination of the book the reviewer has not noted a single typographical error.

There can be no doubt of the value of the book. It should be of great assistance to clearness of thought and expression and should decrease the number of new terms which have no excuse for existence except their authors' ignorance of terms already existing. It is to be hoped that the book may be widely used by experimental zoologists in this country as well as in Germany.

C. M. C.

*Handbook of Nature Study.* By ANNA BOTSFORD COMSTOCK. Comstock Publishing Co., Ithaca, N. Y. 1912. Pp. xvii + 938, many illustrations, mostly from photographs.

Wherever else the nature-study enthusiasm may have subsided, it has not at Cornell nor in New York. The principal reason for this steadfastness is the presence and work at Cornell of Mrs. Comstock. She has had loyal support from Professor Bailey, and effective helpers in a half-dozen assistants and associates, but she it is who has been, and is, the burning center of the Cornell nature-study illumination.

To make the rays reach farther Mrs. Comstock has for twenty years issued the well-known informing leaflets of the Home Nature-Study Course, which have gone to thousands of teachers and homes in New York. To make

the Cornell light shine farther still Mrs. Comstock now issues this monumental handbook, which is so full of meat for nature-study teachers that it almost requires both hands to lift it. A thousand clay-coated pages are too many and too heavy for one volume. The book is already being brought out in two-volume form, animal study filling one volume, and plant and earth and sky study making up the second.

There is an amazing amount of information, very well digested and arranged, about animal and plant life and earth and sky, in the book. It is an encyclopedia for the nature-study teacher, and it is at the same time a manual of nature-study practise. It contains the facts and, also, precise directions for using them in the most approved way; most approved, that is, by the actual experience, during the last fifteen years, of Mrs. Comstock, her associates, and the many teachers who have been under her eyes in New York.

The book is prepared, confessedly, to meet the general condition of untrainedness in nature study on the part of school teachers. This lack of training includes a lack of knowledge of nature, and hence a lack of knowing what there is to see. Mrs. Comstock's book has for each of its subjects, a "teacher's story" which tells facts, and then a "lesson," based on these facts, for the teacher to use with the children. The lesson includes a "leading thought" which determines the special observations called for, a note on the special "methods" to use for the particular lesson, and then a set of "observations" put in question form. In each lesson, too, there are book references for the teacher to make use of, if desired, and usually a bit of quoted verse or prose from some writer who has, of his own initiative had a lesson in seeing, enjoying and loving nature, from the special subject in hand. There are, too, hosts of pictures, most of them very attractive ones made from photographs of live plants and animals, and there is a detailed table of contents, extensive list of books for reference, and a full index. The book is altogether practically made.

Where nature study has weakened Mrs.

Comstock's "Handbook" should help it; where it has not yet taken root at all, the "Handbook" should go far toward giving it a beginning. For teachers and parents it should be *the* book of American nature study.

V. L. K.

STANFORD UNIVERSITY

#### JONGMAN'S PALAEOBOTANISCH LITERATUR<sup>1</sup>

THE third volume of Jongman's paleobotanical year-book has just been received in this country. It covers the years 1910 and 1911 and includes such titles as were omitted in the enumeration for 1908 and 1909. The arrangement is the same as in the two previous volumes, that is to say, the book is divided into two parts. The first part is a bibliography arranged chronologically by authors, each author's contributions being numbered, starting with number one for the first contribution in 1908 or subsequently. The second part, comprising pages 41 to 569, consists of a complete analysis of the literature listed in Part 1, and like it arranged alphabetically.

The real usefulness of a work of this kind depends entirely upon the skill and thoroughness with which the literature is digested, and in this respect Jongman's work seems to the writer to be of a much higher grade than that of comparable bibliographic undertakings. All old as well as new species discussed during the year are included, as well as all geological horizons, anatomical, morphological and phylogenetic contributions; all living species with which fossil species are compared, as well as purely botanical studies of such living forms as promise to shed light on fossil forms.

The work in short is exceedingly useful and botanists and paleobotanists are under a heavy debt of gratitude for the manner in which Dr. Jongman carries through this exceedingly laborious task. It is to be hoped that it will furnish the inspiration to some one to undertake a similar work for paleozoology.

<sup>1</sup>"Die Palaeobotanisch Literatur," Dritter Band, Die Erscheinungen der Jahre 1910 und 1911 und Nachträge für 1909, Fischer, Jena, 1913, 570 pages.

It is proposed to issue this paleobotanical volume each year. This laudable intention in a measure depends upon the acquisition of a regular subscription list and it is to be hoped that individual botanists and geologists as well as institutions will make the absurdly small expenditure that will insure the permanence and prompt appearance of this work.

EDWARD W. BERRY

JOHNS HOPKINS UNIVERSITY

*The Aborigines of Minnesota.* A Report based on the Collection of JACOB V. BROWER and on the Field Surveys and Notes of ALFRED J. HILL and THEODORE H. LEWIS. Collated, augmented and described by N. H. WINCHELL. Published by the Minnesota Historical Society. Illustrated by 36 half-tone page plates, 26 folded inserts and 642 figures inserted in the text. St. Paul, Minn., The Pioneer Company. 1911. Pp. xiv + 761.

This profusely illustrated monograph contains a mass of useful archeological and ethnological information, much of which is a monument to the scientific activities of the late Jacob V. Brower. Pages 1-579 treat of the Dakota, with some notes on the related Winnebago, etc.; pages 580-731 of the Ojibwa; while in appendices (pp. 732-743) are given Brebeuf's account of the solemn feast of the dead, from the *Jesuit Relations*, an account of the battle of Pokegama, from *SCIENCE* of 1886, a part of the *Walum Olum*, a tradition of the Delaware Indians, etc. A good index adds to the value of the book. Besides historical and geographical information, data as to treaties, and a detailed record and description (occupying pages 77-379) of earthworks in Minnesota, there are sections on the habitations, implements and instruments, manufactured articles, ornaments, food, pipes and smoking—also matter relating to death and burial, dances and "medicine," traditions, myths, etc., pictographs. A good deal of bibliographical material is included—on pages 25-62 is an annotated list of old maps of the Minnesota country, on pages 575-579 a partial bibliography of the Dakota, and on pages 707-

731 (two columns to the page) a valuable list of Ojibwa personal names.

In connection with the discussion of the "pre-Indian inhabitants of Minnesota" (pp. 1-23) one should read the recent studies of the antiquity of man in North and South America by Dr. A. Hrdlicka, and remember also that no convincing evidence of the existence of "*pre-Indian* inhabitants" of the new world has as yet been produced, either for Minnesota or for any other region of this continent. Nor can one rightfully speak of "the Eskimo quartz-workers of Minnesota" (p. 18). That the Algonkian stock preceded the Siouan in the occupation of Minnesota (p. 76) is an opinion here associated with the belief that "the Algonquian area in Colorado, shown on Powell's map of linguistic stocks, is perhaps a very ancient home of that stock," but this view is hardly to be approved. The Catawban area on the Atlantic (Carolinian) seaboard is taken as the "post-Glacial starting-point of the Siouan stock."

The recognition of "pre-Dakotan" mound-builders in Minnesota must be considered doubtful, but it is quite right to state (p. 408) that "there has been found in Minnesota nothing that would warrant the assignment of the mounds and effigies to any people enjoying superior culture or higher intellectual rank than the Indians who inhabited the state at the coming of the whites." Moreover, "in Minnesota there has not yet been discovered any evidence that the earthworks were designed for sacrificial purposes, nor for any religious ceremonies, nor primarily for points of observation," and, with the exception of the effigies, "there is nothing symbolic in their shapes or in their distribution."

Among the pictographs figured are a number from sandstone caves in Houston and Winona counties. The pictographs, attributable to the Dakota rather than to other Indian peoples, "belong in one grand category" and exhibit "a uniformity of style which points to but one people." The chief Algonkian inhabitants of Minnesota were the Ojibwa, but, according to the authors (p. 581),

there were pre-Ojibwa Algonkians in this region—probably the Cheyenne. Altogether, there is much good information and not a little speculation of a somewhat doubtful character in this volume. Some of the material deserves to be gone over again and made more of.

#### THE NATURE OF THE SUBSTANCES WHICH CAUSE THE BIOELECTRICAL POTENTIAL DIFFERENCES

In previous papers<sup>1</sup> we have shown that the potential differences at the junction of the *intact* surfaces of plants and aqueous salt solutions exhibit sharply defined and reversible changes with the change in the concentration of the salt solution. The sense of these changes is such that we can speak of a reversibility for cations and the order of magnitude corresponds nearly with that calculated by Nernst's formula. A similar change was ob-

of the order of magnitude of the so-called current of injury found in living organs. Finally we observed that the bioelectrical potential difference approaches a limit for increasing concentrations of the salt solution.

These characteristics are so definite that we undertook an investigation of the nature of the substances which are responsible for the potential differences at the junction of living organs and aqueous solutions. It was first ascertained that solid proteins, like gelatine or coagulated white of egg, show none of the potential differences characteristic for living organs. These characteristics were shown, however, by certain fatty compounds, like phosphatides (lecithin and kephalin), oleic, stearic and palmitic acids, and to a lesser degree by triolein. For technical reasons it was necessary to dissolve these substances in guaiacol or kresol.<sup>2</sup>

At the junction of a soluble lecithin solution and aqueous solutions were found the same changes in E.M.F. with the change in the concentration of the salt solution as we had

<i>m</i> /10 KCl	+ .042 volt >	.042 volt		
<i>m</i> /10 HCl	± .000 volt			

served on the *injured* surface of certain plants and on animal organs.

We found, moreover, that the potential difference becomes smaller if we substitute an equimolecular acid solution for the salt solution, and we pointed out that this difference is

<sup>1</sup> SCIENCE, XXXIV., 884, 1911; XXXV., 970, 1912. *Biochem. Ztschr.*, 41: 1, 1912; 44: 303, 1912.

previously found at the junction of a living organ (*e. g.*, the leaf of *Ficus elastica*) and the aqueous solution, and moreover we noticed also the characteristic acid effect. In order to show to what extent the electromotive behavior of a lecithin solution resembles that of

<sup>2</sup> Beutner, *Jour. Amer. Chemical Society*, 35: 344, 1913.

certain living plant organs, we will publish the results of two series of experiments, one on a 10 per cent. solution of lecithin in m-kresol and the other on the leaf of *Ficus elastica*. In both experiments the E.M.F. at the junction of these bodies and aqueous solutions of various concentrations was measured.

The differences observed for the same degree of dilution are almost identical in both cases and the drop in potential, if we substitute  $m/10$  HCl for  $m/10$  KCl, corresponds for a 10 per cent. lecithin solution to the change observed in the case of the intact apple or leaf of *Ficus elastica* under the same condition.

We obtained similar effects with chemically pure cephalin which Dr. Levene was kind enough to give us, and with triolein, oleic, stearic and palmitic acids dissolved in guaiacol or kresol. The kresol and the guaiacol without these lipoids gave concentration effects of a much smaller order of magnitude. Cholesterin gave no concentration effects.

We then made experiments with extracts of the apple in guaiacol and this extract gave the same results as the apple itself.

We may therefore conclude that the concentration effects on the E.M.F. observed in certain plant organs are due to the fact that these organs possess a surface consisting of a phosphatide or some fatty substance. It would be wrong to conclude that the same is true for the surfaces of all cells or organs. In a number of organs, *e. g.*, the striped muscle, the concentration effects are extremely small and it requires further experiments to explain their electromotive behavior.

#### METEOR DUST AS A MEASURE OF GEOLOGIC TIME

SOME years ago<sup>1</sup> I suggested a possible method of measuring the rate of formation of strata, and so of geologic time, by the proportion of meteor dust contained in the strata,

<sup>1</sup> Annual report Michigan Geological Survey, 1901, p. 243.

which method seems, now, to be really practical. Meteorites are continually striking the earth. According to the Britannica, 20,000,000 visible meteorites strike the earth each day and the telescope might reveal twenty times as many. I then assumed that they weighed a gram and were 10 per cent. nickel. This would mean 28.6 grams of nickel per square kilometer, per year. Professor W. H. Pickering has shown reason to believe that the visible meteorites are 15 to 18 cm., or, at any rate, 5 to 7 cm. in diameter,<sup>2</sup> and Farington<sup>3</sup> finds for the average specific weight 7.8 and for the average per cent. of iron and nickel, in a large number of meteorites, 72.06 and 6.5, respectively. Assume that the invisible meteorites make up for any exaggeration in Pickering's largest figure and that we have 7,300,000,000 meteors, weighing 23,700 grams each, striking the earth in a year, and we would have 340,000 grams per square kilometer of cosmic material per annum, of which 20,000 grams are nickel.

The .001 to .0001 grams per square meter of partly cosmic dust found on a 30-millimeter layer of granular snow by A. E. Nordenskjöld,<sup>4</sup> Lat. 80° N., Long. 15° E., might be a small part of the year's accumulation.

The redness of the residual red clay may be due to the cosmic dust slowly added in this slow process. This should also be a large part of the abysmal red clay of the great depths of the ocean. Of this red clay one square kilometer, one meter thick, would make 2,500,000 tons, if the specific gravity is 2.5. It contains, according to Clarke,<sup>5</sup> 0.0077 per cent. more of nickel than the average igneous rock. Assuming the nickel of the

<sup>2</sup> *Astrophysical Journal*, 1909, p. 378; 1910, p. 89.

<sup>3</sup> Field Museum of Nat. Hist., Pub. 151, pp. 213-14.

<sup>4</sup> *Poggendorff's Annalen*, Bd. 151 (1874), p. 158. See also "Studien und Forschungen veranlasst . . . Norden," von A. E. Nordenskjöld, Leipzig, 1885. *Journal f. prakt. Chemie*, N. F., Bd. 9 (1874), pp. 356-67.

<sup>5</sup> Data of Geochemistry, U. S. G. S. Bulletin 330, pp. 490 and 27 (.0307 and .023).

igneous rock to fairly represent the volcanic ash, which is another large part of the abyssal clay, a meter thick would contain 192.5 tons of nickel extra per square kilometer. It would take 8,700 years to accumulate this extra 192.5 tons of nickel in a meter at the rate of 20,000 grams per year. Now the red clay has, certainly, formed very slowly, as shown by the abundance of sharks' teeth and whales' ear bones, as well as the manganese and meteor dust.\* The man in the world best qualified to guess in an after-dinner conversation expressed to me his guess that 500 feet of the red clay would represent all geologic time. At the above rate, 500 feet, *i. e.*, 152.5 meters, would equal 13,000,000 years. Now this is of the order of the figures of other estimates of the earth's age, suggestively near to other short estimates, when we see that we have taken Pickering's maximum estimate of the size of meteors. If we took Pickering's smaller figures for the size of the meteorites, we could get estimates of age as great as the larger estimates of the age of the earth.

My object, at this time, is to urge the members of the talked-of Arctic and Antarctic expeditions, or, in fact, any one in snowy climates, to complete Nordenskjöld's observations by finding the amount of cosmic dust in a large amount of snow, accumulated in a known time, determined by annual rings or otherwise. It may, also, be well to test especially for the amount of nickel in strata which are thought to have formed very slowly.

I have no doubt, also, that within this century, there will be drilled a hole in the bottom of the sea which will give us the other datum to be determined.

ALFRED C. LANE

TUFTS COLLEGE, MASS.

#### THE MILWAUKEE MEETING OF THE AMERICAN CHEMICAL SOCIETY

ALTHOUGH the American Chemical Society changed its time of meeting from winter to spring there was no falling off in the attendance at the Milwaukee meeting, for in spite of the distance

\* *Bull. Mus. Royal*, 1884, p. 35. "Sediment de Mer Profonde."

from many of the local sections some four hundred members gathered for the meeting, as well as thirty guests.

The council meeting was held on Monday evening, March 24, and it was voted that the next meeting should be held in Rochester, New York, early in September. Other business of a general character was considered and the reports of all committees received.

On Tuesday morning the following four papers were given in general session, and with the exception of the last were fully illustrated:

Joel H. Hildebrand: "Some Applications of the Hydrogen Electrode in Instruction, Analysis and Research."

D. M. Buck: "Copper in Steel. The Influence on Corrosion."

H. E. Howe: "Some Projection Experiments with Spectra."

Wilder D. Bancroft: "The Theory of Emulsions."

On Tuesday afternoon excursions were held to the plant of the Jos. Schlitz Brewing Company, to the gas and coke plant; and the works of the Pfister & Vogel Leather Company and the Vilter Manufacturing Company were also open to the members.

In the evening a complimentary smoker was held in the Fern Room of the Hotel Pfister, at which Mayor Bading of Milwaukee was present.

On Wednesday there were meetings at Marquette University of the Agricultural and Food Division, the Biological Chemistry Division, Industrial Chemists and Chemical Engineers, the Pharmaceutical Chemistry Division, the Physical and Inorganic Chemistry Division and the Rubber Section.

On Wednesday evening Professor Julius Stieglitz, of Chicago, gave a public lecture on "Combustion," which was largely attended by the members as well as by the citizens of Milwaukee, probably eight hundred people being present.

On Thursday the meetings of the Divisions continued and the Organic Chemistry and Fertilizer Divisions also met.

In the afternoon excursions were taken to Pabst Brewing Company and the Pfister & Vogel Leather Company and in the evening a subscription dinner was held at the Hotel Pfister.

On Friday seventy-five of the members went by special train to Madison, Wisconsin, where they were received by committees of the Wisconsin Section of the American Chemical Society and con-

ducted to the various places of interest in Madison. The chemical laboratories of the University of Wisconsin, the capitol and the forest products laboratory were visited. A luncheon was served to the visitors, at which President Van Hise presided.

All members of the society who went to the Milwaukee meeting were well repaid for the journey.

The following is a list of papers presented, with abstract where abstract was furnished:

#### GENERAL MEETING OF ALL DIVISIONS AND SECTIONS

JOEL H. HILDEBRAND: *Some Applications of the Hydrogen Electrode in Instruction, Analysis and Research.* (Illustrated.)

The change of hydrogen or hydroxyl-ion concentration during the neutralization of acids and bases, the precipitation of hydroxides, etc., gives a very remarkable insight into the nature of the reaction. This change can be followed by means of the hydrogen electrode, of which a simple form was described, together with apparatus allowing its potential to be easily determined with a voltmeter. Curves were thrown on the screen showing the variation of potential, and consequently of hydrogen and hydroxyl-ion concentration, during the neutralization of various acids and bases. From these it was pointed out how such things could be easily determined as the proper indicator to use in a given titration, the degree of hydrolysis of salts, the dissociation of weak acids and bases, the way to prepare normal salts where hydrolysis takes place, the effect of structure on the strength of organic acids, etc. Curves representing the titration of salts such as borax and sodium carbonate were shown and conclusions drawn similar to those just mentioned. Others were shown representing the precipitation of various hydroxides, from which could be drawn conclusions regarding the behavior towards various reagents and the separation from each other. Owing to the difference in solubility of magnesium and calcium hydroxides, magnesium can be titrated in the presence of calcium, allowing its rapid determination in limestone, etc. The same method can be used with a platinum electrode to determine the oxidizing power of solutions, illustrated by the titration of iron with bichromate, avoiding the use of the external indicator.

D. M. BUCK: *Copper in Steel. The Influence on Corrosion.* (Illustrated.)

H. E. HOWE: *Some Projection Experiments with Spectra.* (Illustrated.)

WILDER D. BANCROFT: *The Theory of Emulsions.*

#### DIVISION OF AGRICULTURAL AND FOOD CHEMISTRY

H. E. Barnard, *chairman*

Glen F. Mason, *secretary*

H. E. BARNARD: *The Status of Food Legislation in the United States.*

A brief sketch of the history of food legislation in the United States followed by a discussion of the various types of laws, such as the Pure Food Law, Meat Inspection Law, Sanitary Food Law and Cold Storage Law, enacted for the improvement and control of the food industry. The special features of each law are described and the methods employed in their enforcement detailed.

CARL L. ALSBERG, F. RABAK, H. H. BUNZELL and O. F. BLACK: *Studies upon Maize.*

W. D. BIGELOW: *The Equilibrium between Sugars and Sulphur Dioxide in Dried Fruit.*

The time required for sulphur dioxide and aldehydes to unite prevents the formation of this compound in fruit that is dried quickly by artificial heat, but permits its formation in fruits that require a number of days for drying. Thus evaporated apples are nearly free from sulphur dioxide, while sun-dried peaches and apricots contain considerable amounts. The content of the latter is much greater because of the practise in the packing-house of dipping the dried fruit in water and again sulphuring and packing in boxes without subsequent drying.

The gradual disappearance of sulphur dioxide in dried fruit depends on temperature and humidity. The dextrose sulphurous acid compound is quite stable but is broken up by water to a sufficient extent to form an equilibrium between this compound and the free sulphurous acid. The free acid is subject to evaporation and oxidation and the equilibrium is, of course, maintained by the hydrolyzation of an additional amount of the compound.

W. D. BIGELOW: *The Influence of Cooking on the Sulphurous Acid Content of Dried Fruit.*

The methods usually employed in cooking fruit were ascertained by 525 letters of inquiry sent to residents of 21 states. The usual method appears to be to soak a number of hours without previous washing and cook for one or two hours in the water in which it is soaked. During the cooking about 10 per cent. of the sulphur dioxide present is oxidized to sulphate and 25 to 35 per cent. of it is volatilized. Preliminary washing removes 2-3 per cent. of the sulphur dioxide, and 35-50 per cent. more is removed when the fruit is soaked overnight in two or three times its weight of water and the latter is poured off and

discarded. By the latter practise there is also lost from a quarter to a third of the soluble solids of the fruit.

EDWARD BARTOW: *The Effect of Chicago's Sewage on the Illinois River.*

Tests made during a dry season in July show a very low content of dissolved oxygen in the river as far down as the Marseilles dam. Below the dam there is a gradual rise as far as Peoria, below which there is a slight drop, followed by a rise and higher values throughout the remainder of the river. During high water and in colder weather more oxygen is present in the upper part of the river, but there is evidence that the sewage is carried farther down the stream. A study of the fish life of the river by Professor S. A. Forbes shows no fish present in the river above the Marseilles dam. There is an increase in the number of fish found in the lower part of the river and the amount of plankton is very much greater than before the opening of the drainage canal.

A. HUGH BRYAN: *The Polarization of Light-colored Sugar Solutions.*

In polarizing light-colored sugar solutions, such as syrups, honeys, extracts, etc., with saccharimeters, using white light, it is often hard to neutralize the field, one side possessing a bluish or greenish tinge and the other a white or reddish one. This results from differences in rotation dispersion of the sugar solution and quartz wedges. In order to reduce this to a minimum, the white light used as a source of supply for the polariscope should be filtered through a neutral solution of bichromate of potash. This removes the blue and violet rays which are the main disturbing ones. For solutions of sucrose, a layer  $1\frac{1}{2}$  cm. thick of a 6 per cent. solution or 3 cm. layer of a 3 per cent. solution has been found sufficient, while for commercial glucose the percentage composition should be double for the same layer of solution, that is, 12 per cent. for a  $1\frac{1}{2}$  cm. cell or 6 per cent. in a 3 cm. cell. Dark-colored sugar solutions naturally tend to filter the light. Hence, there is little trouble experienced when polarizing them without the light filter cell, but many sugar chemists use the cell in case of all polarizations.

SLEETER BULL and A. D. EMMETT: *The Protein and Energy Requirements of Fattening Lambs as Determined by a Study of American Feeding Experiments.*

In this compilation of the American literature upon the protein and energy requirements for fattening lambs, 49 experiments from 16 different

agricultural experiment stations were reviewed. The experiments embraced 259 lots of 5,005 lambs. The data were classified into four groups, lambs weighing 50-70 pounds, 70-90 pounds, 90-110 pounds and 110-150 pounds. The average daily consumption of digestible protein in pounds, the average net energy in therms, and the average daily gains were reported and summarized for each group.

JOHN G. DIGGS: *Analyses showing the Composition of the Different Grades of Commercial Pack Peas.*

This paper gives a complete analysis of the various grades of canned peas put out by a single packing concern. It was thought that in one plant where uniform methods were used in grading, sizing and packing a closer distinction might exist between the composition of the different brands or grades. The basis for determining the three brands was the gravity of the first pea. The average of analyses of grades of each brand show: the younger immature peas contain eighteen per cent. more water than the oldest ones, the crude fiber decreases from 10.25 per cent. to 7.15 per cent. (water-free basis) as the pea matures, starch increases from 41 per cent. to 53 per cent. with maturity, sugar decreases as the pea grows older.

JOHN G. DIGGS: *Some Abnormal Factors of So-called Farmers' Cider Vinegar.*

This paper gives the analysis of eighteen samples of supposed cider vinegar produced by cask fermentation. In many of the samples fermentation was found to have been arrested before completion, these samples containing high percentages of sugar. The maximum factors in grams per 100 c.c. were: acid, 10.25; total solids, 9.64; sugar, 5.97; non sugars, 5.06; and glycerine, .51. Some of the samples were watered and to some sugar and acetic acid had been added. The difficulty of manufacture of vinegar by this process without at least some training is shown.

J. T. DONALD: *Methods for the Accurate Determination of Saltpeter.*

J. O. HALVERSON: *The Modified Babcock Method for Fat in Sweetened Dairy Products—Ice Cream.*

The need of a rapid volumetric method for ice cream is shown. The Babcock test is not applicable to sweetened dairy products on account of the well-known charring action of the acid on the sugar. If the sugar solution could be readily drained off, the ordinary Babcock method could then be used. This is accomplished by centri-

fusing the fat to the top as in the Babcock test, then drawing off the acid-sugar solution through a small glass stopcock fused on near the bottom of the test-bottle. This is the essential modification in this method.

A new ice-cream modified test-bottle, graduated to 25 per cent. for an 18-gram charge, is shown.

Results of 350 determinations on different ice-creams show that results consistent with the Roesse-Gottlieb ether extraction method are obtained, though running 0.6 per cent. low. The residual fat lost in the drained-off acid-sugar portion is shown to average the same as that lost in the Babcock test of cream.

The maximum variation of the individual readings compare favorably with those of the Roesse-Gottlieb method.

The modified method in detail with numerous tables of data are given, also two figures of the modified Babcock test and of the modified test bottle.

P. W. HOLTZENDORFF: *The Separation and Identification of the Permitted Coal-tar Colors in Foods.*

The method is confined to the permitted colors. Advantage is taken of difference in chemical composition and extraction by immiscible solvents to effect separation. Identification tests are made on the dry color and in aqueous solution, after well-known methods, particularly the reactions obtained with concentrated  $\text{H}_2\text{SO}_4$ .

ARDEN R. JOHNSON and B. W. HAMMAR: *Specific Heat Observations on Milk and Cream.*

ARDEN R. JOHNSON and ROY E. SMITH: *A Thermal Method for the Determination of Ratio of Congealed to Uncongealed Moisture in Frozen Soils.*

A. MCGILL: *Some Phases of National Food Control.*

A. E. PERKINS: *A Simple and Convenient Method for Determining the Salt Content of Butter.*

This paper describes a method for the determination of salt by titrating a solution of 5 or 10 grams of butter in 20 or 30 c.c. of commercial acetone with silver nitrate, using potassium chromate as an indicator. The author states that the method yields results entirely comparable with the longer volumetric or gravimetric methods formerly used.

Equal parts of commercial alcohol and ether may be substituted for the acetone with equally good results.

A. E. PERKINS: *A Note Regarding an Absorption Tube and Receiver used in the Kjeldahl Nitrogen Determination.*

The author states that successful use has been made of a 2-inch glass funnel and glass jar with straight sides used as the absorption tube and the receiver, respectively.

He states that the advantage is the large surface of acid that is present for the absorption of ammonia vapors, and very little bubbling occurs. No trouble has been experienced with the acid striking back towards the distilling flask.

C. S. ROBINSON and O. B. WINTER: *The Nature of Nitrogenous Compounds in Peat Soils.*

This paper takes up the study of the protein content of peat soils. Van Slyke's method for the determination of amino nitrogen is used to study the amount of nitrogen converted into the amino form under various conditions of acid and alkaline digestion. About 27 per cent. of the total nitrogen was converted into the amino form on heating with 25 per cent. sulphuric acid 96 hours and about 50 per cent. by heating with 5 per cent. NaOH for 150 hours.

R. H. ROBINSON: *Some Chemical Changes taking Place during the Embryonic Development of the Chick.*

S. H. ROSS and N. HENDRICKSON: *A Simple and Efficient 20° C. Bacteriological Incubator.*

A very satisfactory 20° incubator was made from an ordinary refrigerator, size 20 in.  $\times$  29 in.  $\times$  46 in., by installing two heating coils, 0.2 ampere, and a disc type thermoregulator in the refrigerating compartment. The thermoregulator actuated a circuit breaker and connection was made to a lighting circuit. With care in regulating the amount of ice the temperature was easily maintained between 19.5° and 20.5° C.

J. F. SNEEL: *The Detection of Adulteration in Maple Syrup and Sugar.*

H. V. TARTAR and B. PILKINGTON: *A Comparative Study of the Composition of Hops Grown in Different Parts of the World.*

H. V. TARTAR and L. A. BUNDY: *A Note on the Soluble Arsenic in Mixtures of Lead Arsenate and Soap.*

J. BOSLEY THOMAS and EDGAR A. SANDMAN: *Some Results of the Hypochlorite Disinfection of the Baltimore City Water Supply.*

The period covered by this report extends from January 1 to December 31, 1912. Calcium hypochlorite was applied at the effluent of the im-

pounding reservoir just before the water entered a seven-mile conduit, in amounts of 1.0 part per million available chlorin from January 1 to July 15, and 1.5 p.p.m. from January 15 to the end of the year.

Samples were taken daily from the untreated water and from the treated water at the end of the tunnel as well as from the effluents of several storage reservoirs. These samples were examined for the bacterial count and members of the *B. coli* group, and averaged by months, the *B. coli* organisms being calculated to numbers per cubic centimeter by the use of portions of the samples varying by a multiple of ten from .01 to 100 c.c.

The results of the treatment of this water supply have been reductions varying between 92 and 99 per cent. in the bacterial count and almost entire elimination of members of the *B. coli* group, the reductions in these organisms being between 92 and 100 per cent., with 99.99 per cent. reductions during five months and 100 per cent. during two months of the year.

The reduction in the number of cases of typhoid fever occurring in Baltimore during 1912 is 31 per cent., compared with an average of the number of cases occurring during the years from 1906 to 1910, and 24 per cent., compared with the cases occurring during 1911, in the last six months of which the water supply was treated.

J. E. HARRIS: *Soil Acidity.*

EDWARD GUDEMAN: *Glucose Analyses.*

Determinations of the mineral constituents of confectioner's glucose, representing over 1,000 samples examined during the years 1902 to 1913, were submitted in chart form, the curves showing the maxima, minima and averages of the total ash, chlorides and sulphurous oxide.

The results show that no fixed ratio exists between these ingredients. The chlorides approximate two thirds of the total ash, figured as sodium chloride. The sulphurous oxide ( $\text{SO}_2$ ) seems to vary inversely to the other ingredients. The fluctuations in these ingredients are so great that determinations of mineral matter in glucose give no bases for judging the quality of the product.

The table following shows the great variation in the maxima, minima and averages for the years 1902 to 1913:

Total Ash:

Parts Glucose  
(D.S.)

Maxima : 84-158 parts to 1,000  
Minima : 30- 50 parts to 1,000  
Averages : 52- 82 parts to 1,000

Chlorides:

(NaCl) Maxima : 68-92 parts to 1,000  
Minima : 18-38 parts to 1,000  
Averages : 36-82 parts to 1,000

Sulphurous Acid:

( $\text{SO}_2$ ) Maxima : 160-350 parts to 1,000,000  
Minima : 10-165 parts to 1,000,000  
Averages : 60-240 parts to 1,000,000

DIVISION OF ORGANIC CHEMISTRY

Treat B. Johnson, chairman

William J. Hale, vice-chairman and secretary

LLOYD M. BURGHART and RALPH H. MCKEE: *The Action of Cyanimido Ether on Esters of Amido Acids.*

It has previously been shown that cyanimido ethyl formed an open chain compound by the elimination of prussic acid and that this is followed by the elimination of alcohol with the consequent formation of a ring of four carbon and two nitrogen atoms.

The evidence obtained indicates that there is first formed an open chain compound by the elimination of prussic acid and that this is followed by the elimination of alcohol with the consequent formation of a ring of four carbon and two nitrogen atoms.

The authors were unable in any case to bring about the formation of a similar eight-atom ring, though many trials were made using para amino-benzoic ethyl ester as a starting material.

F. W. HEYL, F. E. HEPNER, S. K. LOY: *Zygadenine. The Crystalline Alkaloid of Zygadenus intermedius.*

Among the poisonous plants of the range death camas is most abundant and is the cause of most cattle poisoning in Wyoming. In the work which has been taken up at the Wyoming Experiment Station, upon the problem of poisonous plants, this one has been examined first.

A crystalline alkaloid melting at 200°-201° and having the formula  $\text{C}_{23}\text{H}_{23}\text{NO}_6$  has been isolated and its toxic effects studied. It was found to be similar to veratrine.

F. W. HEYL and F. E. HEPNER: *Some Constituents of the Leaves of Zygadenus intermedius.*

The study of this plant was continued and the resin examined, as statements occur in the literature ascribing poisonous properties to this part of the plant.

The chemical and physiological study demon-

strated the inert nature of the resin and proved that the poisonous properties reside in the alkaloidal fraction entirely.

The substances isolated from the plant include quercetin, dextrose, a phytosterol, a hydrocarbon hentriacontane, oleic acid, linoleic acid, iso linoleic acid. The solid fatty acids present were stearic, palmitic and cerotic. A neutral substance to which no formula has been assigned was found in the ether extract of the resin, and this fraction also contained a polyhydric alcohol similar to puranol.

C. G. DERICK and J. H. BORNHANN: *Rearrangements of N-Acyl Aromatic Amines.*

The fact that intramolecular rearrangements of the *N*-acyl aromatic amines proceed in the direction to decrease their ionization is tested out for *N*-diacetyl, *N*-dipropionyl, *N*-acetyl anilines and their corresponding aminoketones. It is found to hold and is a very satisfactory criterion for the possibility of rearrangements of this type. The criterion is found to hold for the rearrangement of acetophenone oxime into acetanilide. By combining the senior author's measure of negativity with the above work, it is possible to state a limit beyond which two acyl-radicals must be substituted for the aminic hydrogen before rearrangement will be possible.

P. N. EVANS and LENA M. SUTTON: *The Efficiency of the Preparation of Ether from Alcohol and Sulphuric Acid.*

The completeness of the reaction was determined by comparing the fractionation results of the successive distillates with those of artificial mixtures corresponding to the theoretical products at various degrees of completeness; the efficiency proved to be about 40 per cent., and this was maintained until there remained in the generating flask a charred and semi-solid residue amounting to only about one twentieth of the original acid in weight.

The yield of distillate was in some experiments as high as 176 times the volume of the original acid, containing ether amounting to 40 times the volume or 16 times the weight of the acid used.

The final fall in efficiency was due, therefore, to the loss of sulphuric acid and not to the accumulation of water formed in the reaction. That the accumulation of water is not the interfering factor was further shown by the normal course of the reaction when dilute sulphuric acid was employed.

From 15 to 20 per cent. of the sulphuric acid

used was accounted for as sulphur dioxide. Other by-products are being further investigated.

BEN H. NICOLET and TREAT B. JOHNSON: *The Constitution of Surinamine.*

Surinamine, which was isolated by Giutyl in 1868 from a species of leguminous trees from Brazil (*Ferreira spectabilis*) is a methyl derivative of tyrosine,

and not a higher homologue,

This methyl derivative of tyrosine has been synthesized in this laboratory and found to be identical with the natural base, which was isolated by Giutyl. This conclusion has been confirmed by Professor Dr. Guido Goldschmidt, to whom we are indebted for a sample of Giutyl's original base.

TREAT B. JOHNSON: *A New Method of Synthesizing  $\beta$ -Ketone Esters.*

A new method of synthesizing certain types of  $\beta$ -ketone esters has been developed by the application of Refounatsky's reaction. Our synthesis represents the first phase of Refounatsky's reaction. Substituted ketone esters of the general formula  $\text{C}_6\text{H}_5\text{OCH}_2\text{COCH(R)COOC}_2\text{H}_5$  can easily be obtained by the action of esters of  $\alpha$ -halogenated acids on esters of hydroxy acids in the presence of amalgamated zinc. The method has been applied successfully in several cases.

LEWIS H. CHERNOFF and TREAT B. JOHNSON: *Pyrimidine Nucleosides.*

ROBERT BENGIS and TREAT B. JOHNSON: *New Thiohydantoin Condensation Products.*

A continuation of the hydantoin researches from the Sheffield Laboratory. This investigation deals with the possible precursors of the naturally occurring base adrenaline. By application of our own methods of synthesizing  $\alpha$ -amino acids from thiohydantoins, several new amino acids of biochemical interest have been prepared.

WILLIAM J. HALE: *The Constitution of "Acetyl-acetone-Urea."*

This compound is to be considered as a dimethyl-oxy-pyrimidine or dimethyl-pyrimidone. The presence of an hydrogen atom attached to one of the nitrogen atoms of the pyrimidine nucleus was proved by methylation with diazomethane.

W. A. NOYES and L. F. NICKELL: *Decomposition of Isodihydroaminocampophyllitic Acid with Nitrous Acid.*

Isodihydroaminocampholytic acid was prepared by the method of Noyes and Knight (*Jour. Am. Chem. Soc.*, 32: 1669). In the saponification of  $\beta$ -amidoisocamphoric ester some d-camphoric imide was formed. Isodihydroaminocampholytic acid forms the same anhydride as dihydroaminocampholytic acid; the free acid does not form an inner salt in solution. By decomposing this acid with nitrous acid, a hydrocarbon, d-campholytic acid, 1-trans-dihydrohydroxyecampholytic acid and 1-campholytolactone are formed. 1-campholytolactone on hydrolysis gives 1-cisidihydrohydroxyecampholytic acid. The Walden inversion occurs only in the formation of 1-campholytolactone, which is 1.8 per cent. of the acid decomposed.

R. S. POTTER and W. A. NOYES: *Are Ammonium Compounds Atomic or Molecular?*

The authors have shown that in amino camphonic acid the amino and carboxyl groups combine to form an inner salt. Similar acids, amino dihydrocampholytic, amino homo camphonic and amino homo dihydrocampholytic, probably do not form this inner salt. The above conclusions were arrived at through a consideration of the rotations of the acids mentioned, their hydrochlorides, sodium salts. The anhydrides and nitroso derivatives of the acids were also prepared. The conclusion as to the structure of the ammonium inner salt is taken as a refutation of Werner's theory of the structure of ammonium compounds.

O. A. BEATH and EDWARD KREMERS: *A Crystalline Resin Acid from the Digger's Pine.*

The oleoresin of *Pinus sabiniana* is of special interest not only because it contains heptane in place of pinene of the corresponding oleoresins of the genus *Pinus*, but also because its resin acid until recently defied all attempts at crystallization. A crystalline product has been obtained by two different methods.

C. D. GEIDEL and EDWARD KREMERS: *The Oxidation of Indigo Blue by Phellandrene "Peroxide."*

A preliminary report on the relative capacity for oxygen conveyance of phellandrene as compared with pinene and limonene.

EDWARD KREMERS: *Direct Halogen Substitution as a Laboratory Experiment in Organic Chemistry.*

Text-books have always emphasized the direct substitution of hydrogen of the methane series of hydrocarbons by halogen. Nevertheless, there possibly does not exist a laboratory manual to-day

which provides an experiment illustrating this important reaction. This is due, no doubt, to the absence of suitable hydrocarbon material. Such a material, however, can now be provided, if wanted, in the form of normal heptane from either the Diggers pine or Jeffrey pine of California. The substitution experiment can be supplemented by a series of reactions illustrative of Schorlemmer's classical experiments on the constitution of the paraffin hydrocarbons.

CARL O. JOHNS and EMIL J. BAUMANN: *Researches on Purines. 2-Methylmercapto-6, 8-dioxypurine and 2-Methylmercapto-6-oxy-8-amino-purine.*

2-Thio-4-amino-6-oxypyrimidine was alkylated in alkaline solution by means of dimethyl sulphate giving 2-methylmercapto-4-amino-6-oxypyrimidine. By means of nitrous acid this substance was converted to 2-methylmercapto-4-amino-5-nitroso-6-oxypyrimidine. This latter compound was reduced to 2-methylmercapto-4, 5-diamino-6-oxypyrimidine by means of ammonium sulphide. The diamino pyrimidine was heated with urea and gave 2-methylmercapto-6, 8-dioxypurine which on hydrolysis with hydrochloric acid gave uric acid. When the above-mentioned diamino-pyrimidine was heated with guanidine thiocyanate it gave 2-methylmercapto-6-oxy-8-aminopurine, which could also be hydrolyzed to uric acid.

CARL O. JOHNS and ALBERT G. HOGON: *Researches on Purines. 2-Thio-6, 8-dioxypurine; 2, 8-dithio-6-oxypurine; a New Method of Preparing Xanthine and Uric Acid.*

When 2-thio-4-amino-6-oxypyrimidine was heated with urea it gave 2-thio-6, 8-dioxypurine. When the latter compound was boiled with chloracetic acid we obtained 6, 8-dioxypurine-2-thioglycollic acid, which on heating with hydrochloric acid gave uric acid. When 2-thio-6-oxypurine was heated with chloracetic acid we obtained 6-oxypurine-2-thioglycollic acid. On hydrolysis with hydrochloric acid this gave xanthine.

When 2-thio-4-amino-6-oxypyrimidine was heated with urea it gave 2, 8-dithio-6-oxypurine. With chloracetic acid this gave 6-oxypurine-2, 8-dithioglycollic acid.

J. H. LONG: *Some Conditions Affecting the Stability and Activity of Certain Ferments.*

The action of certain body ferments on each other has been long discussed. As to the extent of this mutual action there is still much confusion, which is in a large measure due to a failure to give proper weight to the behavior of the medium in which the ferments act.

It is not possible to explain the action of pepsin on trypsin and amylpsin, for example, until the influence of the acidity, the alkalinity or the salt content of the medium is eliminated or fully defined. The paper deals with determinations in this direction, with special reference to the condition of amylpsin action. Glycerol extracts of the pancreas, as well as a number of commercial products were used in the investigations.

R. A. GORTNER: *Studies on the Chemistry of Embryonic Growth. I. Certain Changes in the Nitrogen Ratios of Developing Trout Eggs.*

The distribution of certain fractions of the nitrogen was determined in trout eggs at various stages of embryonic development, beginning with eggs less than 24 hours old and ending with the young fish which were ready to take food.

It was found that no nitrogen left the egg before hatching, but that the monamino-acid nitrogen diminished and a gain of basic nitrogen took place. No considerable amount of urea or uric acid was formed.

After hatching the nitrogen is rapidly lost, until 21 days after hatching 21.96 per cent. of the total nitrogen has been eliminated. At this period the total weight (dry at 100°) has diminished 25.35 per cent.; 37.26 per cent. of this loss being due to non-nitrogenous compounds (fats, etc.) and 62.73 per cent. to proteins ( $N \times 6.25$ ).

A study of the form of the nitrogen which is eliminated showed that nearly all of the basic nitrogen is retained in the new organism, nearly all of the nitrogen liberated being monamino-acid nitrogen.

The significance of these findings as regards our

present knowledge of the chemistry of embryonic growth, is discussed.

The paper will be published in *The Journal of the American Chemical Society.*

PHILIP ADOLPH KOBER: *The Nephelometric Determination of Proteins. I. Casein and Globulin in Milk.*

Results in previous papers showed that proteins can be rapidly and accurately estimated with a nephelometer. After removing the fat from milk, casein and other proteins may be estimated directly in this way. While the official method takes two or more days to determine casein, globulin and albumin in milk, it can be done nephelometrically in less than 30 minutes. The nephelometer described in a previous paper is shown with several improvements.

G. O. HIGBY: *A Study of Well Water as a Cause of Typhoid Fever.*

This investigation was begun in August, 1910, at Delaware, Ohio, because of the prevalence of typhoid fever in the city, there being 26 cases on August 1 in a city of 10,000 inhabitants. The hydrant water having been proved safe, suspicion fell upon the well water, and samples from 65 wells were collected and examined chemically and for the presence of the colon bacillus between September 1, 1910, and June 1, 1912.

Serious local pollution of the wells was discovered and reported to the city health officer, resulting in the closing of some wells and the cleaning and abandoning of many cesspools. The number of typhoid cases in the city has been as follows: 1909, 18 cases; 1910, 34 cases; 1911, 7 cases; 1912, 10 cases (seven of these on the outskirts of the city, where the water pipes have not been laid); 1913, no cases up to March 22.

L. KNUDSON: *Influence of Cane Sugar on the Production of Tannase by Aspergillus Niger.*

M. X. SULLIVAN: *Molds as a Factor in the Formation of Certain Nitrogenous Organic Soil Constituents.*

Some thirty-five to forty different substances have been found in the organic matter of the soil. In some of the soils, mold growth was very evident. Molds were taken from soil and implanted on Raulin's solution. After several replantings 70 liters in bottles were inoculated with what has been identified as a variety of *Penicillium glaucum*. After a period varying from three to five weeks, the mold mycelium and the culture solution were examined for various organic constituents. On the air-dried molds have been found, a trace

of xanthine, much hypoxanthine, some guanine, adenine, histidine, arginine in very small quantity, probably lysine, thymine, choline, mannite, pentoses, cholesterol bodies and lipoids resembling cerebroside, a small amount of an unidentified hydroxy-fatty acid, and large amounts of oleic and palmitic acid and some stearic acid. In the culture solution was found fatty acids, guanine, adenine and hypoxanthine, a small amount of histidine, pentose sugar, unidentified aldehydes, mannite and probably thymine. The general conclusion is drawn that molds, and other microorganisms play a considerable rôle in the formation of organic soil constituents.

J. J. SKINNER: *Effect of Salicylic Aldehyde as a Soil Constituent.*

The isolation and identification of salicylic aldehyde in soils is pointed out.

The effect of this soil organic compound on growth was studied by growing plants in nutrient culture solution, in soil and in sand.

In culture solutions salicylic aldehyde was very harmful to wheat, corn, cabbage and cow-pea plants, in amounts of 10 parts per million. Amounts from 50 to 100 parts per million killed the plants. The aldehyde was harmful in cultures containing phosphate, nitrate and potash, regardless of whether the salts were used singly or in combinations. The aldehyde in small amounts was also harmful when added to soil and to sand.

Forty-five unproductive and thirty productive soils from various parts of the United States were examined for salicylic aldehyde. Seventeen of the unproductive soils and three of the productive soils contained the aldehyde. The extracted soil aldehyde was tested in water cultures as to its effect on growth and in each case proved harmful.

MARY LOUISE FOSTER: *A Comparative Study of the Metabolism of Pneumococcus, Streptococcus, Bacillus lactis erythrogenes and Bacillus anthracoides.*

Two strains of pneumococcus grown at 37°-40° C. on serum with three parts of water showed that proteolysis is progressive, the largest phosphotungstic fraction being found at the highest temperature. Sterilized milk at 37° C., inoculated with streptococcus, bacillus lactis erythrogenes, or bacillus anthracoides showed hydrolysis of the native protein, diamino and monoamino acids being formed. The amount of monoamino acid increased with the time of the interaction.

L. W. FETZER: *A Biochemical Interpretation of the Inheritance of Acquired Characters.*

W. T. BOVIE: *The Chemical Effects of Ultra-violet Light on Albumin.*

Ultra-violet light causes egg white and crystallized egg albumin to coagulate and to give off a peculiar odor similar to the odor of burned hair. Coagulation can be produced while the albumin is cooled in ice water. The albumin is decomposed by the light. Lead-blackening gases are given off. Cystine and hydrogen sulphide are also decomposed. The coagulation and decomposition are produced almost entirely by the ultra-violet light not found in sunlight. Protoplasm is unstable in light of shorter wave-lengths than is found in sunlight. Life as we know it would be unstable in a world unprotected by an atmosphere at least as opaque as ours.

ALFRED DACHNOWSKI: *Plant Growth in Relation to Acid and Alkaline Solutions.*

A. P. MATHEWS: *The Nature of Irritability and the Action of Anesthetics.*

Confirming his earlier work, the author finds that the anesthetics act chemically, not physically, as generally supposed. By means of the method of computing valences in molecules, it is shown that all anesthetics have residual valences by which they may unite with protoplasm. Thus nitrous oxide has six valences, the oxygen having two free valences; the esters, alcohols, aldehydes have free valences on the oxygen; this is also true in the urethane group; in carbon monoxide, the free valences are probably on the carbon; in ether, on the oxygen; in chlorine compounds, on the chlorine; in bromine compounds, on the bromine; in carbon bisulfide and sulphuretted hydrogen, on the sulphur; in the cyanides and nitriles, on the carbon; in the terpenes, benzenes and aliphatic hydrocarbons some of the carbons are hexavalent. The case of dissociation of the anesthetic from the protoplasm also points to a molecular union. All anesthetics probably unite with hemoglobin, forming molecular unions similar to oxyhemoglobin. The interpretation offered of irritability based on the work of the author, Tashiro and others, is as follows: The irritable compound in most protoplasm is a molecular union with oxygen. This is unstable like oxyhemoglobin, which passes easily to methemoglobin. When stimulated in a variety of ways it passes into firm union, oxidation taking place. This is at the basis of most cell syntheses. The anesthetics act by displacing the oxygen from its molecular union, just as CO displaces O<sub>2</sub> in oxyhemoglobin, the anesthetics uniting by their residual valences in molecular

union with the oxygen receptors. Such compounds can not be oxidized by shock, hence respiration is reduced; conduction which is analogous to an explosion wave of oxidation is blocked; irritability is lost; growth and synthesis stops.

ARTHUR W. DOX and RAY E. NEIDIG: *Cleavage of Hippuric Acid by Molds.*

The formol-titration method of Sörenson was found admirably adapted to a study of enzymotic cleavage of hippuric acid. All of the mold species examined contained an enzyme capable of hydrolyzing 80 per cent. or more of the hippuric acid in the presence of toluol. The age of the culture (1 to 4 weeks) seemed to have little influence upon the amount of enzyme. The enzyme was produced in all cases in the absence of the corresponding zymolyte from the medium.

P. E. BROWN: *Bacterial Activities and the Rotation of Crops.*

GEORGE PEIRCE: *The Purification of the Esterase from Pig's Liver.*

The esterase is obtained by crushing pig's liver with sand, mixing with water and straining through cloth. The purification is accomplished by dialysis, half saturation with  $(\text{NH}_4)_2\text{SO}_4$ , rejection of ppt., complete saturation with  $(\text{NH}_4)_2\text{SO}_4$ , and dialysis of a suspension of this ppt. After filtration the solution will hydrolyze 200 times its weight (reckoned as dried material) of ethyl butyrate in 1 hour, the final acidity being N/100, the ethyl butyrate solution being about two thirds saturated (N/28).

The enzyme is strongly inhibited by NaF, the inhibition being due to an inert compound formed by the enzyme and the NaF. The amount of inhibition followed the mass law. A possible method of working out the maximum molecular weight of the grouping with which the NaF combined was indicated.

R. E. SWAIN and J. P. MITCHELL: *The Determination of Sulphur Dioxide in the Air.*

The sample of air is collected for analysis in a flask of about ten liters' capacity. The latter is fitted with a glass stopper carrying a dropping funnel and a short outlet tube. N/100 iodine solution (10 c.c.) and 150 c.c. of water are then added, and the flask and contents shaken vigorously for ten minutes. Stopper and fittings are rinsed off and removed, and N/100 arsenious acid added until only a faint brown color remains. The solution is finally rinsed into a titrating flask and the titration finished with starch as an indicator. Results on known amounts of sulphur dioxide indicate an error of less than five parts per million parts of air.

EDWARD KEEMERS: *The Methyl and Methylene Ethers of Phenols Found in the Vegetable Kingdom and the Light which they Seem to Throw on Certain Phases of Plant Metabolism.*

The importance which formaldehyde or its hydration product, the methylene glycol, plays in plant metabolism is universally recognized. The minor rôle played by the other reduction products of carbon dioxide has been largely overlooked. The rational classification of the methyl and methylene ethers of the phenols, together with that of glucosidal compounds of the phenols, seems to throw a ray of light on the rôle which these two simple alcohols play in common with the simple sugars.

WM. MANSFIELD CLARK: *The Analogy between the Formation of "Eyes" in Emmental Cheese and Crystal Growth.*

A review of the literature reveals no conclusive evidence that the characteristic holes or "eyes" of Emmental cheese are localized at points of great bacterial growth. The alternative, that the eye-inflating, gas-producing bacteria are more or less generally scattered throughout the whole body of the cheese is confirmed by the comparison of the gas production of eye walls and of solid regions distant from eyes.

That the gas produced by bacteria in gels may separate at points distant from the colonies, and that this gas separates preferably where a pre-formed bubble is already found has been experimentally demonstrated. Instances are also cited to show that large bubbles grow at the expense of small.

The theoretical reasons are presented as well as the analogy between the formation of gas

bubbles and the growth of raindrops and solid crystals.

From these principles it is deduced that with a rapid gas formation in cheese the gas must necessarily tend to separate at many points, each more or less near to colony growth, while with a slow gas production the gas has time to find its way to points where it may separate from solution most advantageously and then continue to form accretions. It was found by using curd superficially stained with Congo red which outlined each curd particle in the cheese, that "Nissler" holes which are small and rapidly formed were situated both within and between curd particles, while normal eyes universally developed between the curd particles, points long ago described by Bachlor as "weak spots" favorable to eye growth.

F. ALEX. McDERMOTT: *Chemiluminescent Reactions with Physiologic Substances.*

The products of the alkaline hydrolysis of pectone and glue, done in the absence of oxygen, give a faint light when oxidized with strong alkaline hydrogen peroxide, and a somewhat brighter light when formaldehyde is added before the peroxide. Urin may be caused to give light in a number of ways, particularly upon the addition first of formaldehyde and then of alkaline hydrogen peroxide. The cause of the latter phenomenon is not known.

F. ALEX. McDERMOTT: *A Note on an "Oil Nut," Pyralaria pubera (Buffalo nut).*

The fruit of *Pyralaria pubera* contains about 27 per cent. of oil. The cause of the astringent taste was not located.

ATHERTON SEIDELL: *The Analysis of Thymol Capsules.*

ATHERTON SEIDELL: *The Riegler Method for the Determination of Thymol.*

F. O. TAYLOR: *Interpretation of the U. S. P. Assay Processes.*

This paper deals with the possibility of different interpretations of the assay methods for alkaloidal drugs and their extracts as given in the U. S. P., with particular reference to some specific instances where discrepancies have occurred because of a

different understanding of the assay processes by various chemists. It directs special attention to the difficulties involved in transferring the alkaloid from an aqueous solution to one in chloroform or ether, or from these solvents to an acid aqueous liquid as is regularly done in these assay processes. Also some of the peculiar difficulties involved in the assay of the mydriatic drugs, and differences liable to be caused by variations in the method and time of shaking aqueous liquids with the immiscible solvents, and in the final titration of the alkaloidal residue where this volumetric method is used. Experimental proof is also submitted of the liability to such variations when these processes are applied by different men.

W. D. McABEE: *Patent Medicine Ethics.*

W. A. PEARSON: *Ergot.*

L. E. SAYRE: *The Recovery of Alkaloids when Precipitated by Alkaloidal Reagents.*

There is, of necessity, an appreciable loss of alkaloid in any analytical process designed for its recovery. A complete recovery is practically impossible. In certain analyses consisting of a separation of alkaloids from dilute solutions, it is frequently desirable to precipitate them by well-known alkaloidal reagents, as a first step in the separation and estimation. The question arises: What is the probable loss of alkaloid by such a preliminary step and subsequent treatment for recovery?

Operating upon four well-known alkaloids with different procedures for their recovery, certain data were obtained and tabulated. The authors feel this may be considered as a fair average of loss, this opinion being based upon a much larger number of experiments than are tabulated.

F. P. SUMMERS and CHAS. EARLE: *Oxysulphobenzide, its Presence in Commercial Phenolsulphonates.*

In applying the routine tests for phenol upon the various phenolsulphonates of the market, there was obtained an ether-soluble residue which in some of its properties resembled phenol. On further examination it proved to be oxysulphobenzide. This impurity has been found in quantities of 0.1 to 0.4 per cent. It is a white crystalline body melting between 215° and 231° C.

F. P. SUMMERS and H. McCAUSLAND: *Boldine, an Alkaloid from *Peumus boldus*.*

A brief résumé of the literature on the chemical constituents of *Peumus boldus* is given. The method of producing the alkaloid boldine is described. It is a white crystalline body melting at

185° C. (corrected). Boldine hydrobromide is also described. It is a white crystalline body melting with decomposition at 240° C. Tables of reactions with the various alkaloidal precipitants and other reagents are given. An empirical formula is promised for a subsequent paper.

C. H. BRIGGS: *The Determination of Uncombined Hydrochloric Acid in Solution Ferrie Chloride.*

The total chlorides are determined by titration with silver nitrate in acid solution. The combined chlorides are calculated from the amount of iron present and subtracted from the total chlorides, giving the amount of free hydrochloric acid.

O. A. BEATH and EDWARD KREMERS: *An Oleoresin of *Pseudotsuga taxifolia* (Lam.) Britton.*

A sample of this oleoresin was obtained through the cooperation of the Forest Products Laboratory. Its examination was undertaken with a view of throwing more light, if possible, on the possible sources of the so-called Oregon balsam. The physical and chemical constants of the oleoresin, the volatile oil and the resin were ascertained so far as the limited amount of material permitted.

EDWARD KREMERS: *Some Aspects of Pharmacopœia Revision.*

The conflict between the pharmacopœia as a codex and a scientific treatise is unnecessarily emphasized by the present mode of revision. This conflict and the attitude of certain critics is illustrated by means of data that have come to the attention of the writer in the work in which he is more particularly engaged. The revision of the

U. S. Pharmacopœia in the future should be carried out by a method of publication more in harmony with modern practise.

DIVISION OF INDUSTRIAL CHEMISTS AND CHEMICAL ENGINEERS

G. D. Rosengarten, *chairman*

M. C. Whitaker, *secretary pro tem.*

CARL A. NOWAK: *The Training of the Fermentologist.*

The constant demand on the part of the fermentation industries for university-trained men offers a profitable field of work for the young chemist. The future fermentologist should possess considerable specialized training in analytical and research work pertaining to the raw materials entering into these industries. The paper discusses the manner in which such scientific training is provided abroad, in England and on the continent, and points out that while, as yet, there is no such provision made at any of the universities in this country it does not seem improbable that with the financial assistance of the men interested in the fermentation industry this could easily be accomplished.

JOHN SAMUEL STAUDT: *The Training of the Technical Chemist.*

The paper makes a survey of what the training of the technical chemist is at present, and points out what the training of the technical chemist ought to be. A comparison and analogy of the training of the technical chemist is made with that of the civil, mechanical and electrical engineer. The paper reviews technical education as it exists in England, Germany and America, and makes a comparison of the methods in vogue.

In discussing what the training of the technical chemist ought to be, the writer points out what the world demands, and in what respects our present system of technical education is faulty. It advocates a more thorough study in the liberal arts and more cooperation between the university, or technical institution and the industries, favoring a permission of technical students to work for the cooperations during their summer vacations.

Graduate study as a direct continuation after graduation is not favored, but is recommended after a year or two in practise.

FRANCIS C. FRARY and M. GORDON MASTIN: *The Determination of Zinc in Treated Ties.*

Over nine million railroad ties were preserved by treatment with chloride of zinc in 1911. Practically all these are bought under the specification

that they must contain half a pound of zinc chloride per cubic foot. The method of determining the zinc after decomposing the wood of the sample with nitric and sulphuric acids, as generally used, is slow and troublesome, and with red oak ties it appears to be impossible to destroy all the organic matter. This prevents the precipitation of the zinc, and the result is that analysis of such ties will show less than half of the zinc actually present.

The authors have worked out a method of decomposing the wood by fusion with caustic potash and a little saltpeter, which removes every trace of organic matter, and leaves the solution in such a condition that the zinc can be determined by titration with potassium ferrocyanide solution. Accurate results are easily and quickly obtained. Check determinations with shavings from untreated red oak ties, to which known amounts of zinc chloride solution were added, showed that the recovery of the zinc was practically complete.

A. M. MUCKENFUSS: *Preliminary Report upon a Practical Accelerated Test for Paints and Varnishes.* (Lantern.)

S. W. PAER: *Coal Ash.*

EDWARD GUDEMAN: *Analyses of Glucose and Starch Sugars.* (See Agricultural and Food Chemistry.)

HORACE C. PORTER and GUY B. TAYLOR: *The Specific Heat of Coal and its Relation to the Presence of Combined Water in the Coal Substance.*

The specific heats of four coals were determined by the method of mixtures with an accuracy of 2 to 3 per cent. The values for dry coal ranged from 0.261 to 0.315, according to the type of coal, within the temperature interval 28°-63° C. A Wyoming sub-bituminous, of 11 per cent. moisture showed a value of 0.370. At higher temperatures the specific heats were higher.

Comparison of the specific heats of dried and undried coal shows the specific heat of the water present to be about 0.72 and indicated thus that the water is present in a state other than that of free superficial moisture. The facts also that heat is developed by the action of water on dry or partially dried coal, and that coal containing water has a vapor pressure considerably below the normal aqueous tension of free water, tend to support the theory of the presence of combined water, although the low vapor tension may possibly be explained also as due to capillarity or adsorption.

O. L. BARNEBEY: *Detection of Cyanides in the Presence of Ferri-, Ferro- and Sulpho-Cyanides.*

When hydrogen sulphide is passed into a dilute ammoniacal copper solution a black precipitate of copper sulphide or a brownish black coloration is imparted to the solution, depending upon the amount of copper present. A cyanide in ammoniacal solution will bleach such a suspension or coloration. By this bleaching a cyanide can be detected. By the amount of standard copper solution bleached an approximate determination of cyanides can be made in the presence of ferri- and sulpho-cyanides. Ferro-cyanides interfere with estimation, but not detection.

ALBERT P. MATTHEWS: *A Method for Determining the Number of Valences in Molecules.*

O. L. BARNEBEY: *The Permanganate Determination of Iron in the Presence of Chlorides.*

The Reinhardt-Zimmerman method for the determination of iron gives the correct result. Sulphuric acid with manganese sulphate, strong solutions of certain sulphates, certain phosphates with phosphoric acid and cerium sulphate with sulphuric acid can be substituted for the usual "manganese solution" employed to prevent the action of hydrochloric acid during titration. Theories proposed for the explanation of the rôle of these "preventive solutions" are discussed.

HERBERT N. MCCOY: *The Periods of Transformation of Uranium and Thorium.*

ARDEN R. JOHNSON: *A Theory of the Origin and Continuance of Optical Activity in Nature without the Assumption of an Asymmetric Form of Energy or "Vital Force."*

JAMES E. EGAN and CLARENCE W. BALKE: *Atomic Weight of Yttrium.*

W. E. RUDER: *The Intergranular Cement in Metals.*

An investigation is made of the "cement" material between the grains of an iron-silicon alloy of about 4 per cent. Si content. It was found that this material gave exceedingly large grains under the proper conditions of anneal. These grains were separated in two ways: (1) by heating to near the melting point in H and (2) by electrolysis in a solution of  $K_2Cr_2O_7$  (as anode). The first process merely weakens the grain boundaries, which are again reverted to their original strength by firing in a diluted hydrocarbon atmosphere; the second process causes the grain to actually fall apart. From these experiments it is held that the great strength of the intergranular boundaries is due to the presence of certain foreign materials, and not alone to the grain substance in the amorphous phase.

WILLIAM D. HARKINS, H. M. PAINE and R. D. MULLINIX: *The Intermediate Ion Hypotheses and the Solubility of Salts of Higher Types.* (Lantern.)

STUART J. BATES: *The Significance of the Exponent in Storch's Equation.*

For di-ionic electrolytes the exponent in Storch's equation,  $C_i^n/C_u = K$ , has the significance

$$n = 2 \frac{d\pi_i / dC_i}{dC_u}$$

where  $C_i$  and  $\pi_i$  are the concentration and the osmotic pressure, respectively, of the ions and  $C_u$  and  $\pi_u$  those of the undissociated molecules. From freezing point and conductance data it is possible to calculate the osmotic pressure of the ions and also that of the undissociated molecule as a function of the concentration. For KCl from 0.05 N to 0.5 N the osmotic pressure of the ions is 4 to 5 per cent. less than that calculated from

the gas laws, while that for the undissociated molecules is 30 to 45 per cent. greater.

STUART J. BATES: *The Calculation of Equivalent Conductance at Infinite Dilutions.*

A mathematical analysis of the methods employed by Kohlrausch and by Noyes for calculating the equivalent conductance at infinite dilution ( $\Lambda_0$ ) shows that these assume that the expression for the "ionization constant"  $(C\gamma)^2/(1-\gamma)C$  becomes zero at zero concentration. A method is developed based upon a consideration of the exponent in Storch's equation (cf. above abstract) which sets limits between which the value of  $\Lambda_0$  must lie. A graphic empirical method for determining  $\Lambda_0$  values was also developed. In general the values thus obtained lie within, while those calculated by Kohlrausch lie without the theoretical limits. The final adjusted  $\Lambda_0$  values are smaller than those generally employed, for univalent salts by about 0.4 per cent., for bivalent salts about 0.7 per cent. and for trivalent salts about 1.7 per cent.

HARRY N. HOLMES: *Electrostenolysis.*

ARDEN R. JOHNSON and B. W. HAMMAR: *Design for Specific Heat Apparatus (Electrothermal).*

J. CULVER HARTZELL: *The Relation of Geochemistry to Proposed Standard Types of Potable Waters.*

The author considered the geochemistry of waters and distinguished between voluntary or esthetic tolerance and involuntary or human system tolerance. He also considered bacterial count and put emphasis on *B. coli*. Comparative tables from the sanitary and geochemical standpoints were given. The author recognizes the impracticability of standard types of potable waters for universal application; but is strongly impressed with the practicability and necessity of regional standard types to which all municipalities could and should bring their domestic and industrial supplies. Cincinnati, New Orleans and Fargo were cited; the latter showing the most striking results from a most difficult water. Regional types of standard waters were proposed.

J. W. TURRENTINE: *The Structure of the Trinitride Radical.*

R. H. BROWNLEE and R. H. UHLINGER: *Demonstration of the Zeiss Gas Interferometer for the Estimation of Minute Traces of Gases.*

JOEL H. HILDEBRAND: *The Constitution of Certain Liquid Amalgams.*

The formula given in a previous publication for the E.M.F. of liquid amalgam concentration cells was integrated exactly and applied to those amalgams which have thus far been investigated with sufficient accuracy, with the following results:

1. The results of E.M.F. and vapor pressure measurements with zinc amalgams are shown to be in very good agreement. In the light of the vapor-pressure law this is shown to indicate that in these amalgams the zinc exists uncombined with the mercury but associated according to the equation

The equilibrium constant of this reaction, and accordingly the degree of association at different dilutions, is given, and shown to be in excellent agreement with the measurements of E.M.F. and its temperature coefficient.

2. With lead and tin amalgams the same formula relating E.M.F. with constitution as was deduced for zinc is shown to apply, but with a different constant corresponding to a much greater degree of association.

3. The measurements on thallium amalgams are shown to correspond to the formula derived for the cases where combination exists between the solute and the mercury. The compound indicated in this case is  $\text{TIHg}_2$ , which gives evidence of breaking up into some simpler compound, probably  $\text{TIHg}$ , in the more concentrated amalgams.

4. Indium amalgams, on applying the same formula, seem to contain  $\text{InHg}_2$ , breaking down into some simpler compound in the more concentrated amalgams.

5. Cadmium amalgams seem to contain both free Cd and the compound  $\text{CdHg}$ , in proportions depending on the law of mass action. The E.M.F. formula is derived for this case and shown to give the observed values of E.M.F. very closely. The per cent. of the cadmium as  $\text{CdHg}$  is calculated. In the most dilute amalgams two thirds of the cadmium is present as  $\text{CdHg}$ .

The validity of the formula is discussed and its value is pointed out in determining the constitution of metallic solutions and as a means of investigating the present unknown factors influencing the vapor pressure of solutions.

ALBERT D. BROKAW: *The Precipitation of Gold by Manganous Salts.*

Ordinary solutions of gold chloride are rather strongly acid, and from such solutions manganous salts do not precipitate gold even when high con-

centrations are used and the solutions kept boiling for some little time. When the acidity is sufficiently reduced manganese dioxide and gold are precipitated simultaneously, probably according to some such equation as follows:

A suggested explanation is that minute amounts of  $\text{MnCl}_4$  are formed and this substance hydrolyzes when the acidity falls below a certain concentration, giving a precipitation of hydrated manganese dioxide. In more acid solution the acidity suppresses hydrolysis and no reaction takes place.

HANS MANNHARDT: *Tetravalent (?) Nitrogen and Di-Valent (?) Chlorine.*

H. V. TARTAR: *On the Reaction of Sulphur with Potassium Hydroxid in Aqueous Solutions.*

Methods have been worked out in connection with some investigations on the lime-sulphur spray which enable one to ascertain the primary reaction taking place between sulphur and any of the hydroxids of the alkali metals in aqueous solution. Experiments were tried using sulphur and potassium hydroxid in different amounts and in solutions of varying concentration. The results show that the primary reaction of sulphur with potassium hydroxide in aqueous solution is as represented by the following equation:

FRITZ FRIEDRICHS: *Binary Systems. I. Hydrazine, Ammonia.*

In this research, which constitutes the first chapter of an extended investigation of the nature of supplementary valence, the relation of ammonia to hydrazine, the next member of the hydro-nitrogen series, has been studied.

A dilatometric study of the purest hydrazine (shown by analysis to contain 100 per cent.  $\text{N}_2\text{H}_4$  and subsequently distilled twice in vacuo over pure barium oxide directly into the dilatometer) showed a unary melting point of  $+3.3^\circ$ , indicating a very high degree of purity. This pure hydrazine forms no compounds with anhydrous ammonia. The presence of the slightest trace of water, however, leads to the formation of mixed crystals. The complete pressure, temperature, concentration diagram of this system was investigated. The three-phase surface shows a pressure maximum of 630 mm. at  $-19^\circ$ , the solubility line a eutectic at  $-81^\circ$  and a concentration of 85 per cent.  $\text{NH}_3$ .

FRITZ FRIEDRICHS: *Binary Systems. II. Ammonium Trinitride, Ammonia.*

Ammonium trinitride forms with ammonia three compounds containing, respectively, 1, 2 and 4 molecules of ammonia. All of these ammonates show metastable melting points. The inversion point of the diammonate into saturated solution of the anammonous salt is at  $-8.5^\circ$ , that of the tetrammonate into saturated solution of the diammonate is at  $-71^\circ$ , and the eutectic is at  $-87^\circ$  with a concentration of 75 per cent.  $\text{NH}_3$ . The remarkable circumstance that the first two of these ammonates  $\text{NH}_4\text{N}_3 \cdot \text{NH}_3$  and  $\text{NH}_4\text{N}_3 \cdot 2\text{NH}_3$  were never observed to exist together seems to point toward a tautomerism of hydronitric acid. It is not impossible then that the compound may under certain conditions have the older ring formula and under others the chain formula independently suggested by Angeli, Thiele and Turrentine.

FRITZ FRIEDRICHS: *Binary Systems. III. Ammonium Bromide, Ammonia.*

In extension of the work of Roozeboom, who studied a limited portion of this system, ammonates containing, respectively, 1, 3, 6, 9 and 18 molecules of ammonia were shown to exist and the boundaries of their fields were established. All of the three ammonates with the exception of the tri- and the octodecammonate possess metastable melting points. The stable melting points of the two just named were found at  $+9.5^\circ$  and  $-79^\circ$ , respectively. Inversion points were found for the transition of  $\text{NH}_4\text{Br} \cdot \text{NH}_3$  into saturated solution of anammonous salt at  $+36^\circ$ , of  $\text{NH}_4\text{Br} \cdot 3\text{NH}_3$  into saturated solution of  $\text{NH}_4\text{Br} \cdot \text{NH}_3$  at  $+6.5^\circ$ , of  $\text{NH}_4\text{Br} \cdot 6\text{NH}_3$  into saturated solution of  $\text{NH}_4\text{Br} \cdot 3\text{NH}_3$  at  $-69.5^\circ$ , of  $\text{NH}_4\text{Br} \cdot 9\text{NH}_3$  into saturated solution of  $\text{NH}_4\text{Br} \cdot 6\text{NH}_3$  at  $-72^\circ$ . The zone of the saturated solution of the triammonate shows a pressure maximum of 1,600 mm. at  $+4^\circ$ .

As may be seen from the foregoing examples the ammonates are entirely analogous with the hydrates contrary to the recently expressed opinion of Fritz Ephraim (*Zeitschr. phys. Ch.*, 81: 539-542, 1913), who on the basis of an investigation upon the ammonates of certain metallic salts (all of which happened to be insoluble in liquid ammonia) believed that he had discovered a fundamental difference between ammonates and hydrates, since the former apparently showed no inversion points or definite fields of existence.

CHARLES JAMES and E. H. HOLDEN: *Sulphates of Yttrium.*

W. A. NOYES: *Nitro-Nitrogen Trichloride an Electromer of Ammono-Nitrogen Trichloride.*

Ordinary, or ammono-nitrogen trichloride hydrolyzes to ammonia and water. An attempt is being made to secure nitro-nitrogen trichloride, which should hydrolyze normally to nitrous acid and water. To prepare the compound a mixture of nitrosyl chloride,  $\text{NOCl}$ , and phosphorus pentachloride is passed through a porcelain tube heated to  $1000^\circ$ - $1200^\circ$  and containing a little platinum. A mixture of gases which can be condensed with a freezing mixture or by cooling with liquid air is obtained. The analyses indicate the presence of a trace of phosphorus oxychloride, a small amount of silicon tetrachloride, nitrosyl chloride, free chlorine and, in some cases, about ten per cent. of nitro-nitrogen trichloride. C. L. PARSONS,

Secretary

## SOCIETIES AND ACADEMIES

### THE AMERICAN PHILOSOPHICAL SOCIETY

MR. HERBERT E. IVES read a paper before the society on April 4, 1913, on "Illuminants—Present and Future." Modern illuminants are interesting as applications of radiation laws and the science of spectroscopy. The earlier illuminants, such as oil, the candle, the gas flame, the carbon filament electric lamp, are approximations to black-body radiation. Increased efficiency is with these dependent on the attainment of very high temperatures. More recent illuminants possess higher efficiency owing to selective radiation, in accordance with Kirchhoff's law for selectively reflecting or transmitting bodies. Thereby their radiation is relatively more intense in the visible spectrum. This is the case in the Welsbach mantle and the tungsten filament. Another class of selective radiation is met in non-temperature or luminescent sources, where isolated spectrum lines or bands are the source of the light. The mercury vapor lamp falls in this class. The illuminants of the future will be marked by greater efficiency, which may be attained through selective radiation. Whether this will be brought about by the use of gaseous energy or electrical, or through little understood chemical processes such as the firefly exemplifies, is of course as yet unknown. Calculations show that if there were none of the present enormous losses in transforming the energy of coal into light something like 1,200 times as much light could be obtained for the same consumption.

NEW SERIES  
VOL. XXXVII. No. 958

FRIDAY, MAY 9, 1913

SINGLE COPIES, 15 Cts.  
ANNUAL SUBSCRIPTION, \$5.00

## 4th EDITION REVISED ALLEN'S 4th EDITION REVISED

### COMMERCIAL ORGANIC ANALYSIS

EIGHT OCTAVO VOLUMES

EACH VOLUME \$5.00 NET, PREPAID

#### CONTENTS

##### VOL. I

Alcohols; Malt and Malt Liquors; Wines and Potable Spirits; Yeasts; Neutral Alcohol Derivatives; Sugars; Starch and Its Isomers; Paper and Paper-making Materials; Acid Derivatives of Alcohol. 86 Illus., octavo, x + 576 pages.

##### VOL. II

Fixed Oils; Fats and Waxes; Special Characters and Modes in Examining Fats; Oils and Waxes; Butter Fat; Lard; Linseed Oil; Higher Fatty Acids; Soap; Glycerol; Cholesterols; Wool-fat; Cloth Oils. 14 Illust., octavo, x + 520 pages.

##### VOL. III

Hydrocarbons; Naphthalene and its Derivatives; Bitumens; Aromatic Acids; Gallic Acid and its Allies; Phthalic Acid and the Phthaleins; Explosives. 26 Illus., Octavo, x + 637 pages.

##### VOL. IV

Resins; Essential Oils; Hydrocarbons and Ketones of Essential Oils; Caoutchouc and Guttapercha; Special Characters of Individual Oils and Terpenoid Essential Oils; and Tables of Essential Oils. 77 Illus., octavo, x + 466 pages.

## Special Terms

All the volumes now ready (Vols. I to VII) will be forwarded, carriage prepaid, upon receipt of an initial payment of but \$15.00 with the order. The balance may be paid in monthly instalments of \$5.00, thus extending the time when payments must be completed to 4 months from date of the invoice. When the eighth or last volume is published, it will be sent at once carriage prepaid, and the payment for it may be made thirty days afterwards.

This is an unusual opportunity to secure the complete set of this important work. Upon application to the publishers, special terms will also be made to those who already have some of the volumes now published.

Vol. VIII is now on the press and will be issued during the summer.

#### CONTENTS

##### VOL. V

Tannins; Dyes; Colouring Matters; Leathers; Diphenylmethane and Colouring Matters; Colouring Matters of Natural Origin; Analysis of Colouring Matters; Inks; Carbon Papers; Typewriter Ribbons, etc.; Colouring Matters in Food. 6 Illus., octavo, ix + 704 pages.

##### VOL. VI

Amines and Hydrazines; Aniline and its Allies; Other Bases from Tar; Alkaloids; Volatile Bases; Nicotine and Tobacco Products; Acenitric Bases and Atropine; Coca Alkaloids; Opium; Strychnos Alkaloids; Cinchona Alkaloids; Berberine; Caffeine; Cocoa and Chocolate. Octavo, ix + 726 pages.

##### VOL. VII

Vegetable Alkaloids; Non-Basic Vegetable Bitter Principles; Animal Bases; Animal Acids; Cyanogen and its Derivatives; Non-Glucosidal Bitters; Ptomaines; Lactic Acid. Octavo, ix + 563 pages.

##### VOL. VIII

Proteins and Albuminous Principles; Proteins of Plants; Proteins of Milk; Proteins of Milk Products; Milk; Meat and Meat Products; Proteins of Digestion; Haemoglobin and its Allies; Fibroids and Artificial Silk; Enzymes; Proteins.

The "Greenough Leitz" Binocular Travelling Microscope in Case.

## "GREENOUGH LEITZ" Stereoscopic Image Erecting Microscopes

Embodying a new type of construction, providing greater stability than in all previously existing models.

Rigid adjustments of microscope tubes with Porco Prisms is assured by the placing of rack and pinion independent of such adjustments.

Patented Elastic Prism Mounting in Steel Springs—same as in our Prism Binocular Field Glasses.

Upper part of microscope with prism tubes is removable, for attachment to a special hard rubber foot (with independent rack and pinion coarse adjustment), serving conveniently in examination of large surfaces (Dermatoscope Arrangement.)

Paired objectives mounted on self-centering slides, and can be adjusted relatively to each other. One objective in focussing mount to overcome difference of refraction between the observer's eye.

The "Greenough Leitz" is also made in Folding Form, meeting a long felt demand of those who require this instrument when in the field. Supplied in a convenient sized morocco case.

THE intellectual activity of the world, scientific, literary or emotional, passes alternately through fertile and through barren periods. Each fertile period has its characteristic peculiarities and though any one generation may not be competent to form a just estimate of its powers and effects, it is able to compare the fruits of its own labors with the harvest of its predecessors. You will probably agree with me that our age is distinguished by having disclosed a vast array of facts which take us nearer to the infinitesimal structure of matter and which reach further into the infinite design of the universe, than the boldest flight of imagination could have foreseen half a century ago. But we do not flatter ourselves that the intellect of our time, judged by the power of individuals, is exceptionally great. No doubt, men of commanding genius are still with us, but they are not more numerous or more original than in former times. What then is the peculiarity that has produced such great results? In my opinion what has been accomplished is due in great part to the spread of higher education, which has evolved an army of competent investigators possessing enthusiasm for research which now, for the first time, is led into useful paths by the few great minds, whose powers thus receive a wider range and become more productive. It is in this that our great strength lies.

MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

<sup>1</sup> Address delivered before the National Academy of Sciences on the occasion of the semi-centennial celebration of its foundation.

The functions of an organization devoted to research are to take full advantage of all available mental resources. Intellect can not be artificially created nor can originality be taught, but whatever intellect and originality exist, may be directed into fertile channels, so that those who have the gift of connecting facts shall not fail because the facts are not available.

The advance of science demands that experiment or observation and theoretical discussion should advance in parallel lines. Without organization, one of the teams on whose joint exertions the advance depends is likely to outrun the other. Thus Newton, when he had formulated his law of gravitation, which connects the orbit of the moon with the acceleration of falling bodies, did not publish his discovery for many years, because he could not verify his theory as closely as he desired. It was only after the French Academy had accurately measured an arc of meridian and had discovered a substantial error in previous measurements that Newton's law of gravitation could be said to be proved. In this case theory had gone ahead of observation; but examples of the opposite kind will not be wanting so long as we have observers concerned entirely with the accumulation of data, content to leave discussion to the dim future. It is one of the objects of organizing science to bring the two factors to bear on each other.

International cooperation in research is necessary because scientific inquiries can not be divided into compartments limited by political boundaries. The very language which we use to express our thoughts is tied down by conventions, some of which we have absorbed as students, but which in the case of new branches of learning have formally to be agreed upon. Our measurements—and all accurate science depends on measurements—have to be ex-

pressed in units, and how are these units to be fixed except by agreement? While this will be acknowledged by every one, it is not equally recognized how much our present refinements in scientific research depend on organized efforts. Whether these efforts should be concentrated in a single laboratory or confined within one political unit or carried out by the combined scientific community of the world, mainly depends on the nature of the problem.

It is not my purpose to trace in detail the history of international problems and international organizations; but, rather, to show the great variety of problems in which useful results have already been achieved by international cooperation, and to bring the lessons of the past years to bear on the future.

I divide international cooperation into three categories:

1. Agreement on standards and units of measurement.
2. The distribution of work bearing on the same problem, between different nations, for the purpose of economizing time and expenditure.
3. The investigation of problems which can not be solved unless observations made with identical or similar instruments are obtained from different parts of the world and the records published in a homogeneous form.

I think all are agreed as to the question of units and I need not detain you by giving you an account of the various international conferences which have been held and agreements which have been arrived at on these matters.

As regards problems of the second category, they are those which deal mainly with the cosmos, as a whole, because their solution depends so much on the collection of statistics which exceeds the powers of

individuals or even of single nations. A few examples may illustrate what has already been accomplished. First, and foremost, we have the great star catalogue, initiated at an international congress twenty-five years ago, when eighteen observatories combined to divide the work, each taking a number of zones in the heavens.

The importance of this work will be plain to every one, and we must regret that it is still so far from being completed.

As it is not my intention simply to point out the merits of international work, but also to point out its difficulties, a few words may be said which are not intended as criticism, but which may serve to point out the weakness which arises when there is no central authority which lives longer than the single individual can expect to live.

Pioneers will always be found to initiate a work, but in time they die or retire from office; others take their places, and if these become more interested in fresh problems, the work suffers unless it is effectively impressed on their attention by some permanent body. Where to find such a central body, whose main functions would be to endow an undertaking with sufficient inertia to carry it over periods in which the work may seem to be a drudgery, is a matter which deserves careful consideration.

The completion of the "Star Catalogue," which has given rise to these remarks, is only the beginning of an even greater piece of work. When we have determined the positions and magnitude of stars at any one time, we have only taken the first step towards solving the main problem, and must proceed to measure the proper motions, the parallaxes, and also map the spectra. This work is so vast that all hope to accomplish it within reasonable limits is difficult and has to be abandoned

unless our statistical ambitions are lowered, and instead of taking the complete sphere of the heavens we select restricted but typical areas for detailed examination. This has been done on the initiative of Professor Kapteyn, who has secured a sufficient number of voluntary associates who are now carrying out a combined undertaking which has already yielded results of the greatest importance, and you will hear something more of this work from his own lips.

Now the essence of work of this kind consists in shortening the time required to accomplish an extensive task by dividing it among a number of persons. If the work is purely statistical it may be complete in itself, and the published records become then available to any one who requires them. In other cases, the observations may have to be collected by a central authority and treated by recognized methods of statistics or analysis before they become useful to the scientific public. While it is generally the observational portion of the work that is subdivided and the discussion that is centralized, the reverse is the case in the proposal made by Professor Pickering—that one central observatory in a favorable position should furnish photographs in sufficient numbers and distribute them among astronomers all over the world, to be measured and discussed.

Finally, a great undertaking of quite a different character—the "International Catalogue of Scientific Literature"—must be classed in the same category. This catalogue has arisen out of a desire to classify the scientific literature of the world, so as to enable any one who desires to study a certain subject to find out quickly all previous researches relating to it. Practically all nations in which scientific work is carried out have united, each

collecting its own data and forwarding it to the central bureau in London.

I can not pass away from this type of international cooperation without expressing regret that a proposal which was made by the late Professor Simon Newcomb has not been adopted hitherto. When the first program of the Carnegie Institution of Washington was being discussed, he proposed that there should be some central computing bureau established at one place where accumulated data of observation, which required scientific treatment, could be discussed and treated in that way. The number of instances which have come to my own notice within the last few years, in which the existence of such a bureau would have been of the greatest assistance to the progress of science is considerable; and I feel very little doubt that others have also felt the want.

The problems which fall into the third category are mainly those belonging to the important and much neglected subject of geophysics. The time is past when we could separate the physics of the laboratory from that of the earth, and that again from the physics of the universe. The experimenter who now studies the structure of the atom must keep an eye on the sun and stars in order to detect whether celestial observations destroy his theories or give them strength.

Atmospheric electricity and terrestrial magnetism, treated too long as isolated phenomena may give us hints on hitherto unknown properties of matter. A meteorologist, finding out at last that space has three dimensions, and that the motion of air is governed by the laws of mechanics, has converted what hitherto has been a sport into a science.

Before enumerating the international associations which are dealing with these problems of geophysics, let us say a few words as to the problems themselves.

We have, first, to study the shape of the earth and the variations in the gravitational forces which are observed on its surface. We have further to take account of the secular variations of level and of the more or less violent disturbances which accompany earthquakes and earth tremors. By comparing the indications of instruments placed in different localities, we can deduce the rate of propagation over the earth and through the earth of the seismic waves. This yields us important information on the physical properties or material composing the interior of the earth. The cause of terrestrial magnetism is at present unknown, and we have no means at our disposal to attack the problem directly, but the study of the diurnal and secular variations may give us a clue, and deserves our closest attention.

In a similar way, the study of the higher atmosphere and of the high electric conductivity which the air is now known to possess at heights which we can not reach, is also a subject which can only be studied by combined efforts. How are these questions dealt with at present?

We have, first, an International Association of Geodesics, which is an exceedingly efficient body, with a bureau at Potsdam, under Professor Helmert. That association is successful, perhaps, partly because its work has been facilitated in that it had to build on virgin soil. Nothing had been done, to a very great extent at any rate, internationally before that association came into being. On the other hand, we have the International Association of Seismology, a related subject, which was only founded at the beginning of the present century, with a central bureau at Strassburg. This association had to overcome more serious difficulties. It entered into the field when there was already a less expensive organization in existence, which had been originated by Professor Milne

and was directed by a committee of the British Association. The question of instruments also presented peculiar difficulties, which it is hoped may soon be overcome.

As regards terrestrial magnetism, I have only a few words to say.

Through the magnificent efforts of the Carnegie Institution of Washington, we are at last likely to have a satisfactory magnetic survey of the world, but important as the results obtained by Professor Bauer in the *Carnegie* will prove to be, they will have to be supplemented by systematic observations of the variations of the magnetic forces at a number of fixed stations. Many such stations are in existence, though they are very irregularly distributed over the surface of the earth.

In this subject, almost more than in any other, an international agreement on the manner in which the records are to be treated and published is essential, and it is much to be regretted that the attempts that have been made to reach such agreements have not met with greater success. There are, no doubt, peculiar difficulties due to differences in the organization of the magnetic services.

Methods have developed independently in different countries, and there is a natural but regrettable reluctance to alter an instrumental detail or a peculiarity in treating the observation until the necessity of the change has been demonstrated. But that can never be done, because practically all methods are equally good. What is bad is that they differ. Almost any one of these methods could be adopted with advantage anywhere; so that a discussion of which of the methods is better than the other is futile. The first essential then is that in every place on earth the same methods should be adopted, because the least difference in them may cause impor-

tant errors in the deductions when they come to be compared with each other.

The only body which at present deals systematically with the records of terrestrial magnetism is a sub-committee of the Meeting of Directors of Meteorological Observations. The Directors of Meteorological Observations meeting at intervals have appointed a certain number of sub-committees dealing with a certain number of subjects. Some of these overlap other associations already. So that, for example, the question of solar radiation falls partly under that sub-committee of the directors of meteorological observations and also under the International Solar Union, a union which has been founded by your foreign secretary, Professor Hale.

The present international organizations differ considerably in the manner in which their expenditure is provided for. The International Geodetic Association, the Association of Seismology and the International Bureau of Standards are directly supported by the governments, the contributions depending upon the population of each country and amounting, for the larger ones to—I need not give you the figures now. They are of no particular interest.

The "International Catalogue of Scientific Literature" is a very costly undertaking, and that is provided for by each country guaranteeing the sale of a certain number of copies; a capital fund having been paid to start the organization by the Royal Society of London.

In the case of the great "Star Catalogue," each observatory is responsible for its own expenditure. The four French observatories have received government contributions amounting together to over \$500,000. In England a much smaller sum has been given, and in other countries the

work has languished a good deal because sufficient funds were not available.

The Solar Union has no funds whatsoever and is even unable to pay for its own publications. Sufficient has been said to show how wide a range is already covered by international research. Further extensions of the work are constantly being called for, and we are brought face to face with the problem that separate associations can not be multiplied indefinitely without introducing difficulties which, as their number increases, endanger the objects which they are intended to serve. Apart from the overlapping of interests and questions of finance, the time spent in correspondence and administration is already serious. The nature of the problems suitable to be dealt with by international efforts is such that the same persons are generally interested in several of them, and the meetings succeed each other so rapidly as to become a serious tax on the time of those who attend them and some who used to look with favor on international work are beginning to be frightened.

Perhaps we may look forward to some arrangement to combine the meetings of the different associations in the manner of the different sections of the British Association, for instance. But this would require some central authority to act as a bond between the bodies which at present are separate and independent.

Economy of working, both financial and administrative, points in the same direction, and we are driven to the conclusion—and that, I think, I should like to make the moral of this paper—that the present policy of establishing a separate association for each new extension of international work should be reconsidered and an effort made to economize time in working and administration by some larger scheme, including the various separate interna-

tional institutions on related and similar subjects.

Realizing that it is necessary to take some action in this direction, yet perhaps not understanding correctly why the action is necessary, an ambitious undertaking has been evolved in Belgium, where it is proposed to erect an office uniting international associations, whatever their object or character may be. The promoters have drawn up their statutes, one general congress has already been held, and another is now being organized. No success can, however, be expected from a scheme launched by a self-constituted and irresponsible body, unless its program commands general respect.

Is this the case in the present instance?

I do not know whether you realize the number of associations which exist. I shall not call them "international associations," but associations which call themselves international. The number to be united in this Belgium scheme is 279, and each of them, if I understand the proposals correctly, may have an office in a large building to be erected for the purpose. If you read through the list of these associations, I do not know what your feeling would be, but I can describe to you what mine has been; and it is exactly like that which I should have if I were to enter a museum, and find, side by side, the Venus of Milo, a living tiger, a collection of rare manuscripts and sanitary appliances. You will be interested to hear that, amongst the institutions which are to be provided for in this building, is the International Bureau of American Republics; but it is also intended to include "The International Congress for Providing Cheap Lodgings." Any one who enters the building and tries to find the particular room to which he wants to go has to ask the man in charge.

You can imagine this kind of a conversation taking place:

Is this the International Union of Friends of Young Girls?

No, but it is the International Congress of Commercial Travelers.

The architect, no doubt, will do his best to group together associations relating to the same subjects, and it would be interesting to pass through the corridors devoted to all the religious and irreligious societies that take the name of "international." If a humorist were to exchange the name plates over the doors, the mathematician who has traveled all the way from Australia to attend the "International Congress for Promoting the Study of Quaternions" might find himself in the room reserved for the "International Union of Woman Suffrage," and a member of the Association of Seismology might be mixed up with the "Association to Prevent the Abuse of Alcohol."

I do not like to throw ridicule on what is obviously a well-meant effort, but however much our sympathy may extend to each of these objects separately, no good purpose is served by inventing a connecting link between incommensurate objects, such as solar research and the proper observance of Sundays.

Our work is sufficiently difficult, if we confine ourselves to scientific methods. It nevertheless remains true that it is desirable to establish some central authority which can act as a connecting link between different associations. What should its functions be? It is the essence of all international combinations that they depend entirely on moral force and have no power to impose their decisions. A central authority must therefore be content with offering advice, with the conviction that, if the advice is sound, it will be accepted.

Though the existing associations would

tolerate no interference with their independence, they would doubtless consider with care any suggestions made to them in the interests of science by an authoritative body. Our problem is therefore to find an authority of sufficient eminence to be generally looked upon with confidence and who could also act as adviser to different governments when they are asked to financially support some fresh undertaking. That is one of the most serious difficulties of the present time. There is a new international undertaking proposed almost every year, and application is made to the different governments for support and money. What is the government to do? To whom is the government to go for advice whether such an undertaking is worthy of support or not? My solution of that question is this: In the International Association of Academies we possess indeed a body fulfilling all the requirements of such a central authority, provided the individual academies constituting the association are willing to undertake the task. The Association of Academies was founded at a conference held at Wiesbaden on October 9 and 10, 1899, the National Academy of the United States being represented by Professors Newcomb and Bowditch. The paragraph of its statutes which were adopted at a meeting held in Paris in 1901 relating to the functions of the association runs as follows:

The object of the association is to prepare and promote scientific work of general interest which has been submitted to it by one of the associated academies, and to facilitate in a general manner scientific intercourse between different nations.

From its origin the association claimed an advisory voice in new international undertakings, and at the meeting held in London in 1904 the following resolution was passed with one dissenting voice:

That the initiation of any new international organization to be maintained by subventions from

different states demands careful previous examination into the value and objects of such organizations, and that it is desirable that proposals to establish such organization should be considered by the International Association of Academies before definite action is taken.

After a period of activity ranging over about twelve years it may be useful to review the work which has been accomplished, but I shall confine myself to the record of its section of science, remarking only that the section of letters has also much important work in hand.

The powers of the association are purely advisory; it has no funds at its disposal and for this reason alone is unable to initiate or support any scientific enterprise unless the individual academies provide the expenditure, as is being done, for instance, in the publication of Leibnitz's works, which has been undertaken by the academies of Berlin and Paris jointly. A complete map of the moon with its features named according to an agreed scheme is in process of preparation and is welcomed by students of the lunar surface. Among the subjects which have been treated, the excellent work done by an autonomous committee appointed to investigate the functions of the brain should also be referred to; and there are a number of various committees which have done good work.

In many cases the association has been called upon to express a favorable opinion on the importance of some international scheme which is independently being pressed upon the consideration of one or more governments. To deliver a platonie blessing is so gratifying a task that applications for it are not perhaps always scrutinized with sufficient care, though I admit that it is better to support a doubtful enterprise than to risk stopping a good one.

The association has been most successful

when it has used its influence to press important scientific objects on the attention of their governments. It is in part at any rate due to their recommendation that money was found for the measurement of the great arc of meridian, which, covering 105 degrees, stretches through Russia and Roumania and continues through Asia Minor and western Africa, to the Cape of Good Hope. This is a continuous arc of meridian reaching from the north of Russia to the Cape of Good Hope in which a number of governments—the British government, the German government, the Russian government and the Turkish government—are involved, which is in process already, and is really nearing completion.

It has become the practise during recent years that international organizations established independently place themselves under the protection of the Association of Academies, to which they report periodically. Though the academies exercise no control over such bodies they stand to them as a reserve power willing to help when required.

In all these respects the association has fulfilled the intention of its founders, but has it left its mark to any appreciable extent on the progress of science? Without wishing to underrate the good that this body has done in the past I do not think I stand alone in hoping for a wider activity in the future, and I doubt whether it will long maintain its vitality unless it extends its ambitions as it passes from the age of youth to that of manhood. This is a critical period in its history, and much will depend on the policy it will adopt on a question which may still be kept in abeyance for a short time, but which will have to be faced before long.

An international organization which has no central office and is not domiciled in

any country is not a legally constituted body. It possesses no property. It can not accept gifts or legacies. The question has been repeatedly raised whether it is desirable to remove this restriction and to establish the association on a legal foundation. For this purpose it would have to place itself under the laws of some one country, and the selection of that country complicates the decision on the main issue, as national consideration and perhaps to some extent national jealousies have to be taken into account.

To clear our minds, let us separate the two issues, that of the power to hold property and that of a permanent domicile. Each academy knows from its own experience that though individual research may often be carried out at a small cost an organized investigation demands funds which become considerable when its range is wide. It is therefore just the type of work that an international organization is best fitted to undertake which demands the greatest amount of assistance.

The question to be faced is this:

Shall our International Association be forever content to exercise a purely platonic patronage, or shall it take an active part in promoting research? If it chooses the latter course it seems to me to be indispensable that it should have funds at its disposal.

I advocate the bolder policy on two grounds: Firstly, international research is most logically administered and paid for by international funds, and, secondly, it seems to me that a purely moral support can not, in the long run, remain effective. The existing special associations, as I have already stated, must retain their complete independence, and it is not likely that it will ever be desirable that the Association of Academies should undertake any work

in which financial support is expected to extend over a considerable period; but when promising enterprises are in their experimental stages, funds are often most urgently required and most difficult to obtain.

It is here that an international body, having an independent income, could most efficiently step in to support meritorious enterprises during the few critical years until they can be either established on a permanent basis or have completed their work.

I recognize, of course, the weight of certain objections which have been raised, but I think we must run the risk all the same, for my experience teaches me that there is seldom any vitality without antagonism; and the main ground of objection is that we are going on so nicely, we never disagree and therefore we had better remain as we are. But after all, our progress is only obtained by those having differences of opinion coming together and adjusting their differences.

Even should the general opinion be against me, and if it were definitely decided that the International Association of Academies should forever maintain its present state of poverty, the establishment of a domicile on a moderate scale will have to be considered as an independent issue. It might be mentioned that in the original proposals of the Berlin Academy, they intended that there should be not only a central bureau but an organ, published monthly or quarterly, giving an account of the work done by any one academy that would interest the other academies.

The policy which the International Association of Academies will adopt on these questions is one of the most vital importance, for not only will the future of international work depend on the course

taken, but the reputation and influence of the academies themselves will, I am convinced, be seriously affected by the decision.

It is with the greatest hesitation and with much diffidence that I now approach the concluding portion of my discourse, for I am oppressed by the fear that my remarks may be taken as an unnecessary interference in the concern of others. But the issue is too serious to let that prevent my expressing an opinion which is based on a deep, and I believe impartial conviction.

The academies, royal societies, or whatever name they are called by, have been founded at different times in accordance with the varying requirements of their countries. They value their historical traditions above everything; some are over two hundred years old, others of recent growth, and their constitutions differ in many respects. But whatever their constitution and their history may be, they must be judged by this same test: Do they fulfill their obligations, which for all of them, I take it, are those defined in the charter of the Royal Society as "The promotion of natural knowledge." Do they embody in themselves the promotive power of the scientific efforts of their country, or have they fallen a prey to the dangers, which more especially beset the older institutions, of crystallizing into an aristocracy of science, recruited from those who in the natural course of growing maturity are ceasing to be active workers and constitute themselves to be the judges of the work of others? The dead weight of such a society brought to bear discretely on the exuberance of youth may have its uses, but it remains a dead weight just the same. It should act as a brake on a too fanciful imagination, but it can take no share in any real progress. If the academies are to

fit themselves for the formation of a really strong and fruit-bearing association, they must be bodies which, animated, as all of them now are, by the highest and noblest ideals, strive at the same time to represent what is best and most progressive in the scientific life within their range of influence.

Each country must solve its own difficulties, but in addressing your national academy which, though it holds to-day its first jubilee, may still be called youthful, I may be forgiven if I remind you that, while the older institutions may offer you much that deserves to be admired and perhaps be imitated, you must not mistake the signs of gray hairs for the stamp of an enviable dignity.

This, then, is my final summary. Ours is an age of organization presenting many problems that can not be confined within political boundaries. The demands of science have already called into existence separate international associations, which are efficiently performing their duties. Nevertheless the continued increase of their number is beginning to cause inconvenience and is likely to hamper future developments unless they can be united by some bond intended to coordinate their work. The International Association of Academies stands out as a natural body, fit to act as a central advisory authority. To exercise that authority effectively, the academies must individually recognize their obligations to be truly representative of the most healthy and vigorous portion of the scientific life of their country. It is because I believe in the vitality of the academies and in the power which an increased responsibility will give them to check the danger of stagnation to which ancient and dignified bodies are exposed, that I advocate the extension of their activity and the

more vigorous exercise of the dormant power which resides in the union of the illustrious bodies which together constitute the International Association of Academies.

ARTHUR SCHUSTER

ROYAL SOCIETY OF LONDON

*SIR WILLIAM OSLER'S SILLIMAN  
LECTURES*

SIR WILLIAM OSLER delivered the first of his six lectures on the "Evolution of Modern Medicine" on the Silliman foundation at Yale University on Monday afternoon, April 21. The last lecture was delivered on the 28 ult.

In his first lecture, according to the report in the *Yale Alumni Weekly*, Dr. Osler dealt with the origin of medicine in primitive man and its relation to magic and religion. Certain special practises, such as trephining, were described and illustrated by the lecturer. Egyptian medicine was considered in its three important aspects—magic, the use of animal extracts, and the specialized modes of practise recorded in the famous Ebers, Hearst and Berlin papyri. Divination, particularly by inspection of the liver, astrology and the Hammurabi code, were taken as illustrating the special features of Assyrian and Babylonian medicine. The extension of astrology was traced through Greece and Rome. Among the Hebrews the excellent hygienic regulations were discussed and brief reference was made to the miraculous healing in the New Testament. Dr. Osler showed that the character of ancient medicine may be studied today in China, where charms, enchantments and death-banishing herbs are universally employed.

In the second lecture Professor Osler dealt with the beginnings of science in Greece, dealing first with the nature philosophers of Ionia and south Italy, whose contributions to medicine, while not numerous, were of great importance as influencing the thought of subsequent workers. The physicians of this school were independent of the Osculapian

cult, the growth of which he then sketched as met with at Epidaurus and Cos. The work of Hippocrates was discussed and his fundamental proposition that disease was a natural phenomenon to be studied. The high-ethical character of Greek medicine was illustrated by the famous oath of Hippocrates. The rise of the Alexandrian School and the study of human anatomy was then considered, and the high-water mark of the period was reached in Galen of Pergamus, whose life and work were described.

In the third of his lectures he treated medieval medicine. He traced the stream of Greek medicine through the three channels in the middle ages—the first continuous Greek tradition in south Italy, which found its highest development in the School of Salerno; secondly, through the Byzantine sources; thirdly, through the Arabs, who by the ninth century had had translated for them all of the Greek writers. From the Spanish translators of the thirteenth century, from Salerno, and by the dispersion of learned Greeks with their manuscript after the fall of Constantinople, Greek medicine reached modern Europe. He then traced the growth of the universities of Bologna and Montpellier and their influence upon medicine, particularly the former, where anatomy was first studied. Medicine of the middle ages was a restatement from century to century of the facts and theories of the Greeks, modified here and there by Arabian practise. In Bacon's phase there was much iteration, small addition.

In lecture four Professor Osler dealt with the beginnings of modern medicine as illustrated in the lives and works of three men. Paracelsus represented the spirit of revolt against authority and tradition. His positive contribution to medicine was small in comparison with the stimulus which his antagonism to the older writers aroused in his generation. Vesalius was the first to describe and illustrate with system and accuracy the structure of the human body. He may be said to be the creator of human anatomy as we know it. Professor Harvey Cushing, of Harvard,

showed a collection of first editions of the works of Vesalius, among which was the *Fabrica* of 1543, one of the most sumptuous works ever published. Harvey—the first great student of a function of the body—demonstrated the circulation of the blood in a series of masterly experiments which have been a model for all subsequent workers. In the publication of the “*de Motu Cordis*,” modern physiology may be said to have had its origin.

In lecture five Professor Osler described the steps by which we had obtained our knowledge of the changes wrought in the body by disease—morbid anatomy, the rise of clinical medicine, the introduction of means of physical diagnosis and the development of experimental pathology. The modern study of infectious diseases was traced, the work of Pasteur and of Koch described, and the practical application by Lister of the antiseptic method. The new problems in relation to the internal secretions were discussed, and it was held that the future would be largely concerned with studies in metabolism and clinical chemistry.

In the last lecture the practical application of the knowledge derived from recent researches was considered in relation to some of the more important diseases. The story of malaria was told in full and it was urged that a more active campaign against the disease should be undertaken in the southern states. The victory over yellow fever was retold, and the experience of the Panama Canal Commission was held up as a model showing what efficient organization will do. The building of the canal was made possible by the work of Laveran and of Ross and of Walter Reed and his colleagues. An appeal was made for more efficient control of typhoid fever and for a continuance of the fight against tuberculosis.

---

#### PROFESSOR BOWMAN'S EXPEDITION TO THE CENTRAL ANDES

PROFESSOR ISALAH BOWMAN, of Yale University, sailed from New York on April 26 to conduct a South American expedition under the auspices of the American Geographical Society. His purpose is to complete the investi-

gations he began in 1907 in northern Chile and Bolivia and continued in 1911 in the basin of the Urubamba River, Peru. His work this summer will be in that part of the central Andes lying in Peru, northwestern Argentina, adjacent portions of northern Chile and southwestern Bolivia. Professor Bowman will be accompanied by Mr. H. S. Palmer as geologist and a surveyor.

His field work will chiefly relate to the anthropogeography and the physiography of this region. The investigation of topography, drainage and climate will thus go hand in hand with the distribution and customs of the people. Part of the work will lie in the driest portions of the Puna of Atacama and the adjacent desert of Atacama where villages in isolated situations, vast salt plains and lofty table lands alternate with rugged volcanic masses and snow-capped sierras. It is a little-known region and some of the most interesting parts of it have not yet been studied scientifically. The climatic conditions are of great interest and the possibility exists of securing critical data on past changes of climate since the region lies in the transition zone of the horse latitudes, between the trades and the westerlies. The shifting routes of trade have had remarkable effects on the towns and villages scattered along them, not only in stimulating them to an unnatural degree, but also in sudden decay.

An attempt will be made to cross the Andean Cordillera and the Desert of Atacama along two different parallels where the contrasts in altitude are most marked and thus to study the distribution of people under extreme conditions of physical environment.

The last part of the field season will be spent in investigating the border of the Titicaca Basin and descending the Desaguadero River as far as possible towards Lake Poopó. The elevation of the ancient strand lines of Lake Minchin, which once occupied a part of the Bolivian high plateau, will be determined. The relations of this now vanished lake and Lake Titicaca have never been investigated and the key to the problem will be sought in the outlet of the Titicaca Basin. There, also,

must be sought the key to much of the early history of the Titicaca depression. The Tiahuanaco Valley and its celebrated ruins will be studied in relation to the supposed ancient levels of Lake Titicaca and the limits of food production in the valley to-day.

Professor Bowman's results will be published in preliminary form in the *Bulletin* of the American Geographical Society and in final form in a volume entitled "The Central Andes."

---

GLACIAL EXCURSION OF THE CANADIAN  
GEOLOGICAL CONGRESS

SEVERAL of the excursions, in connection with the twelfth International Geological Congress, held in Canada next summer, will go from Toronto to Vancouver. Then an excursion (CS August 29 to September 22), under the leadership of R. G. McConnell, and with guidance of R. W. Brock, D. D. Cairnes, and W. W. Leach, will traverse the fiords of British Columbia, ascend the Skeena River valley from Prince Rupert to Aldermere by rail, visiting the silver-lead mines and coal mines, and continuing to Skagway by steamer. There will be stops at the copper mines on Portland Canal and the Treadwell gold mine on the Gastineau fiord at Juneau. The excursions will then cross the Canadian Coast Range by the White Pass and Yukon Railway to Whitehorse, stopping at the copper deposits there and the coal mines at Tantalus, descending the Yukon River to Dawson and the Klondike gold field in the driftless interior plateau near latitude 64° north.

After the return to Skagway an excursion, under the direction of Lawrence Martin of the University of Wisconsin, will be made, on a special steamer, to the Malaspina Glacier, Yakutat Bay, and Muir Glacier, where Russell Wright, Reid, Gilbert and Tarr have done world-renowned work. This glacial excursion will last five days, with a possibility of two days more in case of cloudy weather.

The first day will afford an opportunity of seeing the Fairweather and St. Elias Ranges, 16,000 to 18,000 feet high, and covered by

snowfields and glaciers. These ice tongues include the La Perouse, Malaspina and many smaller glaciers. The front of the great piedmont ice sheet of Malaspina Glacier will be followed, affording an opportunity of seeing the tidal ice front of the Guyot lobe west of Yaktse River, the moraine-veneered ice cliff of the Seward lobe at Sitkagi Bluffs, and the forest-covered terminus of the Marvine lobe near Point Manby.

On the second day something will be seen of the eastern border of Malaspina Glacier in Yakutat Bay and the forested terminal moraine of the Yakutat Foreland. Landings will be made in Disenchantment Bay in connection with various glacial phenomena such as the shrub-covered ablation moraine upon the ice of Variegated Glacier, the streams engaged in carrying and depositing outwash gravels, the calving of icebergs from Hubbard and Turner glaciers, the cirque vacated by a fallen glacier, and the beaches, rock benches, sea cliffs and islands which were uplifted from 7 to 47½ feet during the earthquakes of September, 1899.

The third day will be spent on and near the Nunatak Glacier in Russell Fiord. Here the hanging valleys, the till-veneered, overridden outwash gravels, and the tidal, land-ending and cascading glaciers will be visited and studied, as well as the phenomena of glacial erosion in the barren area from which the ice has recently retreated and of fault scarps made during the 1899 earthquake. Some of these scarps are vertical and are 4½ to 8 feet high.

The fourth day will afford an opportunity of seeing the morainic and glacio-fluvial phenomena about the terminus of the Hidden Glacier, which advanced 2 miles between 1906 and 1909, as a result of the earthquake avalanching in 1899 which has subsequently caused 9 ice tongues of Yakutat Bay to move forward. After this landing something will be seen of a fiord with submerged hanging valleys, submarine moraines, buried forests, shorelines depressed in 1899, and the high strand lines of a former glacial lake.

Part of the fifth day will be devoted to

Glacier Bay, where there has been a recession of  $8\frac{1}{2}$  miles at Muir Glacier from 1899 to 1911. A landing will be made in Muir Inlet to see the buried forests, the vertical ablation of over 1,200 feet of ice in 12 years, and many other phenomena. The rapid recession of Grand Pacific Glacier in Reid Inlet at the head of Glacier Bay now places part of this fiord in Canada. The glacier melted back 5,000-7,400 feet in two months during the summer of 1912, as was determined by N. J. Ogilvie of the Canadian Boundary Survey. At the International Boundary there is now dry land and open fiord where the ice was at least 1,750 feet thick as recently as 1894. Sixty miles of Glacier Bay have been opened to the ocean by glacier recession since 1794, making an arm of the sea as long as Hardanger Fiord in Norway.

The National Geographic Society of Washington has made a grant of money to Professor Martin to enable him to make detailed studies at Grand Pacific and Muir Glaciers while the excursion is in the Klondike. He will (a) measure the recession of several ice tongues in Glacier Bay, (b) look for advances of glaciers, (c) study the exhumed forests in relation to former glacial oscillations, and (d) make soundings in Canada's new harbor and other uncharted waters recently vacated by the glaciers, to see the effects of ice sculpture below sea-level.

#### SCIENTIFIC NOTES AND NEWS

A TABLET in honor of Dr. Samuel Pierpont Langley was unveiled in the Smithsonian Institution on May 6. Addresses were made by Dr. Alexander Graham Bell and Dr. John A. Brashear. At the same time Langley medals were awarded to M. Gustave Eiffel and Mr. Glenn H. Curtiss. Later in the afternoon the Aero Club of Washington arranged hydro-aeroplane maneuvers on the grounds of the Army War College in honor of Dr. Langley.

THE Chemical Society, London, will hold a special meeting on May 22, when a lecture in memory of Jacobus Henricus van't Hoff will be delivered by Professor James Walker, F.R.S., of Edinburgh.

DR. JOHN M. CLARKE, New York state geologist and director of the state museum, has been invited by the president and council of the Royal Society of Canada to deliver the annual public address before the society at Ottawa on May 28.

DR. E. F. ROEBER has been elected president of the American Electrochemical Society.

DR. A. E. KENNELLY, of Harvard University, has been elected an honorary corresponding member of the British Association for the Advancement of Science.

PROFESSOR L. J. LANDOUZY, dean of the Paris faculty of medicine, and known by his researches on nervous diseases and tuberculosis, has been elected a member of the Paris Academy of Sciences, in succession to the late M. Teisserenc de Bort.

SECRETARY LANE has announced the selection of Professor Adolph C. Miller, who holds the chair of economics and commerce in the University of California, as first assistant secretary of the interior. Secretary Lane intends to assign to Mr. Miller general supervision of the Bureau of Education and of the national parks; the direction of eleemosynary institutions, such as Howard University and the Government Hospital for the Insane, and the handling of legislative matters in connection with the constructive policies of the department.

DR. KARL KOETSCHAU, director of the Kaiser Friedrich Museum in Berlin, has accepted the directorship of the newly established Central Museum in Dusseldorf.

DR. ALBERT M. REESE, professor of zoology in West Virginia University, sailed on May 5, from San Francisco, on the army transport *Sherman* for Manila, to study the fauna of the Philippines and other regions of the orient, and to make collections for the Smithsonian Institution, from which institution he holds a commission as "collaborator in zoology." He will return to the United States in September.

FORMER PRESIDENT GEORGE E. MACLEAN, of the State University of Iowa, has accepted temporarily the position of specialist in higher

education in the U. S. Bureau of Education. He sailed May 1 for Europe to continue studies of the British universities upon which he will prepare a bulletin somewhat along the lines of his bulletin on "Present Standards of Higher Education in the United States," just issued by the bureau.

THE adjudicators of the Adams Prize of the University of Cambridge report that the two essays submitted to them with the following titles are of distinction: "The Theory of Radiation," by Mr. S. B. McLaren, and "The Fundamental Spectra of Astrophysics," by Dr. J. W. Nicholson, between whom the prize is divided in equal shares.

PROFESSOR C. J. KEYSER, of Columbia University, delivered the annual lecture before the Minnesota chapter of the Society of the Sigma Xi on April 24. The subject of his lecture was "Concerning the Figure and the Dimensions of the Universe of Space."

PROFESSOR WILLIAM MARSHALL, of the department of mathematics, addressed the Purdue Chapter of Sigma Xi on "The Theory of Relativity and the New Mechanics," on April 23.

PROFESSOR BERNHARD KRÖNIG, professor of obstetrics at Freiburg, has accepted an invitation to lecture on Röntgen and radium therapy for the American surgical society, Chicago.

PROFESSOR WILLIAM MORRIS FONTAINE, for thirty-one years professor of natural history and geology in the University of Virginia, distinguished for his researches in paleobotany, died suddenly of heart failure about one o'clock on April 30. Professor Fontaine was in his seventy-eighth year. After eminent service for forty years as teacher and investigator, Professor Fontaine retired in September, 1910, on the Carnegie Foundation.

PROFESSOR A. C. ELLIOTT, professor of engineering at the University College of South Wales and Monmouthshire, has died at the age of fifty-two years.

DR. ERNST GEORG RAVENSTEIN, the distin-

guished geographer and cartographer, has died at the age of seventy-nine years.

THE U. S. Civil Service Commission announces an examination on June 2, 1913, for associate physicists, qualified in mechanical or civil engineering and in electrical engineering, to fill vacancies in these positions in the Bureau of Standards, at Washington, D. C., at salaries ranging from \$2,000 to \$2,700 a year, the salaries actually paid depending upon the qualifications of those selected.

THE British Board of Agriculture and Fisheries proposes to award in October next twelve research scholarships in agricultural science, of the annual value of £150 and tenable for three years. These scholarships have been established in order to train promising students under suitable supervision, with a view to their contributing to the development of agriculture, either by carrying out independent research or by acting in an advisory capacity to agriculturists. They will be granted only to students who show distinct promise of capacity for advanced study and research in some one of the sciences bearing on agriculture. Applicants must be graduates of a university or holders of a diploma of a university or college of university rank, and application should be made not later than June 9 next on a form to be obtained from the secretary, Board of Agriculture and Fisheries, Whitehall-place, London, S.W.

AN industrial fellowship in plant pathology for the study of diseases of the potato has been established at Rutgers College, New Brunswick, N. J. Candidates for this appointment should write to Professor Mel. T. Cook at the above address.

GOVERNOR SULZER of New York has signed a law creating a State Board of Geographic Names, which is to consist of five members, of which the commissioner of education and the state geologist are *ex officio* members, and three of whom shall be appointed by the governor. The state geologist is the secretary and executive officer of this board. According to the wording of the law, the board is to have power as follows:

First. To determine and establish the correct historical and etymological form of the place names of the state and to recommend the adoption of such forms for public use.

Second. To determine the form and propriety of new place names proposed for general use, and under the law no corporation, individual or community is permitted to introduce such new place names without the consent and approval of this board.

Third. To cooperate with the United States Board of Geographic Names and with the United States Postoffice Department in establishing a proper, correct and historically accurate form for all place names proposed as designations of new postoffices.

#### UNIVERSITY AND EDUCATIONAL NEWS

BOTH houses of the Minnesota legislature have passed an appropriation bill granting practically everything asked for by the University of Minnesota. The bill carries items as follows:

Maintenance .....	\$966,000
Fuel .....	120,000
Special maintenance .....	462,000
Special agricultural maintenance .....	326,000
Buildings and equipment .....	639,950
Agricultural substations .....	276,500
Special, certificate-plan, bill .....	500,000
	<hr/>
	\$3,290,450

BUCHTEL COLLEGE, a successful institution of forty years' standing, has been offered to the city of Akron, Ohio, for use as a municipal college or university, according to information received at the United States Bureau of Education. The corporation of the college finds that the institution has trebled its attendance in the past ten years without sufficiently increasing its endowment, and proposes to transfer the entire plant and endowment, valued at \$400,000, to the city, practically without restrictions of any kind. If the offer is accepted, Akron will have an educational institution of college grade that will meet the community's needs in a distinctly modern way. It will be known as the College or University of the City of Akron, although in the event of the establishment of other schools or colleges the name Buchtel College is to be

retained for the liberal arts department, just as McMicken College is a part of the University of Cincinnati. In making their proposal the trustees point out, among other things, that as a municipal institution, and with very slight addition to the money now spent for educational purposes by Akron, the college would offer to all qualified students of the city a college education with free tuition; that the college can be made of practical use in the work of city government; and that the college will furnish an excellent basis for a greater municipal university that shall make ample provision for technical and professional training for the youth of the city.

To study the methods by which the University of Wisconsin is serving the state in various ways, a party of fifty public officials and prominent citizens of Philadelphia and other cities of Pennsylvania have arranged an inspection trip to Madison, Wis., for four days, from May 21 to May 25. The Pennsylvanians are particularly interested in the relation of the university to the state, cities and rural communities through the medium of the extension division's municipal reference library, commercial reference library, traveling package libraries, correspondence study courses, health bureau, classwork among students in extension centers in all parts of the state, vocational guidance and continuation school work. The distinctive work being done by the College of Agriculture through its own extension service, which includes demonstrational work on how to grow crops, improve the dairying industry, increase farm profits through the introduction of efficiency in farm management, etc., has also aroused the interest of the delegation from Pennsylvania. The ultimate object of the visit is to develop similar activities in connection with the University of Pennsylvania and Pennsylvania State College. The party will include, among others, Mayor Rudolph Blankenburg, of Philadelphia; Owen Wister, the novelist; representatives from the University of Pennsylvania, Pennsylvania State College and Franklin Institute; public officials from various cities; John P. Connelly, chairman of the

finance committee of the city of Philadelphia, and Morris L. Cook, director of the public works of Philadelphia.

THE trustees of Dartmouth College have voted, after the year 1914, to suspend for the present instruction in the last two or clinical years of the Medical School and to concentrate the resources of the school upon the first two years in medicine. Students thus trained will be well qualified to enter the third year of the courses offered by the best city medical schools and may there complete their clinical preparation for the degree of doctor of medicine. The reason given by the trustees for this action is that because of its location the school has found difficulty in meeting satisfactorily the steadily advancing requirements set by the medical profession for a larger supply and variety of clinical material for purposes of instruction. By the action of the trustees also provision is made to extend the work in business organization and management and in commerce. Principles of business management, heretofore a second-year course, will be given the first year. Professor Person and Henry Woods Shelton, appointed assistant professor, will offer new advanced courses in the application of principles of management in manufacturing and merchandizing, including selling, advertising and other specialized branches.

PROFESSOR ERNEST C. MOORE, head of the department of education at Yale University, has received an offer to become professor of education at Harvard University.

DR. JOEL H. HILDEBRAND, of the University of Pennsylvania, has been appointed assistant professor of chemistry in the University of California.

DR. ERNST HEDINGER, professor of pathological anatomy at Basle, has accepted a call to Königsberg in succession to Professor F. Henke.

MR. A. R. HINKS, F.R.S., chief assistant at the Cambridge University Observatory, has been appointed Gresham professor of astronomy, London, in succession to the late Mr. S. A. Saunder.

At a meeting of the electors to the Plumian professorship of astronomy in the University of Cambridge, held on April 19, Mr. A. S. Eddington, chief assistant at the Royal Observatory, Greenwich, was elected to the professorship, in succession to the late Sir George Darwin.

#### DISCUSSION AND CORRESPONDENCE

##### THE NEED FOR ENDOWED AGRICULTURAL RESEARCH<sup>1</sup>

TO THE EDITOR OF SCIENCE: There exists a widespread confusion of thought in regard to what is needed for the advancement of the science of agriculture in distinction from what is needed for the promotion of the practise of scientific farming. Actually these two things are entirely distinct, and what is of great aid, or even essential to one, is usually of relatively little value to the other, and indeed may indirectly become a hindrance to it. To advance the science of agriculture means to make new and fundamental discoveries in regard to the natural laws on which crop production and animal production depend. To promote such advance plainly demands the conducting of scientific research of the highest type in the field of agriculture and the pure sciences—physics, chemistry and biology—which are fundamental to it. On the other hand, to advance or promote the practise of scientific farming means (a) to put into the hands of the practical farmer the most complete and authentic information which exists

<sup>1</sup> This communication was called forth by the discussion which has been going on in the newspapers regarding the proposed plan of Mr. Vincent Astor to utilize his estate for the promotion of agricultural science. It was originally published in the *New York Times* for February 21, 1913. The editor of that paper, however, saw fit to omit considerable portions of the communication as submitted to him, including the discussion of what I believe to be the most essential point indicating the need for endowed, as supplementary to tax-supported, agricultural research. The result was what I can only regard as an unfair and inadequate presentation of my views on the subject. Since the matter is unquestionably one of real significance to the cause of American science, I venture to offer here a complete statement of my position.

in regard to the scientifically correct principles and methods of farming, and (b) to stimulate him by every possible appeal to reason, ambition and thrift to put these methods into practise on his own farm.

From this brief statement it will be apparent that, broadly viewed, the successful promotion of scientific farming must depend in the long run on the advance made in the science of agriculture. The farmer can not be taught new principles and methods until these have been discovered by the investigator. All federal and state legislation in this country looking towards the development of our agricultural resources has included in its purview these two complementary, but in practise somewhat conflicting needs. But there has been comparatively little effective effort (aside from the Adams Act, which has unquestionably been of great aid to the cause of agricultural research) sharply to distinguish between these needs and to provide definitely and precisely for each. Generally speaking, and with the exception noted, the provisions for tax-supported agricultural work in the United States have attempted to kill two birds with one stone. The result has varied in different localities, but on the whole it may fairly be said that the effect has usually been much more marked on one of the birds than on the other. Undoubtedly this country leads the world to-day in the effective promotion of scientific farming. This enviable position has been gained through our splendidly organized system of agricultural education, comprising the colleges of agriculture in every state with their intramural instruction, on the one hand, and their extension activities, which reach an astonishingly large proportion of the farming population, on the other hand. Furthermore, to supplement the extramural work of the colleges we have the work of the experiment stations and state departments of agriculture and the federal department of agriculture. These institutions reach the farmer in many ways, but chiefly by the dissemination of useful information in the form of bulletins, and other (even more ephemeral) forms of literature. On the whole, it would be difficult, and indeed no one has ever done so, to devise a

better and more effective system for the promotion of scientific farming than that which we now enjoy the benefits of in this country.

But what of the advancement of the science of agriculture? There we meet a totally different condition of affairs. Comparisons are proverbially odious, but I very much doubt if many *disinterested* scientific men acquainted with the field could be found to affirm that in this particular we lead the world. Theoretically it is a primary function of the state experiment stations to conduct researches of a fundamental character which shall be calculated to discover basic natural laws. Actually, with a few rare and partial exceptions, experiment stations do nothing of the sort. On the contrary, what they do engage in is experimental work of a kind carefully calculated to make as strong an appeal as possible on the basis of its supposed "practicality" to the scientifically uneducated and uncritical farmers who make up its constituency. The experiment station investigator in many cases (though happily not in all, as I am able personally to affirm after five years' experience in Maine) is compelled by force of circumstance over which he has no control to supplicate the great goddess Truth with one ear closely applied to the ground in order that he may catch the first and faintest murmur of "what the public wants." If he has the temerity to venture upon a piece of research for which by the most extreme sophistry no evidence of immediate practicality can be adduced, he must do the work *sub rosa* and publish the results in such place that by no possible chance can the constituency ever learn of it.

What has been said can not justly be regarded as a criticism of American experiment stations or their responsible managers. It is simply a fair and candid statement of an existing condition of affairs, which limits the usefulness of experiment stations in certain directions. The reason for the existence of this condition *primarily* lies *not* in any lack of high scientific ideals on the part of the directorate or the workers, nor in any mismanagement, either intellectual or material, of their institutions, *but is found in the fact that they are tax-supported*. The people who

support an institution by the payment of taxes rightly feel that it is their institution. If it engages for a considerable period of time in activities of which they do not approve, or which they regard as useless and frivolous they will either withdraw their support, or if this is practically impossible, they will, by the pressure of public opinion, bring about changes in its management until they get it controlled by men whose policy meets with their approval. Every experiment station worker knows this obvious fact. He must govern his actions in accordance with it if he desires to do *any* useful work in this field. Because of this fact, which is from one point of view a great advantage, the experiment stations have come to take a very important part in the promotion of scientific farming. Their achievements in this direction, viewed as a whole, over the past twenty-five years, are noteworthy in a high degree. But doing this has left but little time, energy, resources or brains available for fundamental research in agricultural science.

The greatest need of organized agricultural development in this country at the present time is, I venture to think, an endowed institution for agricultural research, which shall do for the science of agriculture what the Rockefeller Institute is doing for the science of medicine. This need the state experiment stations never can entirely fill, for the reason that the farmers of the country collectively are not and can not be expected to be qualified to judge either (a) what are fundamental problems or fields in which research should be carried on, or (b) what lines of investigation are likely to advance knowledge, or (c) what are appropriate methods of investigation in general and in particular. Yet these are matters which the interested tax-paying public in actual fact does, and will continue to pass judgment upon in the case of tax-supported institutions. I have no criticism to offer on this attitude of mind. It is human, and understandable, and has led to some excellent results, and I have no quarrel with it whatsoever. I merely affirm that it is not one well calculated to promote the advance of science. He who will endow on a

scale in some degree commensurate with the importance of agriculture in the social and economic system, an institute for agricultural research and place its management in the hands of a board of directors, of which a majority shall be scientific men of standing, will do the world a service of inestimable value.

#### BLOCKS AND SEGMENTS

In the issue of *SCIENCE* for January 31, 1913, Dr. Geo. I. Adams proposes the use of the word *segment* for a general term to be applied to a minor part of the earth having the dimensions of a solid. He finds that this term has already been used in Chamberlin and Salisbury's text-book of geology in discussing continental and oceanic segments and asks, "If it is applicable to major elements, why not to minor ones as well?" The note is not untimely, as it is evident that there are some divergent practices in the selection of terms to denote the categories in question. A quotation is given from a prominent geologist who uses the word *segment* in the way to designate a minor part of the earth's exterior marked off by some structure. It is not evident, however, if the writer of the quotation meant to use it in as wide a sense as proposed in Dr. Adams's note; for it appears that Dr. Adams would apply the name *segment* to all parts of the earth's exterior marked off by faults.

It seems that a term has long been in use, at least among American geologists, to denote a minor part of the earth's exterior marked off by faults. This term is *block*, a short, clear-cut, Anglo-Saxon word, very suitable for such use as is now proposed for *segment*. The use of the word *segment* by Chamberlin and Salisbury is, as it appears to me, for the purpose of denoting parts of the earth, more or less commensurate with the geosphere itself. The term seems very appropriate in that sense. Smaller parts of the earth's exterior, marked off by faults or sharp folds, especially when not discussed in connection

with cosmogenetic problems, ought to be designated by a different term. The need of such a term has long ago prompted its adoption, as will be evident from the following quotations from various text-books and geological papers, selected somewhat at random. "Manual of Geology," Dana, 4th ed., p. 366:

The ridges of the Great Basin . . . have been assumed to be each limited by faults . . . and to have become, in effect, monoclinical orographic blocks.<sup>2</sup>

"Elements of Geology," LeConte, 5th ed., p. 239:

The strata are broken into prismatic blocks. . . . The slipping of these blocks has given rise to cliffs.

"An Introduction to Geology," Scott, 2d ed., p. 5:

Blocks are divided into still larger masses or blocks by . . . fissures and planes of dislocation, or faults.

(Pp. 464 and 465): The plateau of basalt has been fractured into a series of blocks which are tilted. . . .

"Exploration of the Colorado River of the West, and Its Tributaries," Powell, p. 184:

The faults . . . divide the district under consideration into long belts or blocks. . . . In examining the downthrow of these blocks, it is observed. . . .

"Geology of the Henry Mountains," G. K. Gilbert, p. 23:

The strata of the upper part of the arch (of Mt. Ellsworth) are divided (by faults) into a number of prismoid blocks.

"The Geology of the Eastern Portion of the Uinta Mountains," by J. W. Powell, pp. 16, 17:

When the blocks into which a district of country has been broken by faults are greatly tilted . . . the uplifted edges of such blocks often form long mountain ridges. . . . In this region many zones are found to be divided into small blocks by faults. . . . Fig. 4 is a bird's-eye view of the blocks mentioned. . . . Fig. 5 is a diagram of the same region showing the blocks into which it is severed.

<sup>2</sup> Italics here and below by the writer of this note.

. . . Many other areas far more complex than these have been discovered where a zone has been broken into blocks and these blocks tipped and contorted. . . .

"The Ore Deposits of New Mexico," Lindgren, Graton and Gordon, Professional Paper 68, U. S. Geological Survey, p. 25:

The principal disturbances . . . are marked by a series of . . . ranges of apparently tilted blocks.

*Bulletin of the University of Texas*, No. 93;

"A Sketch of the Geology of the Chisos Country," p. 80:

It (the Chisos country) covers a part of a sunken block, which measures about 39 miles from east to west and which has settled from four to six thousand feet below the level of the terranes on either side.

SCIENCE, N. S., Vol. XXXVII., No. 945, p. 226:

Keyes speaks of the "so-called fault-block mountains" and refers to a statement by Spur that no one has ever seen the fault-lines blocking out the desert ranges.

It will be seen from these quotations that block is a term which has long been in use, and which is being used at the present time with a definite meaning, similar to that proposed. It seems to be needed. If retained and used in the same sense as heretofore, it will aid in giving greater precision to the geological nomenclature. We need the term *segment* for a slightly different use, as already stated.

UNIVERSITY OF TEXAS

#### CRITICAL CRITERIA ON BASIN RANGE STRUCTURE

CHARLES R. KEYES in a recent number of SCIENCE<sup>1</sup> presents a note entitled as above in which he expresses in general terms his lack of belief in "Basin Range Structure," so called, and suggests deflative agencies rather than local tectonic displacement as the important factor in the formation of such ranges.

The writer has no desire at this time to defend the hypothesis of basin range structure, though he is thoroughly convinced of the

<sup>1</sup> N. S., Vol. 37, No. 945, p. 226.

soundness of this tenet: but only to right any misconception which may arise from the slightly ambiguous statement made by Mr. Keyes in which the writer's name is mentioned. To be explicit: Mr. Keyes says: "The present sharp meeting of mountain and plain is now explained by causes other than dislocation, through ordinary stream corrosion according to Paige."

The writer wishes to say that in the paper from which the idea above is drawn<sup>2</sup> the process under discussion was the formation of certain sloping planated rock surfaces which though likely to originate on the borders of enclosed desert basins do not in the process of their formation vitiate in any way the hypothesis of basin range structure. In fact, such surfaces may be used to prove (by their elevated positions) the very existence of such faults as are needed to establish the basin range structure. They are but an incident in a long series of changes of which basin range structure itself is but a minor part. After all there is nothing inherently antagonistic in processes of deflation, stream erosion or block faulting. All have operated and are operating to-day and any explanation of physiographic forms or account of physiographic history which would ignore any one of them is open to obvious criticism.

SIDNEY PAIGE

#### AN INVESTIGATION OF A "HAUNTED" HOUSE

CALLER by telephone a few days ago to examine a large and handsome house in the Back Bay district of Boston for the reason that it was acquiring an unfortunate and annoying reputation as being "haunted," the writer found a really serious state of affairs.

The trouble centered in the third and fourth stories, which were occupied by the children and servants—the slumbers of whom were disturbed by strange sensations. It was said to be a common occurrence for servants to awake in the night with a sensation of oppression, "as if some one were tapping upon me," or with a "creeping feeling going all over me with a feeling of being paralyzed." Sounds

<sup>2</sup>Rock-cut Surfaces in the Desert Ranges," *Journal of Geology*, Vol. 20, No. 5, 1912.

were also said to be heard, as if some one were walking about the house or overhead. These sensations often continued after the sleeper was thoroughly awake and even after the lights had been turned on. The children of the family, who also slept on the upper floors, were similarly affected. A little boy, for example, awoke one night and inquired of his nurse why she had been lying on him, and persisted for some time in his delusion. Another child rushed screaming into the nurse's room crying that a man was waking him up, and asking why she let the man frighten him so. The children appeared sluggish in the morning and pale, even cold water losing its power to enliven them.

These and other symptoms were well defined and often repeated, and had extended over the period of about two months during which the family had occupied the house as tenants. Upon inquiry it appeared that previous tenants had been troubled in the same way, matters having reached the point where the servants actually talked of seeing walking apparitions. The present occupant, although not entertaining any vitalistic theory of the phenomena, was fully alive to the reality and gravity of the situation, and anxious to find the underlying cause.

A comparatively simple and mechanistic solution of the problem soon appeared. It had been suspected that the trouble might have its origin in undetected leaks of illuminating gas, and the writer was called in to verify this theory. It developed, however, that the large amount of "furnace" gas escaping from a viciously defective hot-air furnace was quite sufficient to cause the trouble. In this furnace the separation between the fire box and the hot air ducts (upon which the hygienic integrity of the apparatus depends) was badly broken and as a result the inhabitants of the house were bathed in an atmosphere of diluted flue gases. To make matters worse, a small boiler for a steam-heating system had been placed within the fire box directly over the fire, the effect being to cool the top of the fire and so promote incomplete combustion.

In the light of these facts the sufferers' symptoms are readily explained. Flue gases contain, and especially when combustion is incomplete, considerable amounts of sulphurous oxide and carbon monoxide, both distinctly poisonous gases. Furnace gas was common in this house and often very strong—so that the eyes watered and an appreciable effect could be felt in the throat, symptoms at once suggestive of sulphur. The rapid tarnishing of all silver objects was a further indication of the presence of this substance. For the most serious symptoms, however, the responsibility must be thrown on carbon monoxide. The poisonous nature of this gas is too well known to require comment, and sensations of oppression and other mental disturbance are typical of the more acute poisonings, while anæmia, malnutrition, loss of psychic powers and diminished vigor are characteristic of the chronic condition. That the trouble was most aggravated on cold nights—when windows were closed and ventilation poorest, and at the top of the house, is consistent with the furnace explanation. It seems probable that the belief in walking spirits was nourished by real noises coming from an adjoining house. Any such noises would, of course, be likely to be exaggerated in the minds of persons awakened in the night while suffering from carbon monoxide poisoning.

The hygienic lessons are patent. Here is a clear case of thoroughly serious poisoning which might have had at any time a fatal result, and all due to a defective hot-air furnace. This apparatus, often praised for its ventilating effect and probably with justice when in sound condition and properly operated, may evidently become a distinct menace to health. And may not there be similar cases of a milder order, such as escape detection while still causing slight poisoning? Emphasis is also thrown on to the entire question of the possible dangers from flue gases. Brick sewers have been found to be sometimes permeable to illuminating gas; may not these poisonous flue gases sometimes escape into houses through porous or leaky chimneys?

Slight leaks of illuminating gas have often been suggested as a cause of headaches and anæmias of obscure origin; perhaps we should look to leaky furnaces and flue gases for similar effects.

This case should also be of interest to experimental psychologists and investigators of psychic and spiritualistic manifestations, since the reputation which this house was gaining as being haunted apparently arose in large measure from genuine sensations of apparitions and the like, induced by the breathing during sleep of a tainted atmosphere.

FRANZ SCHNEIDER, JR.

DEPARTMENT OF BIOLOGY AND PUBLIC HEALTH,  
MASSACHUSETTS INSTITUTE OF TECHNOLOGY

#### SCIENTIFIC BOOKS

*Das Erdöl.* Seine Physik, Chemie, Geologie, Technologie, Und sein Wirtschaftsbetrieb. In fünf Bänden. Herausgegeben von C. ENGLER und H. v. HOEFER. Leipsig, verlag von S. Hirzel. 1912.

With the vanishing supply of natural gas, and the diminishing output of the world's stock of light petroleum, this work appears at an opportune moment. The first volume edited by Dr. Engler under the title "*Die Chemie und Physik des Erdöls*," and just issued, contains 855 pages with full index, and 18 large plates, the latter giving complete analyses and optical activity of petroleum from the principal fields.

The scope of this work and its comprehensive magnitude as indicated by its title and fully substantiated by the first volume, promises the most thorough and complete compilation on petroleum and its products that has ever appeared. It is fortunate that its preparation was undertaken by two such well-known workers in this field. The name of Dr. Engler especially is familiar to every one who is interested in petroleum.

Since the comprehensive report on petroleum by Peckham, to the United States Geological Survey,<sup>1</sup> the great accumulation of lit-

<sup>1</sup>Report on the Production, Technology and Uses of Petroleum and its Products, Government Printing Office, 1885.

erature on petroleum has been partly summarized by Redwood,<sup>2</sup> by Richardson<sup>3</sup> and by Clarke.<sup>4</sup> It was evidently the plan of the authors of "Das Erdöl" to include all that is known concerning petroleum, and one does not proceed far in the perusal of this volume to be convinced that their object will be well attained. It is safe to assert that this work will be found readily accessible for convenient consultation by the investigator, experimenter and refiner, for it will be an indispensable aid to every one interested in this subject.

This volume is devoted to the varieties of bitumen as a generic term for solids and liquids, and to natural gas, their composition, genetics, occurrence, chemical and physical properties, optical characters, heats of combustion, fractional distillation and lubrication. But much the larger space is devoted to the composition of petroleum and its products, with a complete review of the series of hydrocarbons that have been found in petroleum, and the structural relations of the various series on the basis of the most recent classification of the hydrocarbons.

There is a full discussion of all investigations of petroleum from the beginning, and large space is given to the work on American petroleum. The identity of the naphthenes first discovered by Markownikow in Russian petroleum with the same constituents in American petroleum, and with the more recently synthetically prepared cyclo-hydrocarbons, is fully set forth.

It is gratifying to observe that the proof of the absence in any appreciable qualities of ethylene hydrocarbons, especially from American petroleum, is comprehensively presented, for the erroneous statements on this subject in all works on petroleum have been grossly misleading. An interesting résumé is given of the facts and theories relating to the natural formation of petroleum from a chemical

point of view. The behavior of petroleum and its products towards reagents, the action of atmospheric agencies, oxygen and ozone, as well as light, are critically considered.

The complete description of crude petroleum from all well-known fields, including its composition and properties, will be serviceable to the prospector and the refiner. Pyrogenic decomposition under various conditions, with what is known to the refiner as cracking, receives careful attention, as does also such subjects as absorption, capillarity, conditions and limits of explosion, and physiological effects. Considerable space is devoted to lubrication and the efficiency of lubricants. The theory of viscosity and the laws and practical operation of frictional testing machines are presented, with comprehensive tables and ordinate diagrams of the relative and absolute viscosity of the hydrocarbons, both paraffine and aromatic.

Reference is made to the lack of efficiency of dry lubricants and attention is called to the great advantage of a combination of an oil lubricant with graphite in such form that it reduces very materially the coefficient of friction by saturating the bearing with graphite, and at the same time forming a coherent film. It is explained that the difficulty of obtaining graphite in a sufficiently fine condition has been overcome by the colloidal graphite recently discovered by Dr. Edw. G. Acheson which is used in the form of oildag, a suspension of colloidal graphite in a suitable oil or in the form of aquadag, a suspension in water. Diagrams and results of frictional tests on the Carpenter machine are presented, from which the following interesting conclusions are translated.

These experiments confirm also the theory that a proper use of the combined oil-graphite lubricant is in high degree profitable. Besides the reduction of the coefficient of friction which is important from an economical point of view, a material saving in wear of bearing surfaces and of the lubricant required are other essential features in reducing the operating cost. Then, too, the factor of safety in operating is essentially larger and the danger of overloading much less than with lubricants containing no oildag. These

<sup>2</sup>"Petroleum and its Products."

<sup>3</sup>"The Modern Asphalt Pavement," J. Wiley & Sons.

<sup>4</sup>"Data of Geo-chemistry," U. S. Geological Survey, 1908.

factors should be of especial importance in the lubrication of motors, flying-machines, automobiles and similar machines.

The work is presented in regard to paper and printing with the characteristic skill and care of the German publisher, and with the patient thoughtfulness on the part of authors and publisher that we are led to expect in German publications.

CHARLES F. MABERY

*Applied Biology.* An elementary text-book and laboratory guide. By MAURICE A. BIGELOW, Ph.D., Professor of Biology in Teachers College, Columbia University, and ANNA N. BIGELOW, Teacher of High School Biology. 8vo. Pp. xii + 583. New York, The Macmillan Company. 1911. \$1.40 net.

*Teacher's Manual of Biology.* A handbook to accompany the preceding. By MAURICE A. BIGELOW, Ph.D. 8vo. Pp. viii + 113. New York, The Macmillan Company. 1912.

Readers of SCIENCE have sometimes been entertained by bursts of eloquent disapproval of all courses in general biology. Certain noted botanists especially have been wont to speak of such courses as impossible, decadent, reprehensible; as maladies of a peculiar American epidemic, that has, happily, long since run its course. Their ills have been solemnly charged against presumptuous zoologists who have rushed in where modest botanists fear to tread. Fie on any one who would teach about plants and animals in the same course!

This protest has been loud—perhaps a bit too loud; for certain it is that courses in general biology were never so widespread as at the present time, nor were there ever so many new text-books offered for such courses, not only in America, but in Germany and France as well. Perhaps the reason lies in a permanent educational need, which such courses fulfill. There are those who have tried to test the matter by scientific methods who think so.

Among the many new books offered in this field is an important one by the Bigelows for secondary schools. Its title is "Applied Biology," but, fortunately, the applied part of it is mostly in the title. It would be an important book, if for no other reason, because

it represents a great deal of honest effort on the part of competent teachers of extensive and varied experience, to put together into one consistent course what they deem best of all that they have tried. One does not need to be committed wholly to its plan in order to agree that it has been carefully laid out, and based on long experience and good judgment.

It is a conservative book. It begins with a chapter on definitions and another on the distinctive characteristics of living things (22 pages). Then follow chapters on the frog and the bean plant, these two types serving as an introduction to animal and plant biology respectively (122 pages). Then follow the more customary series of plant and animal types, the plants in descending, the animals in ascending series (300 pages), leading to a concluding part devoted to the consideration of the principles of biology as applied to human structure and life (118 pages). In all this there is much careful culling of both subject matter and methods: and a well-balanced indoor course for city schools is the result.

The biology taught is distinctly that of the laboratory—not of the outdoors. While there are here and there hints of the existence of outdoor biological phenomena, there is no plan provided for the study of them.

The technical terms used are few, but adequate. One notes almost with surprise how great is the gain resulting from the omission of most of the rubbish of terminology that encumbers the average high-school text. Of more doubtful value is the relegation of most of the laboratory work to demonstration by the teacher. Though this saves time and yields fewer failures of individual experiments, one may well doubt whether the pupil will learn, by handling pen and paper and recording results, what the handling of the things would teach him.

The illustrations are old—some of them so old that the original sources appear to have been lost. The authors seem to think that "well-known figures from standard biological works are to be preferred to new ones." At least, they are cheaper. One notes with regret the perpetuation of the grossly inaccurate fig-

ure of a mayfly nymph (from Parker & Haswell) on page 399; also the confusion of the lettering in figure 32 on page 79 (from Bessey), and the use of the word ovary with very different meaning in this figure and in one on page 244.

Biological pickles do not seem, as a rule, to excite much enthusiasm on the part of a beginner of high-school age and exception may be taken, therefore, to the suggestion on page 389 that for practise with insects "a mixed lot preserved in wood alcohol or formalin is best." But, as a rule, the suggestions as to laboratory methods are excellent and the book, as a whole, is a valuable contribution to the literature of biological laboratory methods.

JAMES G. NEEDHAM

CORNELL UNIVERSITY

THE SO-CALLED AEROSTATIC HAIRS OF CERTAIN LEPIDOPTEROUS LARVÆ

IN his valuable report on the dispersion of the gipsy moth,<sup>1</sup> Mr. A. F. Burgess emphasizes the very great rôle which is played by the wind in distributing the first-stage caterpillars. In this connection he calls attention to, and figures the so-called aerostatic hairs arising from tubercles in first-stage larvæ of the gipsy moth, though he does not commit himself to the theory that they, with their globular swelling at the base, actually aid in making the caterpillars more buoyant.

These peculiar hairs, to be found on first-stage larvæ of the nun moth, as well as of the gipsy moth, were first described by Wachtl and Kornauth<sup>2</sup> under the name of aerostatic setæ, while they designated the balloon-shaped swellings as aerophores. They have been subsequently noted by several workers.

As indicated by the name, the aerophore was supposed to be filled with air, and Wachtl and Kornauth believed that the aero-

static bristles presented a collection of balloons which function as an aeronautic apparatus. If their interpretation be correct, it is obvious that in both the nun moth larvæ and in the gipsy moth larvæ these structures play a very important rôle in aiding the dispersal of the species by the wind.

Those who hold to the view that the swellings are in reality aerophores have not sought to explain how it is that the almost microscopic structures should serve as "balloons" if they are filled with air. A balloon rises because it is filled with gas lighter than air. To be sure, Fernald<sup>3</sup> suggests that they are distended with air "or gas," but it is difficult to conceive of a possible source of a special gas.

Apparently, Professor Cholodkovsky was the first to suggest the true nature of the so-called aerostatic hairs. First, in a Russian forestry journal and then in Tubeuf's *Zeitschrift*<sup>4</sup> he called attention to certain serious objections to Wachtl and Kornauth's hypothesis. The fact that the swellings, or vesicles, shrink in dead larvæ, militates against the view that they are filled with air. On the contrary, it favors the view that they contain a fluid which, after the death of the larvæ, naturally must dry up. In larvæ preserved in alcohol, air-filled organs would soon lose their air content, but these vesicles remain for months as full and rounded as in the living larvæ. If such a preparation is allowed to dry on the slide all of the "aerophores" quickly shrivel.

Cholodkovsky, therefore, suggested that the swellings were not filled with air, but with a fluid, and that very probably this was a poisonous one, since the larvæ, in this stage especially, need protection against insectivorous birds. This view was confirmed by the study of sections, which showed a large, unicellular gland underlying each of the "aerostatic bristles" and opening directly into the cavity.

<sup>3</sup>Rept. on the Gypsy Moth, Mass. Board of Agr., 1896, pp. 300-301.

<sup>4</sup>Cholodkovsky, N., "Ueber die sogenannten Aërophore der Nonnenraupe," *Forstlich-naturwissenschaftliche Zeitschr.*, III., pp. 240-243, 1894.

Subsequently Ingenitzky,<sup>5</sup> a student of Professor Cholodkovsky's, made a much more detailed study of these glands and distinguished them clearly from the trichogens, the enlarged hypodermal cells which give rise to the hairs.

It seems, then, very clearly established that the so-called aerophores have no function of rendering the larvæ more buoyant, but are really *toxophores*, as Cholodkovsky proposed to call them. The rôle of rendering the larvæ more buoyant may much better be ascribed to the long, thin hairs which, as the Russian observer points out, have an unmistakable resemblance to the pappus of some plant seeds.

WM. A. RILEY

#### SPECIAL ARTICLES

IS THE BIENNIAL HABIT OF *CENOTHERA* RACES  
CONSTANT IN THEIR NATIVE LOCALITIES?

THE recent article<sup>1</sup> on "*Cenothera* and Climate," by R. R. Gates, is of particular interest to me since, for the past few years I have had in culture several of the races of *Cenothera* "*biennis*" from the vicinity of Ithaca, N. Y. Two (possibly three) of these races which are predominantly biennial in character have in culture in their native locality produced annual individuals. In one case (No. 2, *Cenothera nutans*) the seed was planted during March, 1911, and in May the boxes were kept in the garden with one transplanting until June, when they were transplanted in the open garden. From the experiences of the season of 1912, these rosettes of 1911 started in the greenhouse in March were not so far advanced as they would have been had the seed been planted in the open garden in April. Three out of about 50 or 60 came into flower early in September. Rosettes of the intermediate stage were well formed in August but these three individuals did not form the dense rosettes so characteristic of the others in late autumn. Two of these September flowering individuals were potted and taken into the

greenhouse, where they flowered all winter. In the spring they were removed to the garden and kept in their pots, where they continued to flower until some time in August, thus flowering continuously for eleven months. Another race (No. 1, *Cenothera pycnocarpa*) under the same conditions remained strictly biennial.

In a third race (No. 17) seed was planted directly in the garden in the early spring of 1912. Eight or ten out of about 200, without the formation of rosettes, came into flower in August, matured seed and died. They were strictly annual. The others are now in the rosette stage.

In another race (No. 16), possibly identical with No. 2, the seed was planted directly in the garden on the same day as No. 17. Out of about 300 individuals one did not form a rosette. It came into flower in August, formed seed and died late in September. This individual was annual, but it remains to be seen if it is a mutant from this race, which can not be determined before the rosettes of the other individuals now passing the winter have come into flower.

From my experience in the culture of *Cenotheras*, which is not extensive it is true, I have come to the conclusion that their behavior as to a strict biennial habit even in their native locality may be different under culture either in the garden or greenhouse from what it is in the open under feral conditions. Fully formed rosettes potted in the autumn and taken into the greenhouse, kept there during the winter and removed to the garden in the spring did not form stems nor come into flower any earlier than those which wintered in the garden.

Another feature of considerable interest which has appeared in connection with some of my cultures may be mentioned here, but an account of the more important results are reserved until after another season's experiences. The feature to which I refer is the possibility of certain races of *Cenothera* becoming perennial or of taking on a perennial habit under certain conditions. Several plants of *Cenothera nutans* which matured in

<sup>5</sup>Ingenitzky, I., "Zur Kenntniss der Drüsenhaare der Nonnenraupe (*Ocneria monacha*)," *Horæ Soc. Ent. Rossicæ*, XXX., pp. 129-134, pl. VIII, Figs. 9-11, 1896.

<sup>1</sup>SCIENCE, N. S., 37: 155, 156, 1912.

late August and early September, were observed during late September and early October, after prolonged rains, to be putting out new branches which came into flower. Some of the stems of those which were dead formed distinct and strong rosettes from the root stock as lateral branches. If these survive the winter the rosettes will probably form stems and the plants will come into flower a second season, that is, the third season from the rosette stage. It would then be a perennial with the habit of a perennial root stock and annual flowering shoot. Several of the individuals which were putting out new branches in late September and early October were potted in early November and removed to the greenhouse where they have continued to produce new shoots, often slender and crowded, sometimes suggesting "witches' brooms." These branches arise from the old brown stalk which to all external appearance one would consider dead but on cutting the stem chlorophyllaceous tissue is seen. The very dark sky during December and January has been unfavorable for growth or flowering, and perhaps accounts to some extent for the spindling growth and lack of flowers during this period. On some of these plants the new growth occasionally wilts down, indicating perhaps that the old stems are somewhat deficient in conduction. After reading Mr. Gates's article (Jan. 24, 1913) I stepped into the greenhouse to see my perennial *Oenotheras* and lo, there was one flower.

This plant (of *Oenothera nutans*) continued to flower in the greenhouse until the middle of April when it was transplanted into the garden. The cold weather following proved to be too great a change from the warm air of the greenhouse and the stems died to the ground, but a small rosette which had formed from the root stock remains alive to this day (May 2). Three of those individuals which formed rosettes during the autumn and were kept over in the garden or in a cold frame have been transplanted to the garden. They are doing well and will probably produce stems and flowers this summer. These individuals, therefore, of *Oenothera nutans* have taken on a perennial habit.

These two species, No. 2, *Oenothera nutans* Atkinson and Bartlett, and No. 1, *Oenothera pycnocarpa* Atkinson and Bartlett are described in the May number of *Rhodora*, 1913.

CORNELL UNIVERSITY

#### THE LOWER CALIFORNIA PRONGHORN ANTELOPE

THE Pronghorn of Lower California has recently been separated by Mr. E. W. Nelson as a sub-specific race. (*Proc. Biol. Soc. of Wash.*, Vol. 25, page 107.) The characters given have to do mostly with color and color pattern, while the horns are mentioned as shorter, rougher, more upright and less diverging than in either of the other forms, *americana* and *mexicana*. No mention is made of skull characters.

A fine series of six adult males and several females were recently sent to me from Calmali, L. C., the type locality of the new form. One of these males is now in the collection of the Biological Survey at Washington; the others are in the Museum of Comparative Zoology.

I have not compared the skins of these specimens, but careful measurements of the six skulls do show a real divergence when compared with five large male specimens from the Laramie Plains, southeastern Wyoming, in the Museum of Comparative Zoology. They are on an average longer in the face, and considerably narrower. The most significant measurements are: length of nasals, length of anterior nares, and smallest width between orbits. The nasal length of the California animals runs from 101 to 110 mm., while the Wyoming specimens show from 84 to 97 mm. Likewise the width between orbits scarcely overlaps in the two series. An arbitrary index of nasal length plus length of anterior nares, divided by width between orbits, gives for the *peninsularis* series 1.73, and for the *americana* series 1.51.

The occipito-nasal length is very much more uniform in the series of *peninsularis* than in that of *americana*, and is somewhat greater.

One specimen from Calmali, original No. 65, shows such an abundant horn development that it ranks fifth largest as to length of horn in Rowland Ward's list (sixth edition). The horns, sixteen and one eighth inches long, show a remarkably divergent tendency, there being seventeen and one half inches between them at the fork. The base measurement is six and one quarter inches, and the general form is clean and symmetrical, not stumpy, knobbed and aberrant-looking like some of the others from the same locality. There seems to be, however, in all the California horns a tendency to a very sharp angular bend at the terminal portion, instead of a gentle or even curve. Therefore this new race of Pronghorn has a characteristic skull modification and can at times produce fine typical horns, in spite of its seemingly unfavorable environment.

The type locality of *A. americana* is an indefinite one and is referred to the Plains of the Missouri. The five *americana* skulls used for comparison were taken near Percy, Wyoming, and are Nos. 43, 46, 49, 50, 52 in the Museum of Comparative Zoology.

J. C. PHILLIPS

WENHAM, MASS.

#### THE AMERICAN PHILOSOPHICAL SOCIETY

THE annual general meeting of the American Philosophical Society was held in the rooms of the society in Philadelphia, April 17 to 19, inclusive, and constituted a most notable series of sessions. There were a large number of papers presented, their general character being of a high order of merit and the scope of subjects included wide.

The meeting was opened on Thursday afternoon, President W. W. Keen, LL.D., in the chair, when the following papers were read:

*The Biographies of Suetonius*: JOHN C. ROLFE, Ph.D.

*The Etymology of the Word "Ill"*: HERMANN COLLITZ, Ph.D.

While most etymologists agree in regarding the word "ill" as a loan word from Scandinavian, no plausible etymology has as yet been given of the old Norse word ("illr") from which it is derived. The traditional etymology of the latter word, identifying it with English "evil," is untenable, for

phonetic reasons. Both the form and the meaning of this word, however, may be accounted for by regarding it as the Scandinavian equivalent of the English word "idle."

*The Treaty Obligations of the United States relating to the Panama Canal*: CHARLEMAGNE TOWER, A.B., LL.D.

Former Ambassador Tower discussed the basis upon which the Hay-Pauncefote treaty was concluded with Great Britain, and pointed out the legal obligation of the United States arising therefrom. He went back to the earliest discoverers and navigators and brought up to the present time the history of the governments of Central America, to show our connection with the enterprise of constructing the canal.

He quoted the Clayton-Bulwer treaty, signed in Washington in 1850, by which the governments of the United States and Great Britain declared that neither would ever obtain or maintain any exclusive control over the ship canal, would fortify or colonize, or exercise any dominion over Nicaragua, Costa Rica, the "Mosquito Coast" or any part of Central America.

Also, that neither Great Britain nor the United States would take advantage of any intimacy or alliance that it might have with any government through whose territory the canal should pass, to acquire or hold any rights or advantages in regard to commerce or navigation which should not be offered on the same terms to the citizens or subjects of the other.

By the Hay-Pauncefote treaty of 1901, Mr. Tower said that, being desirous to facilitate the construction of a ship canal to connect the Atlantic and Pacific Oceans, by whatever route might be considered expedient, and to remove any objection which might arise out of the Clayton-Bulwer treaty to the construction of such canal under the direction of the United States, without impairing the general principle of neutralization, the two nations agreed that the Hay-Pauncefote treaty should supersede the former treaty.

It was agreed also that the canal should be built by the United States, which should enjoy the exclusive right to provide for the regulation and management of it. To make the understanding between the two nations plain, the following specific stipulation was entered into:

"The United States adopts as the basis of the neutralization of such ship canal, the rules substantially as embodied in the Convention of Constantinople, for the free navigation of the Suez Canal, and further, 'The Canal shall be free and

open to the vessels of commerce and of war of all nations observing these rules, on terms of entire equality, so that there shall be no discrimination against any such nation or its citizens or its subjects, in respect to the condition or charges for traffic or otherwise.' "

In view of all this the speaker urged that the United States is in honor bound never to do or allow anything which can be interpreted as in any way inconsistent with the terms of our treaties.

*A Counsel of Perfection. A Plan for a State University and for an Automatic Collection and Distribution of a State Tax for Higher Education:* JOSEPH G. ROSENGARTEN, A.M., LL.D.

In view of the proposed convention to revise the constitution of Pennsylvania, it may not be inappropriate to urge the preparation, consideration and discussion of a provision in the constitution for a mill tax for higher education in Pennsylvania.

The founder of the Philosophical Society was also the founder of what is now the University of Pennsylvania.

From the suggestion of a building big enough for George Whitfield's great audiences, Franklin drew the inspiration in 1740 for the Academy of Philadelphia, which grew into the College of Philadelphia, the University of the State of Pennsylvania, and the University of Pennsylvania of our own day.

Franklin (to-day Franklin and Marshall) College, of Lancaster, Pa., was a tribute paid to him in the closing years of his long useful life by his admiring contemporaries.

The constitution of Pennsylvania, adopted in his lifetime, pledged the support of the state to the university.

To-day there are, as reported by the National Bureau of Education, 87 state universities, and other state-aided institutions of higher education. More than twenty-five of them receive the proceeds of the so-called mill tax rate, varying in amount and methods of collection and distribution. Notable among them is the University of Wisconsin, with a tax of three eighths of a mill, yielding \$1,103,029, with a total income from the state of \$1,552,398, and from the United States of \$80,000, under the Morrill land grants, and returning to the state a large and varied service in public work and commissions of many useful kinds.

Under the same fostering care, other state universities have grown rapidly into importance—notably Michigan, Indiana, Colorado, Illinois, Iowa, Kansas, Nebraska, Texas, and state aid thus

secured by the mill tax has been supplemented by many magnificent gifts from individuals.

The question of how best to make constitutional provision for higher education has been discussed, and its advantages affirmed by Andrew White, of Cornell; President Swain, of Swarthmore; President Beardshear, of Iowa; President Jesse, of Missouri; Professor Herbert B. Adams and Professor Maphis, of the University of Virginia; Professor Lefevre, of the University of Texas; President Ellis, of Ohio, and by the representative educational leaders from all parts of the country.

In Pennsylvania, with a state revenue of over thirty millions, a mill tax would produce an income large enough to support all the universities and colleges and institutions of higher education in a way to make them of infinite benefit and credit to the state.

With a provision in the constitution for such a mill tax for higher education should go power in the legislature to create a state board of education, including in it the governor and principal officers of the state *ex officio* and representatives of universities and colleges and technical schools and museums.

Let the state be divided into three sections, eastern, middle and western, each with its local educational council, consisting of representatives from all the institutions of higher education in the section, these in turn to send one or more representatives to the state board of education. That body could frame a plan on which the proceeds of the mill tax should be distributed, according to numbers, standards, efficiency and other conditions prescribed for a share of the income from the mill tax.

In due time the weak colleges would see the advantages of union with others, thus increasing efficiency.

The University of Pennsylvania would naturally be the head of higher education in and for the state, other universities and colleges being affiliated with it.

State College should be made the great agricultural school for the state, attracting to it all branches affiliated in that important work, veterinary schools, forestry, conservation of natural resources, etc.

The University of Pittsburgh would be the head of higher education in the western part of the state, and naturally would become the center of all work for educating men in mining, metallurgy, electricity and the other arts and sciences needed in developing the great resources of the state.

Technical schools, the Franklin Institute, the Drexel Institute and similar bodies, as well as such institutions as the Academy of Natural Sciences, the Academy of Fine Arts, the Carnegie Institute of Pittsburgh, should be affiliated.

All degrees in course should be granted by the board of education through the University of the State of Pennsylvania, and to it should be affiliated all examining boards, such as those that now admit to the practise of law, of medicine, of pharmacy and of other professions requiring a state license.

In this way the state would unify and advance the work of higher education.

From the state board of education should come appointments for all scientific and technical commissions, thus enlisting for the state and its needs the service of trained experts in law and legislation, in medicine and the prevention of disease, in mining and other branches of scientific and technical subjects of inquiry.

Such commissions would go far to make a substantial return to the state for the income from a mill tax.

The preparation of a code of laws for the distribution of such an income could follow a provision in the proposed new constitution for the automatic collection of such a state mill tax for higher education.

A similar constitutional provision might be made for a tax for the support of purely public charities, under such regulations as would secure to the state and its people the highest efficiency and the most economical management of hospitals, homes, asylums for the insane, the blind and defectives and dependents.

The state board of charities should be given large powers of inspection and require standards of excellence that would put all such institutions in the highest state of efficiency.

Uniform methods of accounting, supervision of purchases of supplies, constant interchange of officers in charge would secure reforms that of themselves would invite increased gifts from individuals.

With a state mill tax for higher education and for purely public charities, Pennsylvania would take its place with the great western states, in which, with this fostering care, universities have rapidly grown great, in useful work and good results as well as numbers.

*Reprisals, Contraband and Piracy under Queen Elizabeth:* EDWARD P. CHEYNEY, A.M., LL.D.

The English had the reputation in the sixteenth

century of being the greatest pirates in Europe. Everywhere that English ambassadors went they were forced to hear complaints of the seizures at sea by their fellow countrymen. The Venetian governor of the Island of Zante reports to his home government, "I am firmly convinced that there is not a sailor of that nation that is not a pirate." The reasons for this bad reputation were fourfold. In the first place many letters of reprisal were given by the government. Admiralty courts in many countries were inefficient or not inclined to do justice, and English merchants, after failing to obtain justice for injuries suffered, appealed to their own government and were given letters of mark and reprisal authorizing them to reimburse themselves from the property of fellow countrymen of those who had injured them, even though the governments of the two countries were in close alliance. These letters of reprisal were objects of value and were sold, divided, bequeathed or seized for debt; whoever possessed one having a right to seize goods from foreigners up to the value expressed in it. Seizures made on the authority of such letters seemed legal enough to the possessors, but they were scarcely distinguishable from piracy in the eyes of those whose goods were seized. After 1585, when Spain seized the English ships that were then in her harbors, the English government gave these letters still more freely to any one who could bring forward any shadow of proof that he had lost goods in Spain. This practically amounted to privateering against that country.

Secondly, Spain was largely dependent for food and warlike supplies on France, Holland and the countries along the Baltic. When England and Spain went to war England declared all such supplies contraband and seized ships of those nations taking such goods to Spain. The law of contraband was not yet well developed and the merchants whose goods were seized naturally resented it and declared the actions of the English captains piracy.

Adventurers with letters of reprisal, privateers and captains in the Queen's service seizing contraband, all had commissions for what they did. But there were many genuine English pirates who had no commissions. Their names became famous, they were very bold, were often in collusion with fitting-out merchants on shore or with petty officials of the coast districts, and were comparatively seldom captured or punished. They attacked English and foreign vessels alike and threw overboard passengers and sailors and carried away ships and

goods. In 1573, when the Earl of Worcester was on his way to France to represent the Queen at the christening of the French King's daughter, some pirates swooped down on his ship and carried away all valuables, including the christening presents for the little princess.

The punishment of pirates was very difficult. The usual criminal courts would not act beyond the confines of their own countries and pirates' crimes were usually committed on the high seas. Therefore special courts had to be constructed for their trial. Nine hundred and sixty men were indicted in the special admiralty courts for piracy between 1568 and 1600. When convicted, pirates were usually executed on Wapping on the Thames, a mile or two below London. Twenty-eight were hung there in the year 1575 and fourteen in 1579. A narrative still remains of a pirate named Walton, being led from Southwark to Wapping to be hung, tearing strips from his breeches of crimson taffeta and handing them as keepsakes to his friends who followed him. The government also made strenuous efforts to put down piracy by the appointment of special commissions to hunt out pirates and their confederates and by sending fleets to sea to capture them.

There was, therefore, no lack of actual piracy, but probably not more on the part of the Englishmen than of men of other nationalities. The reason for the especial reputation of the English in this regard was that in addition to piracy of the usual kind they were held responsible for the seizures by letters of reprisal and by privateers and for carrying out the practise of capture of contraband goods, to which England was naturally led by the economic dependence of Spain and her own advantageous geographical location.

*Some Commercial Transactions in Babylonia during the Period of Greek Supremacy:* ALBERT T. CLAY, A.M., Ph.D.

*The Historical Value of the Patriarchal Narratives:* GEORGE A. BARTON, A.M., Ph.D.

The science of history has revolutionized our knowledge with reference to the early history of all peoples, showing that the traditions of nations usually begin with mythical stories, which give place gradually to legends, and later emerge into history that is attested by approximately contemporary documents. Inevitably in the progress of knowledge scientific methods have been applied to sacred history. To-day scholars are divided, so far as the patriarchal narratives are concerned, into three groups. (1) The sincere, open-minded, reverent scholars, who believe that the scientific

methods must be applied to the beginnings of the history of Israel as to those of other nations. (2) The reactionaries, who resent the application of scientific methods to ancient history. (3) The mythological, or pseudo-scientific school, which has become enamored of the scientific method from afar, but has never undergone real historical training. This school would regard most of the Biblical characters as mythical.

The tenth chapter of Genesis personifies Egypt, Elam, Assyria and many other nations as men. We know that these nations were not descended from one man. Whenever, then, we find a patriarch and a nation or tribe bearing the same name, it is scientific to assume that the patriarch is a personification of the nation or tribe. Arabian tribal traditions afford similar analogies. The twelve sons of Jacob are, then, the personification of the twelve tribes, and their history is tribal history. This was shown to apply to all but Joseph. There never was a tribe Joseph, but two tribes, Ephraim and Manasseh. The marriages of Jacob represent tribal alliances. Neither Joseph, Jacob nor Abraham can be accounted for in that way, as there were no tribes bearing these names. Are these three patriarchs, accordingly, nothing but myths? Is Abraham a moon-god as the pseudo-scientific school holds? Jacob-el, Joseph-el and Abraham were shown from Babylonian inscriptions to have been personal names in Babylonia before 2000 B.C., Jacob-el being sometimes even there shortened to Jacob. Records of Egyptian conquests of Palestine show that there were cities in Palestine named for a Jacob-el, a Joseph-el and an Abram. Many sources point to migrations from Babylonia to Palestine. Probably such men, heading migrations of Amorites, settled in Palestine and cities were named after them, just as we have our Jonesvilles, Billings, etc., in this country. When later Hebrews settled in these cities they gradually took over the names of the men from whom the cities were named, and wove them into their traditions. Around these names traditions gathered from many quarters were crystallized. These traditions can often be shown to embody real history, though history of a different sort from that supposed by the unscientific student of the Bible. Historical study thus makes it more probable that real men stand behind the stories of Joseph, Jacob and Abraham and that they are mythological personages. Many documents were quoted to substantiate the positions taken. One of the most interesting is a contract in which Abraham took part. It reads:

"1 ox, broken to the yoke,  
 an ox of Ibbi-Sin son of Sin-imgurâni,  
 from Ibbi-Sin  
 through the agency of Kishti-Nabium,  
 son of Eteru,  
 Abarama (i. e., Abraham) son of Awel-Ishtar  
 has hired for 1 month.  
 For 1 month  
 1 shekel of silver  
 he will pay.  
 Of it  $\frac{1}{2}$  shekel of silver  
 from the hand of Abarama  
 Kishti-Nabium has received."

*The Succession of Human Types in the Glacial and Interglacial Epochs of the European Pleistocene:* HENRY FAIRFIELD OSBORN, D.Sc., LL.D.  
*The Flora of Bermuda* (illustrated): STEWARDSON BROWN. Introduced by Professor Henry Kraemer.

In the studies of the land flora of Bermuda which have been carried on since September, 1905, in cooperation with the New York Botanical Garden, the islands have been visited during parts at least of all the months of the year except January, July and October. More than 1,450 separate collections of plants have been made from all parts of the archipelago with the exception of a few of the smaller islands which are only rocks with but little vegetation. The native species of flowering plants and ferns exclusive of the endemic forms number 155, all of which are identical with those existing on the American mainland or the west Indian islands. The fourteen endemic species, four of which have been added through these studies, are all more or less nearly related to those of the southeastern United States, West Indies or tropical continental America and probably derived from such ancestors by modification during long periods of isolation. It would appear, therefore, that the greater portion of the native flora has come to Bermuda from the southwest through the agency of ocean currents, hurricane winds and migratory birds, of which a considerable number of species visit the islands regularly each year.

*A New Type of Sewage Disposal Tank:* WILLIAM PITT MASON, M.D., LL.D.  
*Determination of Uranium and Vanadium in Carnotite Ores of Colorado:* ANDREW A. BLAIR.

FRIDAY, APRIL 18—MORNING SESSION

William W. Keen, M.D., LL.D., president,  
 in the chair

*The Uses and Needs of Selachology (The Study of Sharks and Rays):* BURT G. WILDER, M.D.

*Interpretations of Brain Weight* (illustrated):  
 HENRY H. DONALDSON, Ph.D., D.Sc.

*The Correlation of Structural Development and Function in the Growth of the Vertebrate Nervous System* (illustrated): GEORGE E. COGHILL, Ph.D. Introduced by Dr. H. H. Donaldson.

Recent studies in comparative neurology have resolved the central nervous system of vertebrates into four longitudinal divisions which are severally functional units. Among lower vertebrates the relative development of these divisions, the somatic sensory, the visceral sensory, the somatic motor and the visceral motor, has been in a significant manner correlated with the behavior of the species. Such correlations by the comparative method formed the point of departure for this study on the correlation of the behavior of embryos with the developing structures in the growth of the nervous system.

Embryos of Amphibia are found to be somatic sensory and somatic motor organisms. They give no evidence of visceral nervous functions until after the locomotor mechanism has become established. This mechanism develops out of three types of nerve cells, sensory, associative and motor. The sensory system of the trunk is formed of the giant ganglion cells of the spinal cord, which connect with the skin by means of dendritic processes. This sensory system of the trunk becomes functional earlier than does the sensory system of the head, which is the definitive system of cranial nerves. The associative cells form a ventral commissure between the sensory cells of one side and the motor cells of the other. The motor cells hold a relatively ventral position in the spinal cord and lower portion of the brain. They form a continuous motor column and tract on either side and connect with the muscles by means of collaterals from their axones. The development of this system of reflex arcs with a single final common path on either side may be distinctly correlated with the development of the behavior of the embryo up till the time when locomotion becomes perfectly established.

Some of the more general results of this method of study are: (1) the demonstration of the nature of the primary reflex arcs of the vertebrate nervous system, (2) the discovery of the adaptive nature of the early reflexes when considered from the phylogenetic point of view, (3) proof that the final common path of the most primitive reflexes is elaborated into the nervous mechanism of locomotion, (4) the explanation of the typical be-

havior of a vertebrate upon the basis of demonstrable reflex arcs, (5) a distinctive contribution towards a biological neurology.

*The Correlation of Structure and Function in the Development of the Nervous System* (illustrated): STEWART PATON, M.D. Introduced by Dr. A. C. Abbott.

*The Relation between the Physical State of the Brain Cells and Brain Function* (experimental and clinical): GEORGE W. CRILE, M.D., Ph.D.

*Life of Cells Outside the Organism* (illustrated): ROSS G. HARRISON, M.D., Ph.D. Introduced by Dr. A. C. Abbott.

*Heredity and Selection*: WILLIAM E. CASTLE, Ph.D.

*The Nature of Sex and the Method of its Determination* (illustrated): CLARENCE E. MCCLUNG, A.M., Ph.D. Introduced by Dr. George A. Pier-sol.

*Fever: Its Nature and Significance*: VICTOR C. VAUGHAN, M.D., LL.D.

It has been shown experimentally that fever is due to the digestion of proteins in the blood and in the tissues. Bacteria are living proteins. They get into the body and grow, converting the proteins of man's body into bacterial proteins. After a period of incubation the cells of the body pour out a ferment which digests and destroys the bacteria. In this process fever originates. In itself fever is beneficial. It is a manifestation of the attempt on the part of nature to destroy the invading organism. However, nature may overdo the matter, and fever per se becomes dangerous when it goes much above 105°. Any kind of fever, acute fatal, intermittent, remittent or continued, may be induced in animals by repeated injections of properly graduated doses of foreign protein.

*The Control of Typhoid Fever by Vaccination*: MAZYCK P. RAVENEL, M.D.

Vaccination against typhoid fever as practised to-day we owe to the researches of Dr. (now Sir) Almroth E. Wright.

It was tried for the first time on a large scale during the Boer war. Since that time it has undergone investigation by scientific boards in several countries. In the United States it was recommended by such a board in 1909. The results were so favorable that it was made compulsory for all officers and enlisted men under forty-five years of age in 1911.

The most striking results were obtained during the mobilization of troops in Texas in 1911. There were 12,801 troops in Texas, all vaccinated.

There was only one case of typhoid fever, occurring in a private of the hospital corps, who had not completed his immunization. The case was mild, and resulted in recovery. In 1898, 10,759 troops were stationed in Jacksonville, Florida, under very much the same conditions as regards climate, etc. Vaccination was not practised at that time. There were 2,693 cases known or believed to be typhoid fever, with 248 deaths. Wherever practised, very much the same story is told. The French troops in Morocco under most unhygienic surroundings have entirely escaped typhoid fever where vaccination was practised.

The method is an extension of the well-known bacterial vaccination discovered by Pasteur. It is now generally recommended for nurses in hospitals and those exposed to the disease.

In Wisconsin the State Laboratory of Hygiene sends out the vaccine free of charge to all physicians in the state. In more than three thousand vaccinations only two cases of typhoid fever have come to our notice; both of these cases mild and atypical.

The method has shown itself of great value in checking epidemics, and in the cure of typhoid carriers.

#### FRIDAY, APRIL 18—AFTERNOON SESSION

William B. Scott, Ph.D., LL.D., vice-president,  
in the chair

*Guatemala and the Highest Native American Civilization*: ELLSWORTH HUNTINGTON, M.A., Ph.D. Introduced by Mr. Henry G. Bryant.

Among the native civilizations of the western hemisphere that of the Mayas was decidedly the highest. Not only did they develop the arts of architecture and sculpture to a surprisingly high point, considering the fact that they had no tools of iron, but they were the only American race to evolve the art of genuine hieroglyphic writing. To-day the magnificent ruins of the later, decadent Maya period, dating about A.D. 1000, are relatively accessible, as they lie in the comparatively dry, open and well-populated strip which borders the peninsula of Yucatan on the north. The oldest ruins, however, those representing the period of highest development a few centuries after the time of Christ, are located in one of the most inaccessible, least explored, most unhealthy and most sparsely populated regions of America. The Guatemalan province of Peten, together with the immediately surrounding regions, where the greatest ruins are located, consists of a plain or low hills lying between the Atlantic Ocean on the east,

the Gulf of Mexico on the north and the high volcanic plateau of Guatemala on the west and south. It is to-day one of the worst possible environments for man. In the first place, it receives so much rain that it is covered for the most part with a dense tropical forest or jungle where the excessive moisture and rank growth of vegetation render it practically impossible to make clearings and practise anything but the most haphazard agriculture. In the second place the region suffers to a maximum degree from the disadvantages of a uniformly warm, moist, debilitating climate. And finally it is afflicted with the worst kind of tropical fevers which weaken and destroy white men and natives alike and render thousands of square miles practically uninhabited.

To-day Peten stands at the lowest point in the scale of American civilization. Close beside it the Guatemalan plateau with its drier, less debilitating climate, less dense vegetation, and relative absence of malarial fevers, is far in advance of it, although inhabited by practically the same race and governed by the same laws. Formerly the reverse was true; the plateau was, relatively speaking, only moderately advanced; that is, it was a provincial region, while the lowland was for many centuries the seat of a culture equal to that of the highest races of the eastern hemisphere before the days of Greece. In the last 1,500 years, more or less, there has evidently taken place a change of great magnitude. In explanation of this change three possibilities present themselves. First, the Mayas may have possessed a degree of energy and initiative and of resistance to fevers and to the debilitating influence of the torrid zone much in excess of that of any other known people. Second, in their day tropical fevers of the more destructive types may have been unknown in Central America; and, third, the climate may have changed. All three theories are probably true in part, but there is no independent evidence as to the first two. On the other hand, alluvial terraces and their relation to such ruins as Copan furnish strong independent evidence of climatic pulsations during the past 2,000 years. We are therefore led to conclude that although the Mayas were a remarkable people they did not of necessity excel all other races in their resistance to disease and in their power of overcoming the obstacles of a habitat—lowland forests in the moister portions of the torrid zone. In their day, apparently, the earth's climatic zones were shifted somewhat equatorward, so that in winter the conditions of the dry subtropical zone of high pressure and perhaps the

rainless fringes of our cyclonic storms prevailed in the country. The yearly dry season thus produced, probably prevented the growth of dense forests, made agriculture possible, greatly reduced the amount of disease and acted as a direct stimulant by relieving the deadening monotony of the almost unchanging moist heat. A relatively slight climatic change such as this would alter the physical environment of Peten from exceedingly unfavorable to relatively favorable, and would render the location of the highest native American civilization rational instead of almost inexplicable.

*Further Considerations on the Origin of the Himalaya Mountains and the Plateau of Tibet:*  
T. J. J. SEE, A.M., Ph.D.

*Dana's Contribution to Darwin's Theory of Coral Reefs:* WILLIAM MORRIS DAVIS, Sc.D., Ph.D.

It is fitting on the hundredth anniversary of Dana's birth to call attention to a significant contribution that he made many years ago to Darwin's theory of coral reefs, all the more because, although it has high confirmatory value, it has been strangely overlooked by most students of the coral island problem. Darwin, as is well known, explained barrier reefs by an upgrowth of the corals of fringing reefs during a slow subsidence of the central island on which they were established; but he did not offer any direct confirmatory evidence of the truth of his fundamental assumption of subsidence. Dana furnished independent confirmatory evidence of the assumption by pointing out that the central islands of barrier reefs are, as far as he had descriptions of them, characterized by embayed coast lines, precisely such as must result if they had subsided; all of their valleys are invaded by the sea and converted into bays. Darwin had noted this fact, but had not perceived its significance, probably because he did not understand that the embayments of a coast line are in nearly all cases formed by the submergence or drowning of preexistent valleys. Dana was the first observer in the world to bring forward this explanation, to-day everywhere accepted, and the first also to apply it to the central islands of barrier reefs. In recent years several Australasian observers have resurrected Dana's idea, and have found in it, as he did, a strong confirmation of Darwin's original theory.

*The Formation of Coal Beds:* JOHN J. STEVENSON, A.M., LL.D.

*Cambrian Fossils from British Columbia (illustrated):* CHARLES D. WALCOTT, Ph.D., Sc.D., LL.D.

Dr. Walcott gave illustrations of a very remark-

able and ancient fossil fauna discovered by him in the mountains of British Columbia, 2,000 feet above Field, on the Canadian Pacific Railway.

The fossils are most beautifully preserved and include such delicate forms as medusæ (jelly fishes), holothurians (sea cucumbers), finely preserved marine shells of various kinds and a large variety of crustaceans. Some of the latter are so perfectly preserved that the branchia, legs and alimentary canal are shown, and even in several forms the liver is so perfect that the ramifications of the tubes through it are reproduced by photography and thus illustrated by lantern slides.

Altogether over 80 genera of invertebrate fossils have been found from a bed not over 5 feet in thickness. They are all of marine origin and lived at a period when there were no vertebrates (fishes, reptiles, mammals) in existence.

*The Alleghenian Divide and its Influence upon Fresh-water Faunas:* ARNOLD E. ORTMANN, Ph.D., ScD.

Although it is well known that the Allegheny Mountains form a general boundary between the aquatic forms inhabiting their western and eastern slopes, particulars about the relations of the two faunas were missing. In fact, the fundamental facts, the actual faunas of the various streams, chiefly in the mountains, were unknown.

The writer furnishes first these facts for a number of aquatic forms of life, chiefly the fresh-water mussels, the Pleuroceridae and the crayfishes, covering the region from the New York-Pennsylvania state line to the northern boundary of Tennessee. The main results are, that the groups mentioned have not been transported over land to any extent, and consequently are apt to furnish evidence as to the former drainage conditions. The Allegheny Mountains have acted most of the time as an effective barrier to the dispersal of fresh-water life, surely so since the end of the Cretaceous. The Atlantic side received its fauna from the Interior Basin, but not across the mountains, but around their northern and southern ends. A few instances are known, where single species have crossed the divide, and these cases are found in two sharply-restricted regions: they are probably due to stream piracy.

*Neutralization and Elimination of Toxic Substances:* OSWALD SCHREINER, Ph.D.

*Progressive Evolution among Hybrids of *Ænothera* (illustrated):* BRADLEY M. DAVIS, A.M., Ph.D. Introduced by Professor John M. Macfarlane.

Certain cultures of hybrids between *Ænothera*

*biennis* and *Ænothera grandiflora* have presented in the second generation a high degree of progressive advance in flower size and in the size of the leaves and the extent of their crinkling. A hypothesis for such progressive evolution is offered by the Mendelian principle of recombination of factors for large size on the assumption of multiple factors for the dimensions of organs, but this hypothesis also demands the presence in the same culture of groups of plants containing the factors for small size. When in an  $F_2$  generation there is a considerable group of plants with flowers larger than those of the larger parent there should also be expected corresponding groups with flowers as small or smaller than those of the smaller parent. This follows on the Mendelian law of the conservation of factors by which the factors contained in an  $F_1$  hybrid must all come out in an  $F_2$  generation, provided that this generation is sufficiently numerous and that the formation and mating of gametes present no exceptional features. In  $F_2$  generations of about 1,000 and 1,500 plants, respectively, there were no groups of plants with flowers as small as or smaller than those of *biennis*, the small-flowered parent. There were thus no groups to balance the large proportion of plants with flowers larger than those of the *grandiflora* parent. The cultures as a whole presented a marked advance in flower size.

A similar situation was presented by the character of the foliage in certain  $F_2$  generations. The leaves throughout the mass of these cultures were much larger than those of the parents and generally much more crinkled. There was thus a marked progressive advance in leaf size with the absence of small-leaved groups of plants, and it is difficult to explain the results on strict Mendelian principles of segregation according to which groups in an  $F_2$  generation containing the factors for large leaf-size should be accompanied by corresponding groups containing the factors for small leaf-size.

There was in these  $F_2$  generations abundant evidence of segregation as shown in a range of variation far above that presented by  $F_1$  generations, but this range was between groups of plants with flower and leaf size much greater than those of the two parents. Thus the petals in the larger-flowered groups were 1 cm. longer than those of the *grandiflora* parent with petals 3.3 cm. long, and the flowers of the smaller groups were two or more times larger than those of the *biennis* parent with petals 1.3 cm. long.

Certain of the  $F_2$  generations presented classes

of dwarfs in proportions as high as 1:9 and 1:5.7. These classes were sharply separated from the mass of the cultures and there were no intermediates between the two groups. The high proportions suggest the 1:5 ratio which might be expected if two factors for size were present, each allelomorphic to its absence. Such a simple explanation, however, calls for the appearance of corresponding classes of giants to balance the dwarfs and for several other classes of plants of different sizes composing the mass of the cultures; such classes were not found. The dwarfs then present a puzzling phenomenon not readily understood on current Mendelian views of the segregation of factors governing size.

Admitting the complexity of the situation when such an extreme cross is made as that between *Oenothera biennis* and *Oenothera grandiflora*, there still appears to the writer sufficient reason in the data at hand to present the problems as material for reflection on the Mendelian theory of the stability of factors and the principles of their distribution unchanged in the organization of gametes. The question naturally arises whether the phenomenon of the progressive advance exhibited in the  $F_2$  generation of these hybrids as well as the formation of groups of dwarfs may not involve, as a result of the cross, the direct modification of factors for size.

*Climatic Areas of the United States as Related to Plant Growth* (illustrated): BURTON E. LIVINGSTON, Ph.D. Introduced by Professor John W. Harshberger.

This paper deals with that phase of plant geography which relates the distribution of the various forms of vegetation to climatic factors, a phase which is as important to scientific agriculture as it is to what is commonly termed pure science.

Following an introductory consideration of the nature of the problem to be dealt with and some remarks on the sort of means by which we may hope to obtain quantitative information upon the relation of plant growth to climatic conditions, attention is given to the subdivision of the United States into climatic areas more or less susceptible of quantitative definition. Climatic conditions, as far as they influence plants, must be considered mainly as two comparatively distinct groups of environmental factors. The first of these groups constitutes the moisture conditions, tending to furnish the plant with water or to withdraw moisture from its tissues. The second group, the temperature conditions, tend to increase or decrease the temperature of the plant body. As a primary

duration factor for the attempted integration or averaging of these climatic conditions, the length of the frostless season is introduced; for practically all animals and perhaps for most other plant forms in the United States, the conditions which are effective during the frostless season have far more influence on plant distribution than have those which are effective during the remainder of the year. Other time periods require attention, however.

From a somewhat thorough study of the climatic data which are at hand it appears that any two systems of isoclimatic lines, one system representing the geographical distribution of temperature conditions and the other representing that of moisture conditions, have a strong tendency to cross each other, thus dividing the country into many climatic areas, each one capable of quantitative description. The remainder of the paper concerns itself with a discussion of selected examples of these areas and of the natural vegetation which characterizes them. This line of study is in its reconnaissance stage and the results are quite tentative in their character.

*The Day of the Last Judgment*: PAUL HAUPT, Ph.D., LL.D.

The conception of the day of the last judgment is based on the idea of the day of the Lord in the Old Testament prophecies. Originally the judgment-day, resurrection and immortality referred to the Chosen People. The dry bones in Ezekiel xxxvii represent the Jewish nation in the Babylonian captivity. The so-called eschatological passages as well as the alleged Messianic prophecies have, as a rule, a definite historical background, but when the bills drawn on the future were not honored they were extended to doomsday.

The final chapter of the book of Joel does not contain an eschatological prophecy referring to the end of the world, but the confident prediction of an enthusiastic patriot expressing the hopes of the Maccabees for the near future. Nor does the last chapter of the book of Zachariah refer to the last judgment; originally it predicted merely a decisive victory of the Maccabees over their enemies about 140 B.C. and subsequent engineering improvements in and near Jerusalem.

The ideas of doomsday, resurrection and immortality are secondary, but Ernest Renan is right in saying that there is no lever capable of raising an entire people if once they have lost their faith in the immortality of the soul, and Dr. A. E. Garvey remarks: "He who lives for the ideals of truth,

beauty, goodness, lives not for time but for eternity."

*On the Character and Adventures of Máladora:*

MAURICE BLOOMFIELD, Ph.D., LL.D.

On Friday evening at the Hall of the Historical Society of Pennsylvania George Grant MacCurdy, A.M., Ph.D., assistant professor of archeology, Yale University, gave an illustrated lecture on "The Antiquity of Man in the Light of Recent Discoveries."

On Saturday morning at 9:30 o'clock an executive session was held in the hall of the society at which candidates for membership were balloted for. As a result of the election, the following new members were announced: *Residents of the United States*—George Francis Atkinson, Ph.D., Ithaca, N. Y.; Charles Edwin Bennett, A.B., Litt.D., Ithaca, N. Y.; John Henry Comstock, B.S., Ithaca, N. Y.; Reginald Aldworth Daly, Boston, Mass.; Luther Pfahler Eisenhart, Princeton, N. J.; George W. Goethals, Culebra, Canal Zone; William C. Gorgas, M.D., Sc.D., LL.D., Ancon, Canal Zone; Ross G. Harrison, A.B., Ph.D., M.D., New Haven, Conn.; George Augustus Hulett, Princeton, N. J.; Clarence E. McClung, A.M., Ph.D., Swarthmore, Pa.; John Dyneley Prince, Ph.D., Sterlington, N. Y.; Samuel Rea, Sc.D., Bryn Mawr, Pa.; Henry Norris Russell, Ph.D., Princeton, N. J.; Charles Schuchert, New Haven, Conn.; Witmer Stone, A.M., Philadelphia. *Foreign Residents*—Sir Arthur John Evans, D.Litt., LL.D., F.R.S., Oxford, England; Sir Joseph Larmor, D.Sc., LL.D., F.R.S., Cambridge, England; Arthur Schuster, Sc.D., Ph.D., F.R.S., Manchester, England.

SATURDAY, APRIL 19—MORNING SESSION

Edward C. Pickering, D.Sc., LL.D., F.R.S., vice-president, in the chair

*The Potassium, Phosphorus, Nitrogen Cycles:*

CHARLES E. MUNROE, Ph.D., LL.D., F.C.S.

*An Ammonia System of Acids, Bases and Salts:*

EDWARD C. FRANKLIN, M.S., Ph.D.

*Some Unsolved Problems in Radioactivity* (illustrated): WILLIAM DUANE, Ph.D. Introduced by Professor Arthur W. Goodspeed.

More than thirty different substances are known to be radioactive in much the same way that radium is radioactive. Most of these substances disappear more rapidly than radium does, only five of them having an average life greater than that of radium, which is about 2,000 years. The average lives of the others vary from a fraction of a second to 24 years.

The law according to which these substances disappear is the same for all of them. It may be stated thus: The rate at which any substance disappears is proportional to the quantity of that substance present, and absolutely independent of all conditions of temperature, pressure and state of chemical combination, etc. This is a very simple law, and the mathematical equations that can be deduced from it probably represent the facts as accurately as any known equations represent facts in other branches of science.

Looked at from another point of view, this law is not very easy to understand. Let us take a particular example. Suppose we have a quantity of that substance called radium emanation. The law applied to this quantity of radium emanation means: that certain atoms of emanation will explode and transform themselves into radium *A*, during the next few seconds, whereas other atoms of this same emanation will remain emanation atoms for a long time, and will not transform themselves for months to come. The question is this: How can atoms which are physically and chemically similar to each other, yet be so different that some of them will disappear immediately and others not for a long time. The explanation of this probably lies in the internal structure of the atom and not in external causes, for external conditions have no known effect upon the phenomenon.

The second unsolved problem to which I wish to call your attention is connected with the rays given off by the substances during their transformations. Some substances produce what are called  $\alpha$ -rays and some  $\beta$ -rays, and other substances produce both  $\alpha$ - and  $\beta$ -rays. If a particular substance produces  $\alpha$ -rays, one and only one  $\alpha$ -particle is ejected during the transformation of each atom of that substance, and the same is true of the  $\beta$ -rays. The  $\alpha$ -particles from the same substance all have the same velocity. For instance, the  $\alpha$ -rays from radium *C* all have a velocity of  $2.09 \times 10^9$ . The  $\beta$ -rays, however, from the same substance do not all have the same velocity. Each  $\beta$ -particle has one of a certain number (8 or 10) of well-defined velocities. For example, each  $\beta$ -particle projected from an atom of radium *C* must choose one of a certain set of velocities lying between  $1.85 \times 10^{10}$  and  $2.99 \times 10^{10}$  cm./sec.

It is difficult to understand why the explosion of an atom, say of radium *C*, which, so far as known, is just like the explosion of every other atom of radium *C*, and produces an  $\alpha$ -ray of a

certain definite velocity, should produce a  $\beta$ -ray, having now one velocity and now another. Several attempts to explain this phenomenon have been made, but without complete success. Doubtless the true explanation must be sought for in the internal structure of atoms, as in the first problem mentioned above.

The third problem I will mention has to do with the  $\gamma$ -rays. It is known that the  $\gamma$ -rays are intimately connected with the  $\beta$ -rays, each type of ray being capable of producing the other, but the exact relationship between them is not very well understood. The particular question, however, that I wish to bring up is this: is the  $\gamma$ -ray a wave form spreading out as sound waves do from their source, or is it of corpuscular nature resembling the sparks projected from an exploding rocket? The fact that the velocity of the  $\beta$ -ray, which the  $\gamma$ -ray is capable of producing, does not depend upon the distance from the source of the  $\gamma$ -ray to the point at which the  $\beta$ -ray is produced seems to indicate that the latter hypothesis is correct.

The explanations of these phenomena are intimately connected with the theories of interaction of matter and electricity, and it is interesting to note that the theory, which in modern times has been of most use, the theory according to which both matter and electricity are of atomic nature, was first promulgated about 150 years ago in our own city of Philadelphia by no other than Benjamin Franklin himself, the founder of this society.

Perhaps the most important radioactive problem of practical value upon which scientists are working to-day is the effect produced by the various radiations on human tumors. Photographs were shown illustrating the results obtained in France and Germany by subjecting small superficial cancers to the action of the rays. It must be remembered that the problem of curing deep-seated malignant tumors is by no means solved.

*Some Diffraction Phenomena; Superposed Fringes:*

CHARLES F. BRUSH, Ph.D., LL.D.

Diffraction fringes, as usually seen, are not affected by thickness or contour of a smooth, straight diffracting edge, as pointed out by Fresnel. The author finds, however, that when the fringes outside the shadow are observed within one or two millimeters from the diffracting edge, by means of a microscope, their brightness and sharpness are very greatly affected by the character of the edge. For instance, a cylindrical edge of several millimeters radius gives vastly brighter fringes than a sharp razor edge. He finds this is due to super-

position of many diffraction fringe patterns which are nearly in register. They are believed to be formed by many contiguous elements of the cylindrical surface, each acting as a diffracting edge and producing its own fringes. The author further shows that the so-called "single mirror interference fringes" of Lloyd may be produced under conditions which preclude reflection, and which at the same time make it obvious that they are formed by superposition of diffraction fringes.

*Matter in its Electrically Explosive State:* FRANCIS E. NIPHER, A.M., LL.D.

*New Investigations on Resonance Spectra:* R. W. WOOD, Ph.D.

*Application of Recent Studies on the Origin of the Earth's Magnetic Field to the Possible Magnetic Fields of Rotating Bodies in General* (illustrated): LOUIS A. BAUER, Ph.D.

*The Determination of Visual Stellar Magnitudes by Photography:* EDWARD C. PICKERING, D.Sc., LL.D., F.R.S.

Ordinary photographic plates are most sensitive to blue light, while the yellow rays are those that affect the eye most strongly. Accordingly, blue stars appear brighter and red stars fainter in a photograph than to the eye. Isochromatic plates are, however, manufactured which are very sensitive to yellow light. If a yellow screen is interposed the blue light is cut off and red stars appear even brighter, relatively, than they do to the eye. By using a thin yellow screen which cuts off only a portion of the blue rays it is possible to obtain plates having the same color index as the eye. To fulfil this condition several blue and several red stars have been selected near the North Pole. Photographs are then taken with different screens until one is found which gives images of the same relative brightness as the naked eye. With the 16-inch Metcalf Telescope at Harvard, stars as faint as the twelfth magnitude may be photographed in this way with an exposure of ten minutes. With an exposure of two hours, stars can be photographed about as faint as they can be seen with a telescope of the same size. On a perfectly clear night a photograph is taken of the North Pole with exactly 10 minutes' exposure, then similar exposures on four different regions, then a second time on the North Pole, on five other regions, and a third time on the North Pole. The twelve plates are developed together and various precautions taken to secure uniform results. The magnitudes of numerous stars near the North Pole have been measured with great care and the mag-

nitudes of stars on the other plates can thus be determined on the same scale.

*Some Problems in Connection with the Milky Way as shown by Photographs with a Portrait Lens:*  
EDWARD E. BARNARD, Sc.D., LL.D.

*The Spectroscopic Detection of the Rotation Period of Uranus:* PERCIVAL LOWELL, LL.D., and V. M. SLIPHER, Ph.D.

By means of the spectroscope, it is possible to measure the speed of approach or recession of a luminous body; for the lines of the spectrum are shifted toward the violet or red in proportion as the body moves toward or from the observer. Hence, if the image of a rotating planet be so thrown upon the slit of the spectroscope that one end of the slit is illuminated by light from the approaching side of the planet and the other end by light from the receding side, the lines will be tilted through an angle which measures the speed of rotation.

In this way, from spectrograms obtained at the Lowell Observatory in 1911, the authors determined the rotation of the planet Uranus about its axis to take place in ten hours and fifty minutes, in a direction opposite to that of the rotation of the planets nearer the sun. Thus, for the first time, an authentic determination of the rotation of this planet has been made by a direct method.

*On the Spectrum of the Nebula in the Pleiades:*  
V. M. SLIPHER, Ph.D.

Two photographs of the spectrum of the faint nebula near Merope, a bright star in the Pleiades, were obtained in December, 1912, with a slit spectrograph attached to the Lowell 24-inch refractor. The two plates were exposed five and twenty-one hours, respectively. They agree in showing a continuous spectrum crossed by the dark lines of hydrogen and helium, the spectrum of the nebula being a true copy of that of the brighter stars of the Pleiades. The light of the nebula is thus shown to be of stellar origin. As it seems improbable that a mass of stars, all of the same spectral type as the Pleiades, should so group themselves behind the Pleiades as to give the appearance of a nebula, the author believes it more probable that the nebula consists of diffused material surrounding the stars and shining by reflected star light.

This is the first successful observation ever published upon the spectrum of this faint nebula.

*Eclipsing Variable Stars:* HENRY NORRIS RUSSELL, Ph.D. Introduced by Professor William F. Magie.

*Progress of New Lunar Tables:* ERNEST W. BROWN, M.A., Sc.D., F.R.S.

SATURDAY, APRIL 19—AFTERNOON SESSION

Edward C. Pickering, D.Sc., LL.D., F.R.S., vice-president, in the chair

Presentation of a portrait of William W. Keen, M.D., LL.D., president of the society, by Joseph G. Rosengarten, A.M., LL.D., on behalf of the subscribers.

Vice-president Pickering accepted Dr. Keen's portrait on behalf of the society.

The rest of the session was occupied by a symposium on Wireless Telegraphy and Telephony, during which the following papers were read:

*Radiated and Received Energy:* LEWIS W. AUSTIN, Ph.D. Introduced by Professor William F. Magie.

Mathematical theory indicates that the energy radiated from a radiotelegraphic antenna proportional to the current in the sending antenna, to the height of the sending antenna, to the height of the receiving antenna, inversely proportional to the wave-length and inversely proportional to the distance between the two antennas. Since the loudness of signal is proportional to the square of the current in the receiving antenna, the signal falls off as the square of the distance between the two.

This law has been verified by the experiments made by the United States Navy Department between the new high-power station at Arlington and several other stations situated in and near Washington.

Observations at distances over 100 miles show that in addition to the diminution in intensity of signal with the distance, there is an absorption either in the atmosphere or ground such that at a distance of 1,000 miles over salt water with a wave-length of 1,000 meters the received current is only approximately 1/25; that is, the received signals are reduced to about 1/600 of what they would have been had there been no absorption.

The absorption decreases as the wave-length is increased, so that for communication over great distances, long waves, 4,000 to 7,000 meters in length, are used, while for short distances of a few hundred miles short waves are better since they are radiated more energetically. These facts apply to daylight communication only, which is in general regular, night ranges, though greater than day, being freakish and uncertain. The absorption over land is much greater than over water, especially for the shorter wave-lengths.

In recent tests between the Arlington station and the scout cruiser *Salem* on its voyage to Gibraltar and return, messages were received from Arlington in the day time on the *Salem* up to a distance of 2,100 nautical miles, and at night as far as Gibraltar.

A comparison was also made of the action of two types of sending sets, one being the regular spark sending set and the other set in which the waves are produced from an electric arc. It has been claimed that the continuous waves emitted by the arc are less absorbed than the broken-up trains of waves produced by the spark. Up to 1,000 miles no difference in the absorption was observed, but at 2,000 miles the observations indicated that the received arc energy was relatively four times greater than that of the spark.

*Resonance in Radiotelegraphic Receiving Stations:*  
GEORGE W. PIERCE, A.M., Ph.D. Introduced by  
Professor Arthur W. Goodspeed.

*A New Form of Resonance Circuits:* MICHAEL I. PUPIN, Ph.D., Sc.D.

*The International Radiotelegraphic Conference of London and its Work:* ARTHUR GORDON WEBSTER, Ph.D., LL.D.

The great development of wireless telegraphy and the embarrassment arising from interference in communication and the refusal of different companies to transmit messages at sea led to the necessity of international control, and brought about the Conference of Berlin in 1906. It was then decided that these conferences should be periodic, and the second one was held in London in June and July, 1912. The United States sent a delegation of twelve members, representing various departments, including the army, navy and commerce and labor. The working of the conference was described, and the strong personnel of the representatives of the more than forty countries represented. All governments except that of the United States, owning the telegraphs, are able to exercise absolute control, and were represented by high officials of their post-office and telegraph administrations, as well as by military officers.

The work of the conference was concerned mainly with the questions of prevention of interference between different stations, of increasing the safety of vessels and of the prevention of abuses in improper competition, the latter being a matter in which this country was not interested. The question of interference occupied the major

part of the time of the conference. Two standard wave-lengths were adopted, which were made obligatory, so that there could be no excuse for not hearing messages. The amount of power to be used was limited, so that it should not be in the power of one station to drown out others. On account of difficulties in crowded waters like the English channel, surrounded by several nations, strict rules of precedence were established and the multiplication of useless calls was restricted. Attempts to overreach one country by powerful stations belonging to another caused considerable feeling and were regulated.

In the interest of security, all stations are to be licensed by their governments. Operators must also be licensed, and shall be of two classes, according to proficiency. Operators of the second class are to be permitted only on small ships, and as substitutes on those having one operator of the first class. The wireless stations are put under the authority of the officer in command of the ship. On passenger ships there must be a special emergency plant capable of operation independently of the ship's power, and strong enough to reach eighty miles. Such stations must listen for distress calls for ten minutes of each hour. High-power shore stations must periodically cease transmitting, in order not to interfere with distress calls. Distress calls are given absolute preference. The transmission of meteorological news is facilitated by giving it priority, when sent to certain designated designations.

The author expressed the opinion that in spite of all that had been done, before the next conference, to be held in Washington in 1917, wireless traffic would have so increased that much more stringent regulations, as well as improved methods of tuning, would be necessary.

A general discussion followed, led by Professor Elihu Thomson.

At the annual dinner on Saturday evening, at the Bellevue-Stratford, over one hundred members and guests were present, the toasts being responded to as follows:

"The Memory of Franklin," by His Excellency the French Ambassador.

"Our Guests," by Professor Arthur Schuster.  
"Our Institutions of Learning," by Professor A. G. Webster.

"The American Philosophical Society," by Mr. Hampton L. Carson.

## THE GRAMERCY-PRECISION BALANCES

---

*Made Entire of Magnalium      For Students' Use and Technical Purposes*

---

The unsightly appearance of ordinary students' balances, with wooden base and lacquered metal pillar, beam, pans, etc., after they have been in the laboratory for a short time, subjected to acid and other laboratory fumes, has made the Gramercy Precision Balances meet with immediate favor in educational and industrial laboratories throughout the world.

The balances are made entirely of magnalium, and lacquered with a durable colorless substance. They are light in weight, most durable, and elegant in appearance.

**The prices are very moderate.**

*Descriptive pamphlet on request*

## ON THE CULTIVATION OF THE CLINICAL SCIENCES OF DIAGNOSIS AND THERAPY<sup>1</sup>

IN preparing this address some weeks ago, I had written the statement that the membership of this association had fortunately been spared by death from any diminution in its numbers during the past year; shortly before this meeting, however, the association has suffered the loss of two of its original members—Dr. John S. Billings and Dr. Francis P. Kinnicutt, and one of its associate members, Dr. Hugh A. Stewart.

We now enter upon the work of the twenty-eighth annual meeting. Each annual session begins with an address from the president, by by-law limited to half an hour, and by custom including, first, an expression of appreciation of the honor of presiding over the assembly, and, second, suggestions for the promotion of the welfare of the association and, more especially, for the adaptation of its functions to the ever-changing conditions of American medicine.

My first duty is, then, to give thanks. The president of the association would indeed be guilty of ingratitude were he to omit to thank his colleagues for the honor and distinction they confer upon him by his election. Even though the choice comes automatically in serial sequence to members of the council, to be chosen as this officer is an honor which an ambitious physician might well be willing to look forward to as a possible culminating event

<sup>1</sup>Address of the president before the Association of American Physicians, Washington, May 6, 1913.

in a life of distinguished service in the profession. In the present instance, the selection has obviously been made rather as an encouragement to future work than as a reward for past performance; I can only be grateful for the generosity shown me and for the powerful stimulus to worthy effort which such confidence begets.

Turning now to the work of the association itself, it is plain that the great changes which have taken place in medicine since the foundation of the society in 1886 have modified old needs as regards associations and created new ones. Our attention has been called repeatedly to the changing needs by our presiding officers, most emphatically, perhaps, by Dr. Councilman in 1904 and by Dr. Adami last year.

Methods of medical education in the United States have passed through a veritable revolution. The proprietary medical schools, useful enough in their time, became insufficient and have been largely replaced by medical departments of universities, privately endowed, or aided by the states. The laboratory disciplines, under the stimulus of the great advances of biology, chemistry and physics in the second half of the last century, have experienced an unprecedented expansion, and the army of medical teachers and investigators has thus been recruited by a series of new battalions, made up of men trained in pathology, bacteriology, physiology, psychology, physiological chemistry, pharmacology, anatomy, histology and embryology. Many of the teachers and investigators in these purely laboratory branches are men limited in clinical experience to their undergraduate training; some of them, indeed, have entered upon a career in these fundamental medical sciences, after a preliminary apprenticeship in laboratories of biology or chemistry without taking even an undergraduate

course in medicine. Meantime a high degree of specialization has been taking place also in the clinical branches. With the advent of anesthesia and asepsis in surgery came the opportunity for unexpected divisions of labor in surgical fields, while the introduction of instruments of precision, and of the methods of pathology and bacteriology, of biology and chemistry, in the work of internal medicine led to the intensive development, by skilled workers, of its various special domains.

One result of the almost explosive progress in the purely laboratory branches, has been to place the clinical subjects, and especially internal medicine, in almost an embarrassing situation. Internal medicine is, of all the biological sciences, the one to which the largest number of other sciences contribute facts for application. Internal medicine is usually designated as one of the "applied sciences." But all the sciences, with the possible exception of mathematics, are largely "applied science." Thus, physics consists in part of applications of mathematics; chemistry of applications of mathematics and physics; biology of mathematics, physics and chemistry; physiology of physics, chemistry and biology, and so on, with avalanche-like increase of the sciences to be applied, until internal medicine is reached with all the laboratory subjects offering it their aid.

Now each of these sciences, though largely applied science, is compelled to grow in its own way; each science is creative and has to devise methods of its own; even when a new fact in a science basal to it is applicable, the application has actually to be made. Take physiology as an example. A new discovery in physics, or in chemistry, does not enrich physiology until physiology makes use of it; indeed it may long lie unapplied since its fruitful application in physiology involves a physi-

ological research. The number of physical, chemical and biological facts as yet unapplied to physiological problems is so enormous, and the number and powers of physiological workers relatively so limited, that progress, though rapid, in physiology, can by no means keep pace with that of its underlying sciences, no matter how desirable this may seem.

The clinical subjects are similarly situated though in transcendent degree. It is almost a wonder that the clinician is not suffocated by the physical, chemical, biological, anatomical, physiological, pharmacological, pathological, parasitological and psychological facts which are being heaped upon him with clamor for their application. Moreover, the facts have arrived so suddenly that they find the clinician, in many instances, unable to understand them, much less to apply them. Certain chemical, physiological and anatomical facts the clinician of the last generation had, indeed, trained himself to apply by study in the post-mortem room, in the histological laboratory and in the laboratory for urinalysis. But recently, and all at once, the air has become thick with applicable facts of the most diverse origin, and only the younger clinicians have had opportunity for securing a training permitting of an understanding of even a part of them.

For some years past, students have been entering the clinics for instruction after three or four years of education in the methods and facts of the basal sciences from physics to pathology. They have been surprised to find, in many instances, their clinical teachers relatively unacquainted with the present-day content of the laboratory disciplines, and have often been astonished at the delay in attempting to apply in clinical studies facts of those laboratory branches which seem to them

obviously applicable to the work of diagnosis and therapy. Such personal observations by students working in the clinics have been a sharp spur to clinical men, and have undoubtedly gone far toward accelerating the application of laboratory facts and methods in the study and treatment of the sick. At times, of course, criticisms have been too severe or unjust. Students are prone to be harsh critics; their "young hot blood tingles to be up and doing"; often they know little of the circumstances which delay progress. In certain regrettable instances students may even have been led by a zealous but ill-informed pre-clinical teacher to believe that the workers in the clinical branches are not to be regarded as "scientific," but rather as "merely practical" men. This is an attitude occasionally assumed—happily less often now than a few years ago—by representatives of various sciences to all sciences to which they contribute facts for application, that is, to all sciences except those which are basal to their own. I can recall the time when an occasional teacher of physics, or of chemistry, hinted that the representatives of physiology or of physiological chemistry were amateurish or unscientific because the work in these branches is subject to conditions often inconsonant with profitable measurement in dynes or with graphic representation of stereochemical conceptions. But the older may well profit from the criticism of the younger, even if it be arrogant or unjust. The veteran, when taken to task by the recruit, may be amused, but if wise, instead of being offended, he will listen and will try to rejuvenate himself. In any case, he will rejoice in the vigor and optimism of the youth, and a part of his reward will lie in the consciousness of helping to train a group of successors who will surpass him.

It has been interesting to observe the attempts which have recently been made more fully and rapidly to utilize the new knowledge in the underlying sciences for the furthering of the work of diagnosis and therapy in the clinics. On the one hand, the older clinicians have heroically endeavored to acquaint themselves with the new facts as they have appeared; and they have hastened to surround themselves in their wards and in the clinical laboratories with younger men, trained in the newer laboratory methods, men who could aid them in the work of clinically applying the new facts. And, on the other hand, several universities have recently appointed to important clinical positions men who have been trained predominantly in the laboratory branches and who have made their early reputation in pathology, physiology, anatomy or chemistry, rather than in the clinical sciences. In these instances, we see two methods used to overcome a great difficulty and both are laudable. Each of them has led to advances in clinical teaching and research, but each of them is subject to obvious disadvantages. In the one instance, the clinical problems may be in the foreground, but insufficient personal acquaintance with the newer fundamental facts to be utilized limits vision; moreover, the lack of machinery for the utilization of the newer knowledge hampers the organization of diagnostic and therapeutic investigation. In the other instance, there is a real danger of an underappreciation of the nature, significance and scientific importance of the problems of diagnosis and therapeutics as such; the clinical appointee especially when untrained, or only slightly trained, in clinical work, and previously nursed in a fosterage, perhaps unfamiliar with, or even mildly disparaging of, the work of the clinic and of clinicians, may feel actually

ashamed to work at the bedside and in the laboratory at truly clinical problems, feeling that his former colleagues, to whom he may owe his appointment, will regard him as a scientific clinician only when he avoids researches bearing directly upon diagnosis and therapy and devotes his energies to the solution of non-clinical problems, the attack on which properly belongs to the laboratories of pathology, physiology or chemistry.

The situation is gradually righting itself. The non-clinical scientists realize better than they did what clinical work is and should be, and that workers in clinical branches should not be expected to leave their own fields to conduct other researches any more than the clinician can expect the anatomists or the physiological chemists to solve either the diagnostic and therapeutic problems of the clinic or the fundamental problems of physics and mathematics. All are acknowledging that the problems of diagnosis and therapy are tasks set by the patients themselves, that these living patients are, primarily, the objects of study of the clinical scientist. For this study a fine imaginative vision—properly schooled and rigidly controlled—is desirable. Patients must, in each generation, be looked at with fresh eyes, intellectualized partly by accurate training in the most recent clinical technique, partly by previous education in the methods, facts and hypotheses of the non-clinical sciences. It is gratifying that clinical men themselves, including those with extended training in one or more of the non-clinical sciences, are, more than ever before, recognizing the worth and dignity of diagnosis and therapy as sciences *per se*—that is to say, as bodies of knowledge to be increased, not merely as arts to be practised—sciences to be cultivated for their own sake as intensively, as proudly, and as enthusi-

astically as are the more basal sciences. And this is why clinical men are seeing to it that provision is made in the clinics themselves, not for the presence of patients only, but also for elaborate machinery for investigating them; they are demanding and equipping in each clinic a number of laboratories in which physical, chemical, physiological, pharmacological, bacteriological, psychological and other methods and facts can be directly applied by trained men in the diagnostic and therapeutic inquiries to which the conditions existing in the patients actually before them lead.<sup>1</sup> And, in addition to the more permanent staff, they are taking with them to the bedside and to the adjacent experimental laboratories of the clinic groups of medical students, trained in the basal medical sciences and making them responsible for the large amounts of routine work of which these students are capable while they are acquiring their early clinical experiences. To obtain proper facilities for clinical study and especially the multiple laboratories manned by skilled workers necessary in each clinic, not only will much money be required, but also an awakening of the understanding of the clinical men themselves, of non-clinical medical scientists and of hospital superintendents and trustees to the need. By many it is still thought that the laboratories of the non-clinical sciences can be called upon to do the laboratory work of the clinical sciences. By others, and especially by the superintendents of general hospitals (who are forced rigidly to limit the expenditure of money), the fallacy is still cherished that a "general clinical laboratory" in the hospital can best do the work of all the clinics for them. This, it seems to me, is a grave error. I am convinced that nothing short

of multiple special laboratory divisions *for the direction of which each clinic is itself actually responsible*, will ever satisfactorily supply the needs. Any other arrangement will emasculate the individual clinics and paralyze research in diagnosis and therapy. It was for a precisely similar independence for physiology that Purkinje had his great struggle about the beginning of the last century. The university faculty, and the university Kurator put great obstacles in the way. They did not see why physiology should not use the other laboratory (anatomy) for the work. The Kurator sarcastically asked "where will it lead to, if every scientific branch demands its own laboratory?" Thanks to Purkinje's clear vision and his persistence, and through the influence of Goethe and Alex. v. Humboldt, physiology finally got its independent institute. Von Ziemssen recognized a similar need for the medical clinics and demanded a "clinical institute" for teaching and laboratory researches in addition to his hospital wards. Only after such salutary conditions as those referred to have been realized in the clinics, and have been maintained there for a time, can we hope to breed a generation of clinicians in any way approaching the next necessary and realizable type—a type resulting from the fusion of training in accurate clinical observation with training in the solution of clinical problems by experimental work in the laboratory. The goal stands clearly in the view of those of us who are familiar with the present conditions and are ambitious for the advance of clinical knowledge. That this goal is being rapidly approached should be a consolation to the generation of clinicians chafing under the limitations of the period through which we are passing, more than one member of which has felt keenly the truth of the adage that "the

<sup>1</sup> Cf. "The Organization of the Laboratories in the Medical Clinic," *Johns Hopkins Hospital Bull.*, 1909, XVIII, 193-198.

man who rings the bell can not march in the procession."

The state of affairs to which I have referred has, to a certain extent, been reflected in the membership, and in the programs of the meetings, of this association. In 1886, the membership was made up chiefly of clinicians with a sprinkling of laboratory workers. In 1899, of 118 members, some 18 were pure laboratory workers who saw no patients at all. At present of 131 members, some 32 are pure laboratory workers who do not see patients, and many more are largely engaged in experimental work. Of the associate members, from whom our new members are in the near future to be drawn, at least one third are men who do not study patients but are engaged entirely in laboratory teaching or research.

A glance over the program of the meeting of 1899 shows that three non-clinical and twenty-seven clinical papers were presented. Last year, the program listed some thirteen non-clinical and some forty-six clinical papers. Our program this year includes some fourteen non-clinical and some fifty-one clinical papers.<sup>2</sup> A large proportion of the papers classed as clinical are reports of combined bedside and laboratory work. Now, on the whole this must be regarded as a very gratifying showing, illustrating, as it does, the great expansion in our clinics of work by experimental methods, as contrasted with work by more purely observational and statistical methods.

None welcomes, nor confides in, the experimental method more, perhaps, than I, but the observational method also deserves ever new application in clinical work. Is it not conceivable that we may actually retard progress in diagnosis and

therapy if we center investigation in our clinics and in their laboratories upon problems far removed from the conditions observable in the sick? May it not be desirable to plan that the experimental work in the clinics shall, for the most part, bear directly upon the problems of diagnosis and therapy (of course, in a wide sense, including etiology, pathogenesis and prognosis), and to arrange that the more fundamental physiological and experimental pathological inquiries be relegated to those laboratories, the particular business of which is to advance the sciences of general physiology and general pathology. Unless clinical men jealously guard their time, their interest, their energies and their materials in order to devote them to the advance of the clinical sciences, the progress of diagnosis and therapy must be slowed. Not that a clinician may not become so interested in pathology, physiology or physics as to make it justifiable for him to leave the clinic and occupy a non-clinical post. The clinics can only be proud to send occasionally a Helmholtz to physiology, as chemistry may be glad to contribute an Ostwald to philosophy. A man must go where his cerebral cortex leads him, be it from physics to physics, as in Helmholtz's case, or from crystallography to therapy, as in Pasteur's. Moreover, even in truly clinical investigation there will often be non-clinical by-products of great scientific value to which there can be no objection provided the main product corresponds to the aims of the clinical sciences. But, at this time, it would seem important to emphasize that researches in general physiology and in general pathology, valuable and desirable as they are for the progress of the medical sciences, as a whole, pertain to a field other than that which the clinics themselves should predominantly cultivate. May I illustrate by an analogy? Were our physiologists

<sup>2</sup>In making this arbitrary division into clinical and non-clinical papers I am guided by the direct relationship of the topic to the diagnosis and treatment of disease in human beings.

ogists to devote their time chiefly to the inquiries now pursued in the university laboratories of physics and chemistry to the neglect of their own physiological studies, the science of physiology would undoubtedly suffer. Now, none the less will scientific clinical work suffer loss if the men who are presumably cultivating the clinical sciences of diagnosis and therapy overlook their own legitimate problems, neglecting their clinical material to dissipate their time, and their energies, in the general or special non-clinical inquiries which properly belong to the more fundamental laboratories. The Wassermann reaction may be primarily worked out in a non-clinical laboratory, but the determination of its real significance for the diagnosis and treatment of disease demands, subsequently, long years of clinical research. Salvarsan may be made, and its spirilloccidal power tested, in experimental non-clinical laboratories, but its application and value in the treatment of the different forms of syphilis are problems upon which the clinics have only begun to work—problems the full solution of which may be slow in following upon the initial non-clinical investigations.

And this brings me again to our membership and the programs of our meetings. The mingling of clinicians (who study patients and who do experimental work in laboratories on clinical problems) with non-clinical experimental workers is stimulating, I believe, to both and *I trust that this association will always contain both*. Certainly, our non-clinical members have been and now are the very flower of our association. It must be remembered, however, that the anatomists, the physiologists, the biological chemists and the pathologists and bacteriologists now have their special societies, but that practitioners, teachers and investigators of internal medicine have

their principal representation in this association, and it has always been taken for granted that this association is mainly, though not exclusively, a society for workers in internal medicine (in the broad sense). In selecting new members, ought we not always to keep this main function of the association in mind?

Again, may we not do well to pay close attention to this main function in making up the programs for our annual meetings? There is a wide-spread and growing feeling among our members that the farther removed a paper is from the examination and treatment of patients, the more acceptable it is for the program. Able clinical men have told me that they find some of the papers presented at the meetings too far removed from the fields of diagnosis and therapy to be interesting or even intelligible to them. "Those who read these papers speak to us as in a foreign language" is a complaint I have more than once heard. Such a difficulty can not, of course, with a mixed membership, be wholly overcome. But something could, it seems to me, be done to remedy what careful consideration indicates is a real detriment to the fullest success of our meetings. Better suggestions than mine will, I hope, come from other members, but two possibilities occur to me. First, might we not, while accepting some papers in general physiology and general pathology, urge that they be of a character likely to enlist the interest of clinicians and that they be presented in a form easy to understand by men who have not worked upon the special subjects with which they deal; papers in general pathology and physiology of different content might better be presented in the societies of the physiologists and pathologists. Secondly, may it not be helpful to arrange the papers on the program in groups in some such way as that adopted

this year; an individual member could then attend particular sessions, or all sessions, according as his interest and activities are specialized, or more general. A glance at this year's program shows the broad scope of the combined interests of the members of this association; and this scope is sure to become still broader as internal medicine grows and specialization in its various subdivisions increases. Thus, before long, the problems of "social medicine" are likely to engage us more than they do now. And I should like, in closing, to refer for a moment to this topic. Society at present tries, for its own welfare, to educate all citizens of the state. It may soon decide to try also to maintain the health and efficiency of all. Should society so resolve, a great extension of the municipal, state and federal medical services would become necessary to prevent disease; and the present method of treating patients at their homes would, in all probability, be largely replaced by hospital treatment. And if health should come to mean more than mere existence without outspoken physical disease—to include an abundant vitality, the capacity for joyous activity and for successful adaptation to the environment—then society, to maintain the health of its members, would have to see to it that the children born inherit bodies capable of normal responses to environmental stimuli, and further, that the various environmental stimuli to which individuals are exposed are beneficial to them and not too injurious. Such an ideal campaign for health seems at present a mere dream. But some dreams are prophetic forerunners of reality, and if we are to judge of the future by certain signs in the present, say by the institution of the *Krankenasse* in Germany and by the movement toward a national medical service as advocated by Lloyd George in Eng-

land, it may not be long before we shall, in this country, too, be taking some important steps forward in "social medicine." And when the time for this is at hand, we can be sure that this Association of American Physicians will be ready to throw its influence in the direction most helpful to society as a whole.

LEWELLYS F. BARKER

BALTIMORE, MD.

#### THE MEANING OF GRADUATE STUDY<sup>1</sup>

It was a pleasure to me to accept the invitation tendered through your vice-president to appear before you to-night to speak on "The Meaning of Graduate Study." That it is important to every member of this club to have an adequate conception of this matter is obvious, and I shall not take time to emphasize this fact. I should like to say, however, by way of preliminary, that it is also vital to the university and to the state that both you and all the people of the state should be clear and accurate in your judgment as to the true nature and character of graduate work. On this depends, to a large extent, the success of the university and the measure of service which it may render to its constituency. I hope that the way in which your graduate study is thus vitally related to the university and to the community at large will appear with appropriate emphasis before I have done speaking.

We shall best avoid mutual misunderstanding if I state at the outset the answer which I have in mind to the question, "What is graduate study?"

In the first place it is not a further extension of undergraduate study. It is something different, not merely in degree, but rather in kind. The change from undergraduate to graduate work should be as marked as that from the high school to the university. On passing from the lower to the higher the student goes into a new atmosphere. He finds what is to him a novel attitude and point of

<sup>1</sup> Address to the Graduate Club of Indiana University, December 10, 1912.

view. He begins to look at science and the whole body of knowledge with anointed eyes, and presently the entire structure assumes a new aspect. The student is to be congratulated if this is accompanied by a revolution in his own mind, in his ways of thinking. If these vital inward changes do not take place there is usually little reason for his continuing in graduate work.

All graduate study which properly deserves the name involves research either directly or indirectly. It consists of three parts which are to be developed simultaneously, not successively: (1) One acquires the detailed and specific knowledge needed for research; (2) one develops the spirit of inquiry and consecration to the task of extending the bounds of knowledge—the spirit which characterizes the man of research; (3) one is inducted into the actual labor of discovery, and thus begins to experience what is perhaps the profoundest pleasure of which our nature is capable. Graduate study which lacks any one of these three elements is essentially deficient; it is not taken into account in our discussion below.

But what is research? What gives to it its central place of importance? What are the materials upon which it feeds? Let us first answer the last question.

The man of research should be free to choose his material wheresoever he will. A directing authority would ultimately be fatal to his vitality and destructive of all useful labor. But he must exercise an intelligent choice. Out of the myriads of facts in the universe selection must be made. Some are irrelevant; and these should be discarded. To determine the number of sprigs of grass on the campus or to count the lady-bugs on our planet is not research. These facts—though facts they are—have no permanent character; they do not lead anywhere.

True research consists of any one or more of three kinds of work of equal rank, as follows:

1. Ascertaining new facts of a permanent character or drawing attention to new relations among facts already known. This re-

quires the power to direct attention to things which other people have overlooked, to separate them from the mass of facts in which they are imbedded and to study them first for their own sake and then in relation to other things. The man of research requires the power to see the mosquito on the monument and for the moment to forget the monument for the sake of the mosquito. It is so often the trivial thing which turns out to be important. It is of more concern to us to know the mosquito which holds the power of life and death than to contemplate the battle commemorated by the monument.

2. Deriving the consequences of facts already known. No fact is thoroughly understood until all its consequences are brought into review or the possibility of doing this has been clearly and definitely recognized. Indeed it is only when this has been done that we can be said to have ascertained that the thing is a fact.

3. Developing a body of theoretical doctrine, with or without reference to facts to be accounted for by it. Under this head come such matters as the Mendelian theory of inheritance, the electron theory, the mathematical theory of electricity, projective geometry.

Granting now this definition of research and its fundamental relation to graduate study as outlined above, the question arises as to when the student should begin the actual work of research. Should it be in the first year? Or, should one await a longer period of preparation in order to be better fitted for it? Probably no other subject requires as much preparation for research as mathematics, because in this the whole body of doctrine is closely connected and interdependent. Many extensive parts of it can be learned in essentially only one order. One may compare it to a tree. The trunk corresponds to the fundamental parts of the subject, the branches are the subdivisions, the remoter twigs are boundaries of present knowledge, and it is here that new truth is principally to be developed. Before one is ready for research he must ascend the trunk, so to speak, and climb out along some

vigorous branch to the twigs near its end. All this takes time. And yet, if my short experience is not misleading, this may be tentatively accomplished even in the first year of graduate study. To be sure, such early research is crude; it could hardly be otherwise. Probably one should seldom allow it to see the light of day, so far as publication is concerned. And yet to do such preliminary research is a matter of importance to the student. The power of independent thinking depends first of all on a certain natural aptitude, but it is capable of cultivation. The way to develop this power is to exercise it; and the sooner one begins the better. Too much acquisition and too little discovery undoubtedly benumb the faculty of initiative.

But how is one to get started on research with some promise of successful achievement? Is there a guide who can induct him infallibly into the inner secrets of the creative power? Fortunately or unfortunately, there is no flowered path leading through fields of research, in fact, there is no path at all; every one must blaze out his own trail.

Very few people have sufficient initiative to acquire this ability unaided, or even by the aid of books. The living instructor is usually essential. A certain body of traditional lore is passed on from generation to generation of thinkers and is never reduced to writing. One needs to draw from this source of inspiration. To acquire the power of research one needs to get close to some one who has it, to surprise him in the act of creative thinking and to learn his ways of working. No one is more pleased at this than the thinker himself, for he realizes how hard it is to transmit to others his acquisition, and yet he knows that this is the most important service which he can render. To transmit to others that elusive thing called point of view is at the same time the most important and the most difficult work of the instructor.

I have said that few individuals have sufficient initiative to acquire independently the power of research. On the other hand, I believe that there are many who may develop

into successful workers if they come into intimate relations with a gifted instructor. The extraordinary success of students trained under such a man as Agassiz, for instance, is sufficient proof of this. He kindled a fire of enthusiasm which never burned out.

But why should one wish to acquire this power? The labor involved in its exercise is arduous. The material rewards are not great. The majority of one's contemporaries will not realize the importance of his work. In a little circle only, the inner circle of one's colleagues, will the labor be adequately appreciated. Therefore it is clear that whatever encouragement one has in undertaking such work must be of the higher sort, it must be ideal in its nature. To help you to see the true reasons for doing research is the principal purpose of this discourse.

First of all, what is the meaning of research to the individual who does it? What selfish end may he expect apart from the pleasure of service to his fellows? To do effective research is to know the spirit of mastery, the spirit of mastery where no one else suffers the pang of defeat. It is to develop the sense of superiority of mind over that which is not mind. It is consciously to obey the command to subdue the earth. It is to replenish it with a new creation. It is to make the universe a little fuller and richer by understanding it better.

But more than all this to the individual: he learns what it is to grow. Knowledge obtained otherwise is a sort of accumulation adhering to one outwardly; but when it is attained by independent research it is more like an integral part of one—not merely a possession, but an element of his very being. What I am saying will be made clearer by means of an illustration. A magnet attracts to itself iron filings and holds them indefinitely if they are not forcibly torn away; but however long they are kept in position, they do not become part of the magnet. The knowledge which is gotten by the usual means of acquisition is like these filings; it adheres to one externally. On the other hand, that which is discovered

through research is like the material which a plant takes up into itself in the process of growth; it becomes a part of one's essential being. Thus the work of research furnishes a means of self-development which is to be had in no other way. From this point of view to do such work will be a special privilege to one in proportion as he considers his individual development a matter of importance.

There is also a further advantage. When one has learned what it is to see a thing in the flood of light which research throws upon it, all knowledge begins to take a new appearance. The light of research reaches beyond the field in which it was kindled and illuminates the neighboring territory, and finally one's whole body of exact information. It puts one in a new world even while he is amid his old surroundings.

Let us next inquire, What is the meaning of research to the university? The way in which the reputation of the university, and consequently its power of service, depend on the character and amount of research done by its staff and graduate body is sufficiently objective to be in no danger of escaping your attention; and therefore I shall pass over this matter without further remark. But there is another thing more intimate, more subjective in its nature and more important in its influence, which, by its very closeness to your experience, may fail of appropriate recognition on your part. I refer to the atmosphere, in the academic community, which in large measure is created by your presence and work. This has a pervasive influence of a peculiar kind, and every environment which feels it is vitally affected by it. Every department of the institution is indebted to it for new tone and fresh vigor. A breath of life is infused into the undergraduate work and an inspiration otherwise unknown is felt. An institution in which pure research is regularly done has an atmosphere of its own which provides a training, even for the undergraduate who is not doing research, which can be secured in no other way. Through its students it contributes to the community at large a vital influence of far-reaching power.

It is obvious that a power of this kind may be utilized with different degrees of effectiveness. I believe that it often lies in part dormant, through the failure of graduate students to develop an appropriate *esprit de corps*. The great value to each individual of the spirit which pervades the undergraduate body is well known to all of you. A similar advantage may well accrue from the *esprit de corps* of an organized body of graduate students; and such a club as the present one is effective in contributing to this end. The wide divergence of interests in the various departments makes it harder to find common grounds of association than in the undergraduate work; but the advantages to be obtained are well worth an effort.

Again, let us ask, What is the meaning of research to the larger community of which the university forms a part? What immediate practical ends are attained? What more ideal and far-reaching results are accomplished?

It is one of the paradoxes of human progress that certain practical ends are best served by work which is laid out independently of practical considerations. It is only when one develops truth for the sake of truth itself that one takes sufficient time to forge all the links in the complete chain of theory. If the attainment of a practical end is the purpose in view minor matters which appear irrelevant will be entirely ignored, for the sake of economy of time. But if one is interested primarily in the development of science, no considerations, however unimportant they appear, are left out of account. One's esthetic sense can be properly gratified only by an all-comprehensive investigation of his subject. Consequently the man of research looks at his subject from all points of view and develops a complete theory simply for the sake of his delight in its beauty. When he has finished, it is often found that his discoveries are unexpectedly of great practical importance, sometimes directly and sometimes indirectly. Human progress owes a boundless debt to such agency.

Every science affords examples of the prac-

tical value of research to the community at large; but I shall not take time to enumerate any of these.

The chief value of science does not consist in the concrete advantages upon which we can readily lay our hands. All the beautiful results of an ideal nature which are accomplished for the individual researcher also accrue in a greater or less measure to the community at large. A new sense of mastery and adequate grasp of things pervades the general mind when the people realize that the thought of their generation is being developed in part by the men who go in and out before them. There is a feeling as of access to the inner circle of thought which is vivifying in its influence, when we know that those with whom we are associated are of the company of truth discoverers. There is a new tone to the community, and a fresh impetus to its study of the wider problems. Can any community remain the same when it receives a Newton, a Poincaré, a James, a vital man of research in any field?

This is a partial statement of the significance of research to the contemporary generation. But its influence reaches beyond the investigator's community or the political unit to which he belongs. It overflows into the whole world of thought, and thus contributes with great effectiveness to a modern movement which by many is believed to mark the beginning of a new era in human history. I refer to the widespread and universal feeling of brotherhood in man, a feeling of common sympathies and common interests which know no geographical or political or racial boundaries. The spirit of research, by its complete independence of everything which separates man from man, binds together elements of the most diverse origin into a common brotherhood in which all feel the same thrill of discovery, the same consecration to the task of extending knowledge, the same incentive to labor for human progress. It is the organizations of men of research which have the most effective international congresses; and the spirit which pervades these meetings

is delightful. May we not see in this a forerunner of that day when all men will recognize the extent of their common interests, however diverse the outward forms of their life or their physical surroundings?

Whatever is of present advantage reaches out also to the future; and consequently everything which we have said so far may be applied in partial answer to the question, What is the meaning of research to the future of the human race? But such an answer is indeed partial; there are yet other essential things to add before it is made complete.

If we seek to look into the future we can succeed only by the light which is afforded by the past. Therefore let us examine briefly certain typical instances illustrating the way in which the research of one period has had its full fruition only in succeeding generations. You will pardon me if I draw these principally from the field with which I am best acquainted.

In the great days of ancient Greece her mathematicians were deeply interested in the study of the various curves which may be obtained as the intersections of a circular cone and a plane; and they developed many of the properties which belong to them, especially those of a metric nature. The incentive to this study was the esthetic delight in the body of doctrine itself; no important practical applications of their results were found—none was sought. For many generations this Greek theory of conic sections was transmitted without essential modification and without application to practical matters. Finally, through his acquaintance with this theory, Kepler was led to observe that planetary paths are a special kind of conic section; and his famous three laws of astronomy were discovered and made known. After a further lapse of time, Newton's meditations on Kepler's laws led to his formulation of the theory of gravitation, with the fundamental law of inverse squares as the basis. This in turn furnished the necessary foundation for celestial mechanics, and this magnificent structure was reared by several workers, notable among

them being Laplace. If we follow this chain further we shall find that celestial mechanics became the model for an exact science of any class of natural phenomena; and men sought to fashion the whole of mathematical physics after the same plan. It would be hard to overestimate the influence exerted in this way on modern science with all the practical consequences which it has introduced. It is fair to say that we are now reaping some of the practical benefits of the old Greek theory of conic sections, since this theory furnishes one of the essential tools by means of which our present body of science has actually been developed.

Let us take from Greek mathematics another example which illustrates the way in which the value of research is cumulative. Consider Euclid's geometry. It contains an ideal body of doctrine whose form is evidently determined by the author's delight in logical consistency and coherence. It is even yet a model according to which one fashions a careful logical exposition. As is well known, the ordered sequence of its propositions was the guide of the English philosopher Hobbes in constructing his body of philosophical doctrine.

A more recent and totally different kind of example of the value of research is afforded by Mendel's theory of inheritance. About fifty years ago Mendel was engaged in ascertaining the effect produced in various characters by crossing two varieties of peas; for the explanation of the facts which he gathered he offered a theory of inheritance which has since had a remarkable influence on biological thought. And now it appears as if results of profound importance to human progress will arise from the increased knowledge of heredity which Mendel's laws afford.

Examples of this kind might be multiplied indefinitely. The way in which practical consequences of great value have come unexpectedly from research in the past reminds us indeed that specific prediction is useless. When we notice the marvelous rapidity with which scientific facts are now gathered and

compare this with the experience of the past, when we see the present magnificent consequences from the relatively meager material for work in the older time, we feel like asking, What is to be the future of research? To what grandeur will it attain? What blessing will it not bring to the human race? One does not dare to assign a limit to its possibility. How far short of the present marvels of science would have been the boldest predictions of the fathers of a hundred years ago!

A work which in the past has proved itself of so profound importance deserves adequate support in the present. Whence is such support to be derived? I wish to answer this question by saying that every unit in the world community should contribute to it. The state of Indiana should sustain her proper share of men of research, and for the further reasons which I am about to state.

That community in which research of the best quality and greatest amount is done will profit most by the total research of the world. Of course those communities which contribute nothing will in the end receive great benefit also. It will be later in coming to them and it will not manifest that vitality which characterizes it in more favored places; but it will come. A sense of fair play and a wish to profit to the fullest extent require, however, that each state shall properly support research in its own borders. Otherwise it becomes a sort of leech drawing its sustenance in part at the expense of the world at large. And no patriotic citizen can ever consent that his state shall be a pensioner on the bounty of others; it must do its part in the work of general progress.

#### THE TENTH INTERNATIONAL GEOGRAPHICAL CONGRESS

UNDER the sunniest of Italian skies the tenth International Geographical Congress was convened on the morning of the twenty-seventh of March in the historic Aula of the palace of the Campidoglio in Rome. His Majesty,

Victor Emmanuel, honored the occasion with his presence, and brief speeches of welcome were made by the mayor of the city, by Marquis Capelli, the president of the congress, and by the Italian Minister of Public Instruction, to which welcome Professor Otto Nordenskiöld, of Sweden, responded on behalf of the delegates present.

Seldom has so attractive a program of papers been prepared as that which was mailed to geographers throughout the world; but, alas, two successive postponements together amounting to nearly two years, might well be thought sufficient to dampen the enthusiasm alike of committee and prospective guests. It is, therefore, a pleasure to be able to state that in the face of these discouraging conditions the congress was a distinct success; though probably less than it would have been had not the committee decided to adhere strictly to the original program of papers by absentees and refuse all papers offered later than October, 1912.

A partial list of well-known geographers who were in attendance includes: Bruce, Brückner, Chaix, Chisholm, v. Cholnoky, Close, Cvijic, Déchy, Gallois, Hamberg, Heland, Kövesligethy, Lescointes, Loczy, de Margerie, Nordenskiöld, Oberhummer, Peary, Passarge, Penck, Pumpelly, de Quervain, Schott, Schokalsky, Sapper, Stefanssen, Supan, Teleky, Vidal de la Blanche, Wagner and Woeikof.

Geographers of all nations vied with each other in showing honor to Admiral Peary, the discoverer of the North Pole, who represented at the congress both the Association of American Geographers and the Peary Arctic Club. The only other Americans in attendance were Vilhjálmur Stefanssen, the explorer, who represented the American Museum of Natural History, Professor Raphael Pumpelly, Mr. H. L. Bridgeman, representing the American Geographical Society and the Geographical Society of Philadelphia, and the undersigned, as delegate of the American Philosophical Society and the University of Michigan.

As might have been expected, the congress

was less notable for important papers presented than by reason of programs decided upon for international cooperation. Dr. de Quervain presented, however, a preliminary report upon his crossing of Greenland in 1912, and exhibited for the first time his final map of the route and his section across the continent. Professor Emile Chaix, on behalf of the executive committee of the commission on a collection of views to illustrate the terrestrial relief, made a most attractive presentation of the work already accomplished. Mr. Stefanssen described the geographical features of the country traversed on his recent expedition to Arctic America, and outlined briefly his plans for an expedition to Coronation Gulf soon to be undertaken by him for the Canadian government. Captain W. S. Bruce, after giving an account of his Antarctic expedition in the *Scotia*, outlined a projected expedition which will have for its object the direct crossing of the Antarctic continent from the Weddell Sea to McMurdo Sound by way of the South Pole and the inland ice plateau to the west of the mountain ranges in Victoria Land. Professor Kövesligethy, of Budapest, described his method for the prevision of earthquakes based upon the analytical expression of the hysteresis of the earth's outer shell, with data supplied from the velocity of wave propagation. Professor Gaetano Platania described the latest eruption of Mt. Etna with quite remarkable lantern slides from photographs taken by Mr. Frank A. Perret, the American vulcanologist.

At the request of the International Commission for the preparation of the "millionth" map of the world, it was decided to hold another official conference, which will be convened in Paris before the close of the present year, to which all civilized nations will be invited to send delegates. For the present the office of the Ordnance Survey in London is to remain the official center of the enterprise, to which therefore all correspondence should be addressed. The congress approved a proposition to prepare a "Universal Geography" to accompany the millionth map, but

no plans were formulated for so pretentious an undertaking. Based upon this world map, it is proposed also to prepare an international aeronautical map of the world on scale of 1:200,000, and an official conference to determine the details is to be convened.

The delegates voted in approval of the proposition that the most important problems to be settled in connection with the international exploration of the north Atlantic Ocean relate to the size, the regional extent and the nature of periodic variations of water layers to the depth of 1,000 meters, and it was recommended to continue systematic observations upon ocean currents and upon the temperature and salinity near the surface of the sea.

The proposition of the Danish Geographical Society was approved to invite the geographical societies of Rome, Madrid, Lisbon, Geneva, London, Berlin, Vienna, New York, Paris, St. Petersburg, Copenhagen, Brussels, Amsterdam, Christiania, Stockholm and Budapest to meet in Denmark in 1914 for the purpose of organizing a World Union of Geographical Societies. A large committee was appointed with one or more members from each country possessing ancient maps of its domain, for the *refection* of these maps, these gentlemen being charged with the preparation of a catalogue to be printed in a geographical journal before the opening of the next congress. Dr. E. L. Stevenson, of the Hispano-American Society of New York, was made the representative for Spain.

Much enthusiasm was shown in approving a proposition to organize in each country during the summer vacation periods of the higher institutions of learning, international courses of instruction in geography, in which foreign savants would be invited to take part. The plan contemplates also the founding of an International Geographical Institute, the seat of which is left for later determination, this institute to direct and coordinate the studies and all geographical initiatives which have an international character.

The difficult questions concerned with the confusing duplicate place names on international frontiers (such, for example, as the

Alps and Pyrenees) it was voted to refer to a commission with a view to securing the general use in each case of a single term, or, when this seems impracticable, terms which are in correspondence. After a warm discussion the proposal to add Spanish to the four official languages of the congress was definitely and decisively rejected. The eleventh international congress it was decided to hold in St. Petersburg in 1916, with a rather general understanding that the next succeeding congress would be convened in Vienna.

The social events included a reception at the palace of the Campidoglio and a complimentary dinner tendered to the delegates by the committee of organization. Delightful local excursions were made to Tivoli, Ostia, Terni and the Alban Hills; and after adjournment there were longer journeys to the Po Valley and Préalpes on the one hand, and upon the other to Naples (Mt. Vesuvius and the *Campi Phlegreäi*), Sicily (ascent of Mt. Etna) and Tripoli.

The weather throughout the meeting was perfect and the campagna at its best in its spring garlands of flowers; but it may be questioned whether Rome is not, even without these allurements, too interesting in itself to be an ideal seat for international congresses.

WM. HERBERT HOBBS

April 15, 1913

#### SCIENTIFIC NOTES AND NEWS

PROFESSOR J. M. ALDRICH, the circumstances of whose enforced retirement from the professorship of zoology and entomology at the University of Idaho, are described by Professor Vernon L. Kellogg in this issue of SCIENCE, has accepted a position in the Bureau of Entomology, U. S. Department of Agriculture.

THE American Geographical Society has conferred its Charles P. Daly gold medal upon Dr. Alfred H. Brooks for his geological and geographical work in Alaska.

THE Georg Neumayer gold medal was bestowed upon Dr. L. A. Bauer, director of the Department of Terrestrial Magnetism of the

Carnegie Institution of Washington, on May 3, in connection with the celebration of the eighty-fifth anniversary of the Berlin Gesellschaft für Erdkunde. The medal is awarded to Dr. Bauer for his researches in terrestrial magnetism. Professor Neumayer, who founded the medal, will be recalled as the most eminent student, during his lifetime, of the earth's magnetic phenomena. The medal has not been awarded since 1906.

DR. GEORGE H. BARTON, director of the Teachers School of Science, Boston, was given a dinner and a presentation on May 9. Among those who made addresses were President MacLaurin, Professor Sedgwick and Professor Burton, of the Massachusetts Institute of Technology; Professor Woodworth and Professor Ropes, of Harvard University; Professor Fisher, of Wellesley College, and Professor Lane, of Tufts College.

DR. ROSSITER W. RAYMOND, of Brooklyn, was elected an honorary member of Alpha Chapter of Tau Beta Pi at a joint meeting of Tau Beta Pi and Phi Beta Kappa, at Lehigh University last week.

SIR DAVID GILL, formerly astronomer at the Cape of Good Hope, has received the insignia of commander of the Legion of Honor, which has been conferred on him by the president of the French Republic.

THE council of the Institution of Civil Engineers has made the following awards for papers read during the session 1912-13: A Telford gold medal to Mr. Murdoch Macdonald, C.M.G. (Cairo); a George Stephenson gold medal to Mr. G. D. Snyder (New York); a Watt gold medal to Mr. H. A. Humphrey (London); Telford premiums to Messrs. C. W. Methven (Durban), B. Hall Blyth, Jr. (Edinburgh), C. J. Crofts (Durban), Frank Grove (Canton), B. T. B. Boothby (Hankow), and Francis Carnegie (Enfield Lock), and the Manby premium to Capt. C. E. P. Sankey, R.E. (London).

PRESIDENT WILSON received on May 6 a committee of the American Medical Association, which urged a general conference to discuss plans for a federal department of public

health and matters pertaining to the conservation of human life and efficiency. Professor Irving Fisher, of Yale; Dr. John B. Murphy, of Chicago; Dr. G. H. Simmons, of Chicago; Dr. L. K. Frankle, and Dr. Abram Jacobi, of New York; Dr. Harvey M. Wiley, Senator Owen, and Representatives Foster, of Illinois, and Curley, of Massachusetts, were present.

DR. PAUL MARCHAL, chief of the Entomological Station of Paris, professor in the Agronomical Institute of France, and a member of the French Academy of Sciences, landed in New York on the fourth of the present month. He comes to America for the purpose of studying the organization of the Bureau of Entomology of the Department of Agriculture at Washington and other organizations working in applied entomology. He will remain in the United States for two or three months. Dr. Marchal is especially well known to general students of biology and morphology on account of his remarkable researches in polyembryony. In the course of his stay he will visit most parts of the United States.

DR. PEER GEIJER, the Swedish geologist, has joined the University of Wisconsin expedition to the Lake Superior mine regions. The party consists of advanced students in the engineering college and professors. The inspection tour is made every two years. Besides Dr. Geijer, J. J. O'Neill, of the Canadian Geological Survey, and G. W. Crane, of the Missouri State Geological Survey, are of the party.

PROFESSOR W. J. BAUMGARTNER, of Lawrence, Kansas, will conduct his fourth party of biologists to the Puget Sound Marine Station at Friday Harbor, Wash., this summer. A chartered car will leave St. Paul on the morning of June 14, and will go over the beautiful Canadian Pacific route, stopping to visit glaciers, etc. Six weeks will be spent on the coast studying the exceedingly rich fauna and flora under very favorable conditions.

PROFESSOR HENRY H. NORRIS, head of the department of electrical engineering at Cornell University, has resigned to join the editorial boards of *The Electric Railway Journal* and *The Electric World*, of which he has been an associate managing editor for some years.

AMONG those who spoke at the dedication of the engineering buildings on May 8 and 9, at the University of Illinois, were Mr. Samuel Insull, president of the Commonwealth Edison Company; M. J. G. Panghorn, special representative of the Baltimore and Ohio Railroad; Mr. John Hays Hammond, mining engineer, American Institute of Mining Engineers; Mr. W. L. Park, vice-president Illinois Central Railroad; Mr. Isham Randolph, consulting engineer, Chicago, and Governor Edward F. Dunne.

MRS. CHRISTINE LADD FRANKLIN, of New York City, gave last week at Columbia University and is giving this week at Harvard University three lectures on "Color Vision."

ON April 7, Dr. Haven Metcalf, of the Bureau of Plant Industry, lectured at the University of Wisconsin on "The Work of the Government in Forest Pathology."

THE Linacre lecture of Cambridge University was delivered by Dr. Norman Moore on May 6 in the lecture room of anatomy and physiology, New Museums. The title of the lecture was "The Physician in English History."

SIR J. ALFRED EWING gave a lecture on the structure of metals before the Durham Philosophical Society on May 2.

A COMMITTEE has been formed, with the king of Italy as president, to establish suitable memorials of the late Professor Giovanni Schiaparelli, the distinguished astronomer.

THE teachers of the Normal School at Avignon, of which M. J. H. Fabre, the entomologist, was a pupil, are taking steps to erect a monument in his honor. The council of Vaucluse has voted 1,500 francs to the fund.

MR. SHINOBU HIROTA, who recently returned to Japan after assisting Professor Milne for eighteen years in his work in seismology, died on April 24.

THE British government intends, as we learn from *Nature*, to ask parliament to sanction a special vote sufficient to provide as follows: For Lady Scott (in addition to the Admiralty pension of £200 per annum for herself and £25 per annum for her son, until he

reaches the age of eighteen) an annuity of £100. For Mrs. Scott, the mother, and Mrs. Campbell and Miss Grace Scott, the sisters, of Captain Scott, a joint annuity of £300. For Mrs. Wilson, the widow, and Miss Mary Souper, the sister-in-law, of Dr. E. A. Wilson, a joint annuity of £300. For Mrs. Evans, the widow of Petty Officer E. Evans (in addition to the pension and allowances awarded to her by the Admiralty, amounting to 13s. 6d. a week), a further annuity of 12s. 6d. a week for herself and 3s. a week in respect of each of her children up to the age of eighteen. The government of India, in the service of which Lieutenant Bowers was before joining the expedition, has offered to provide pensions, amounting in all to £100 per annum, for his mother and sisters. Captain Oates, the fifth member of Captain Scott's southern party, was unmarried; and as no mention is made of any relatives, it may be assumed that he was possessed of ample means. In addition to the provision referred to, the total amount subscribed by the public as a memorial for the dead explorers and kindred purposes is £55,760.

THE surgeon general of the army announces that preliminary examinations for appointment of first lieutenants in the army medical corps will be held on July 14, 1913, at points to be hereafter designated. Full information concerning these examinations can be procured upon application to the "Surgeon General, U. S. Army, Washington, D. C." The essential requirements to secure an invitation are that the applicant shall be a citizen of the United States, shall be between 22 and 30 years of age, a graduate of a medical school legally authorized to confer the degree of doctor of medicine, shall be of good moral character and habits, and shall have had at least one year's hospital training as an interne, after graduation. The examinations will be held simultaneously throughout the country at points where boards can be convened. Due consideration will be given to localities from which applications are received, in order to lessen the traveling expenses of applicants as much as possible. In order to perfect all necessary arrangements for the examination,

applications must be completed and in possession of the adjutant general at least three weeks before the date of examination. Early attention is therefore enjoined upon all intending applicants. There are at present forty vacancies in the medical corps of the army.

THE International Association of Medical Psychology and Psychotherapy will hold its annual meeting at Vienna on September 18 and 19, immediately before the opening of the Congress of German Men of Science and Physicians.

MINING students of the University of Illinois will hold a mining exhibit in connection with the dedication of the Mining Laboratory on May 8, 9 and 10. This will consist of a display and demonstration of the heavy mining machinery and apparatus of the new building.

THROUGH the cooperation of the Bermuda Natural History Society and Harvard University, the Bermuda Biological Station for Research will be open this summer as usual for about six weeks, from the middle of June till August. Botanists or zoologists wishing to avail themselves of this opportunity should communicate with Dr. E. L. Mark, 109 Irving St., Cambridge, Mass.

DURING the months of July and August the facilities of the Seed Laboratory of the Bureau of Plant Industry, U. S. Department of Agriculture, Washington, D. C., will be available as far as space permits to any one who wishes to consult the seed collection and become familiar with the practical methods of seed testing for mechanical purity and germination. For further information address Mr. E. Brown, botanist in charge.

SECRETARY DANIELS has withdrawn the offer of warships for the use of college students because of the new plans for the Atlantic fleet. Sending the fleet through the Mediterranean will make it necessary to use some of the ships, now in reserve, for various details. Consequently there will be none left that will be available for the use of college men.

At the recent annual meeting of the Naples Table Association for Promoting Laboratory Research by Women, the use of the table supported by the association at the Zoological Station at Naples was granted for the coming year to Dr. Rhoda Erdmann, of Berlin, Germany, and Dr. Caroline Thompson, professor of botany at Wellesley College. The Ellen Richards research prize of \$1,000 for the best thesis written by a woman on a scientific subject embodying new observations and new conclusions based on independent laboratory research in biological, chemical or physical science, was awarded to Miss Ida Smedley, London, England, D.Sc., London University, who has been working for the past four years in the biochemical laboratory of the Lister Institute of Preventive Medicine. The subject of the winning thesis was: "An Investigation into the Methods of Formation of Fatty Acids from Carbohydrates in the Organism." Ten theses were submitted in competition. The examiners for the award of this prize were: Dr. W. H. Howell, Johns Hopkins Medical School; Dr. Theodore Richards, of Harvard University, and Dr. Henry Crew, of Northwestern University. The following officers were elected:

*President*, 1913-14—Miss Ellen F. Pendleton, president of Wellesley College.

*Treasurer*, 1913-14—Mrs. Elizabeth L. Clarke, a trustee of Smith College.

*Secretary*, 1913-16—Mrs. Ada Wing Mead, of Providence.

THE Utah Eugenics Society met on April 3, for permanent organization, having existed under temporary organization since May 20, 1912. The committee on permanent organization reported constitution, by-laws, and recommendations to the meeting and nominations for officers. After a short program, consisting of talks on various phases of eugenics by Mr. Mathohniah Thomas, Professor E. C. Gibbs, of Salt Lake High School, Mrs. Martha C. Jennings, matron of women, Salt Lake City High School, Dr. E. D. Ball, of the Agricultural College, the following officers were elected:

*President*—Mathohniah Thomas, Salt Lake City.

*First Vice-president*—J. C. Wheelon, Garland.

*Second Vice-president*—Dr. Fred Taylor, Provo.

*Secretary and Treasurer*—Dr. E. G. Titus, Logan.

*Members of the Council*—Mrs. Martha C. Jennings; Professor Jacob Bolin, Salt Lake City; Dr. E. G. Gowans, Ogden.

It is stated in foreign journals that the scheme for a canal to open through communication between the Black Sea and Baltic by linking the systems of the Dneiper and Duna seems now in a way to be realized. It is said that the necessary capital of 450 million roubles will be supplied by a foreign country, and that official permission for the commencement of operations will at once be given. Great hopes are entertained of the commercial development likely to ensue from the making of the canal, which will open up an important route for the export not only of Russian corn, but of timber, ores, petroleum, etc., as well as for the import of coal. It is pointed out that the railway freight across Russia is at present some 20 kopeks per pood, to which some 4 or 5 kopeks must be added as sea-freight to Hamburg or England; that the southern sea-route from Odessa involves a freight of 7 or 8 kopeks, with an additional sum of anything up to 6 kopeks for railway transport to Odessa; whereas the freight from Kherson to Riga is reckoned at only 3 to 5 kopeks per pood by the canal now to be constructed. Another important scheme lately put forward is for a canal to open communication between Central Russia and Siberia by linking the systems of the Volga and Obi-Irtish. The proposed route would make use of the Chusov and a tributary, on the west of the water-parting; and the Reshotka, Isset and Tobol on the east, thus entering the Irtish close to Tobolsk. The length is 1,100 miles, and the waterway is designed to take vessels of 5½ feet draught and a length of 350 feet. The general question of the development of Siberian waterways will shortly, it is said, be investigated on the spot by a commission of engineers.

ACCORDING to *The British Medical Journal* an institute for Medical Research in South Africa is being established at Johannes-

burg on the southern portion of the ground lying to the west of the general hospital and to the south of the fort. There has hitherto been no medical research institute in South Africa. A veterinary institute was erected and equipped by the government some time ago at Dasbort, eight miles from Pretoria, but though the need for a medical research institute has been pressed by members of the medical profession, financial objections have prevented any forward movement. Recently, however, the government and the leaders of the mining industry collaborated, with the result that generosity on both sides has provided not alone for the building and equipment, but also its maintenance. The new institute at Johannesburg is to serve the whole of South Africa and will be called the South African Institute for Medical Research. The industrial diseases of the Transvaal will probably first call for consideration, owing to the mortality which they have occasioned, but the work will not be limited to these diseases, and it is hoped to attract skilled workers from Europe to aid the director in his researches; it is probable that research fellowships will be available for suitably qualified medical men desirous to carry out special lines of research. The proximity of the institute to the general hospital, which is the largest in South Africa, and the fact that it will be equipped with four wards, with twenty or thirty beds for the treatment of patients, will serve to associate the institute with medical work in Johannesburg. When the institute is in full working order it is probable that courses in bacteriology and pathology will be arranged for medical students. Two appointments have already been made to the staff. The director of the institute is Dr. Watkins-Pitchford, and the statistician, Dr. G. D. Maynard. Dr. Watkins-Pitchford was formerly house-physician to St. Thomas's Hospital, London; he studied plague in India, enteric fever in South Africa during the war, smallpox in London. For the last ten years he has been government pathologist and analyst for Natal, and last year was transferred by the union government to

Johannesburg. Dr. Maynard was formerly M.O.H. for the suburbs of Pretoria, and subsequently assistant medical officer to the Witwatersrand Association. It is expected that the building will be completed in about a year.

THE British secretary of state for the colonies has, as we learn from *Nature*, appointed a commission to study the nature and the relative frequency of the fevers occurring amongst the Europeans, natives and others in West Africa, especially with regard to yellow fever and its minor manifestations.

M. JULES DE PAYER, as we learn from foreign exchanges, has furnished particulars of his projected Arctic expedition, which is intended to leave France in the summer. With the support of the government and various societies, he will follow his father, the distinguished explorer, in making for Franz Josef Land. One of his objects is to locate the margin of the polar basin to the northeast of that archipelago, an investigation which, if successfully carried out, will provide data for an estimate of the relative areas of the basin and the continental shelf in that quarter of the Arctic region. A scientific staff will accompany M. de Payer, with equipment for the prosecution of research in all the various departments which have become associated with polar work; among them the investigation of the upper atmosphere by means of kites is specially indicated. The party will be provided for a sojourn of one year or longer in the north, its ship returning in the meantime. It is to be provided with two aeroplanes, the utility of which as instruments in polar research will be observed with interest: a visit to the pole itself is mentioned as a possibility, but does not appear as a prime object of the expedition. Wireless telegraphy will be installed at the headquarters.

THE Washington Academy of Sciences has held a field meeting including the region of Cape Henry and Yorktown, which left Washington by a special steamer on April 25 and returned on April 27.

THE regular monthly meeting of the State Microscopical Society of Illinois was held on April 10, 1913, at the rooms of the Chicago Press Club. The subject for the evening was "Bacteria, with Practical Demonstration in preparing Slides and Cultures," by Margaret Grant, A.M., M.D. At this meeting final reports of the recent soiree by the society and the Academy of Sciences, held in the academy building, Lincoln Park, were submitted, showing that there were twelve hundred persons in attendance. Sixty-one microscopes were in charge of forty-eight exhibitors.

#### UNIVERSITY AND EDUCATIONAL NEWS

THE board of regents of the University of Nebraska, at its annual meeting, voted a general increase in salaries of deans and professors, distributing thus the \$35,000 additional maintenance voted by the last legislature.

THE faculty of the Ohio State University has adopted an arts-agricultural course, five years in length. The first three years, students will be registered in the Arts College; the last two years, in the Agricultural College. At the end of the fourth year, the degree of bachelor of arts will be given, and at the end of the fifth year, the bachelor of science in agriculture.

THE Phi Beta Kappa elections for the year at the University of Wisconsin indicate that women students excel men in scholarship, as twenty-two of the thirty-six elections were women.

PROFESSOR OSKAR BOLZA, of the University of Freiburg, is to offer courses this summer at the University of Chicago on "Linear Integral Equations" and "Functions of a Complex Variable." Other graduate courses in mathematics are announced on "Fourier Series," "Linear Continuum and Point-set Theory" (Moore); "Projective Geometry" (Bliss), and "Modern Theory of Analytic Differential Equations" (Moulton). Dr. F. A. Lindemann, of the University of Berlin, is to lecture throughout the summer quarter at the University of Chicago on "Kinetic The-

ories." Other graduate lecture courses in physics are announced on "Relativity" (Lunn), "Wireless Waves" (Kinsley), "Radiation Theories" (Millikan).

DR. FRANKLIN D. BARKER has completed ten years of service in the University of Nebraska and has been made a full professor, having charge of the work in medical zoology and parasitology in the department of zoology.

DR. IRA D. CARDIFF, professor of plant physiology and bacteriology in Washington State College, has been appointed head of the department of botany. Professor John G. Hall, of the South Carolina Agricultural College, has been appointed professor of plant pathology in the same institution.

To the professorship of bacteriology in Columbia University made vacant by the death of Dr. Philip Hanson Hiss, Dr. Hans Zinsser, professor of bacteriology in Leland Stanford University, has been appointed.

#### DISCUSSION AND CORRESPONDENCE

##### UNIVERSITY LIFE IN IDAHO

TO THE EDITOR OF SCIENCE: Professor J. M. Aldrich, professor of zoology and entomology in the University of Idaho (Moscow), has just been summarily dismissed without trial or official warning after twenty years of faithful and successful service. The conspicuous incidents connected with this matter are few, simple and suggestive. They are the following:

In 1900 James A. McLean, a young Canadian, came to the University as president and director of the agricultural experiment station. He was a doctor of philosophy from Columbia in economics. He found the duties of director of an agricultural experiment station bewildering and uncongenial.

In 1904 Professor Aldrich with five other members of the faculty protested to the board of regents that the president was incompetent for his place. Strangely neither the president nor the protesting professors were dismissed but a compromise was effected which endured for eight years. It may be inferred from later occurrences that despite the long and healing

lapse of time, the criticized president did not forget nor forgive his critics.

In 1912 President McLean left Idaho to become the president of the University of Manitoba. Before he left he made out, and gave to the board of regents, a list of professors who ought to be dismissed.

Near the end of 1912, Idaho did away with all separate boards for its various educational institutions and put its whole system in charge of a single new board. The law enacting this provided that the old boards shall hold their last meetings in the following spring.

In April, 1913, President McLean, of the University of Manitoba, crossed an international boundary and the boundary of decency and in secret session with the acting president of the University of Idaho made up a list of seven undesirable professors which list was presented to the dying board of regents and promptly acted on. All were dismissed. At the end of the meeting the board died, and its victims received their malodorous notices of dismissal two days after the board had been defunct. Thus Professor Aldrich and six colleagues have enjoyed the peculiar experience of being removed from their positions on the recommendation of a citizen of Manitoba by an official board which passed out of existence before the victims knew what had happened to them.

An appeal to Governor Haines of Idaho has resulted in an official statement that the regents acted entirely within their authority.

No comment seems necessary on these interesting incidents. Professor Aldrich, who is an unusually competent entomologist, and a peculiarly prepossessing and attractive man, will of course have no difficulty in finding work elsewhere. Will Idaho have as little difficulty in getting as good a man to fill his place?

VERNON L. KELLOGG

STANFORD UNIVERSITY, CALIFORNIA

EDUCATIONAL STANDARDS AT AN AGRICULTURAL  
COLLEGE

PERFECT freedom in the expression of ideas and opinions is born of one of two conditions, either full information, or lack of informa-

tion. Any other condition suggests the advisability of caution. Dr. Pritchett in his letter to the Iowa Board of Education speaks with a freedom and confidence suggesting the most intimate acquaintance possible with the ideals, the strength and the attainments of colleges of agriculture. The prescription which he gives appears within itself to follow the most searching and conclusive diagnosis.

Dr. Pritchett's diagnosis consists of two main parts: first, agricultural education, at least for Iowa, should be of a trade school standard and type; and second, agricultural education must be isolated from other lines, particularly from engineering.

Regarding the first of these specifications Dr. Pritchett says:

The school of agriculture ought to teach pre-eminently the trade of farming, even though it does research in its experimental station, and conducts certain classes of high order, its primary function ought to be not the training of agricultural teachers, but the training of farmers, and the cultivation of the means by which the scientific knowledge in a practical form can be put into the hands of farmers. The great part of the work is not on a professional plane. Students of agriculture ought not to be required to comply with the same academic standards as those who expect to enter the profession of engineering. . . . In my judgment the interests of agriculture will be subserved by making the agricultural college a straight-out school of agriculture, with entrance requirements suited to the needs of those who wish to become practical farmers. I should not make these academic requirements for admission higher than the equipment afforded by the elementary schools.

This at least has the merit of being explicit. Dr. Pritchett would take the boy at the same stage of development required for entrance into the freshman year of the high school, and after getting him into this so-called college would teach him how to farm. The objections to this academic program are many, but possibly an illustration may serve the purpose. A man concerned in educational matters in Tennessee had been converted to the agricultural point of view. He made no such mistake as to go to the people with messages of

chemistry, botany or zoology, but on the contrary advocated eminently practical measures. At a meeting up in the hill country he made an address in which he labored long and arduously to prove to the audience that every boy, and every girl, should know how to milk a cow, and to this end should attend an agricultural college. After wearing himself and the audience pretty well out he threw the meeting open for remarks and discussion. After a painful silence, a gaunt old man with hay-colored whiskers, the principal of a theological seminary, arose. "Stranger," said he, "I agree with you that every boy, black or white, should know how to milk a cow. I even agree that every girl should include this art along with her other accomplishments. However, I want to make this suggestion: Wouldn't it be a good thing for a college to teach its students something that a calf couldn't beat 'em at?"

If the farmers send their sons to the agricultural college in order that they may learn how to farm there are going to be a lot of disappointed farmers. At Wheaton, Illinois, plowing matches are held each fall and men who never saw a college do plowing so nearly perfectly that only those experienced in the accomplishment are able to act as judges. This skill could be learned at college, no doubt, but why run a college for teaching an art which can be learned readily in connection with farming operations? The college could no doubt develop great proficiency in the art of husking corn, but it is doubtful whether it could out-do boys who never so much as finished the country school. There are hundreds of men in Iowa who can feed cattle so successfully that few colleges would care to compete with them in the results to be obtained as judged in dollars.

What the farmer should, and does, demand of the college is a solution of the problems which are too intricate for him to solve for himself. The farmer can put fat onto steers about as rapidly as can a college professor, but he can not analyze feeds. Neither can the farmer analyze his soils or identify the pests that infect his crops. Should the college

undertake to teach these things along with the practise of farming to a lad just out of the eighth grade? Manifestly not, and for the reason that to him that hath shall be given. Few of the well-prepared boys who enter college make good scientists. Almost none of those entering Dr. Pritchett's ideal school would be able to comprehend scientific problems at all. They would go back to the farms because unprepared for any of the more advanced lines of agricultural work.

Dr. Pritchett believes that the Iowa State College has turned out more lawyers than farmers. It is too bad to break down a system of beliefs by ruthlessly intruding the facts, but the information at hand shows that about two fifths of the recent graduates of the agricultural courses are engaged in actual farming, while only 5 to 7 per cent. are in non-agricultural work. But few of the graduates have become lawyers. Until the demand for teachers and experimentalists is met it is hard to comprehend where they are to be trained if not at agricultural colleges. It is also difficult to see how these men could be more useful to the state by working a farm than by teaching the sciences pertaining to farming, editing farm papers, or testing hypotheses concerning the application of science to agriculture. This answer must be either that all scientific research is now complete, or else that scientific research is not worth while, since, forsooth, the agricultural college should make its main work the teaching of the art of farming.

The second thing needful in realizing Dr. Pritchett's ideal in agricultural school effort is isolation. This needs no discussion, since the grade of education he has in mind certainly could not flourish in a college, alongside of, and on a par with, real college work. However, the world is big and there is a place for the grade of instruction which the doctor has in mind. In fact it is being offered in the numerous short courses at the college and over the state. There will be more such short courses in the future, but the college will hardly go out of business in order to make room for them. It is not improbable that county agricultural high schools, or even town-

ship schools may, in a way which the college could not, meet the needs which Dr. Pritchett has in mind. Something of the sort has been begun. In Europe this kind of instruction is common, but the agricultural colleges are not sacrificed in order that it may be done. On the contrary, they furnish the teachers and a large part of the subject matter for the courses given in the lower grade schools. A paragraph from Dean Bailey, of Cornell, often called a prophet in agriculture, will not be amiss:

An internal danger is the giving of instruction in colleges of agriculture that is not founded on good preparation of the student or is not organized on a sound educational basis. Winter-course and special students may be admitted, and extension work must be done; but the first responsibility of a college of agriculture is to give a good educational course; it deals with education rather than with agriculture, and its success in the end will depend on the reputation it makes with school men.

B. H. HIBBARD

#### A CALL FOR AMPLE AND TRUSTWORTHY VITAL STATISTICS

THE appeal of Dr. J. Madison Taylor, published in *SCIENCE*, October 11, 1912, for a more general and critical body of human statistics is one which should elicit a ready response upon the part of scientific men generally. No one who has had occasion to investigate a problem involving data of human history but can confirm the deficiencies to which Dr. Taylor refers. Something over a year ago the present writer began an inquiry relating to educational betterment which led to a search of various documents such as yearbooks, census reports, reports of the Bureau of Education, etc., and it soon became apparent that these sources were noteworthy for what they did not contain. In other words, they were woefully lacking in just that class of data which were vital to the inquiry in hand. An inquiry as to the existence of personal and family records soon revealed the fact that here, even more than in the other sources, except in rare instances, it was almost impossible to discover data of any adequate or reliable character.

The importance of such data in their rela-

tion to various problems of human interest is too well known to call for argument. However, it may not be amiss to cite a few incidental phases of such interest, and among them the following are especially important. Maudsley long ago ("Pathology of Mind"), emphasized its importance in relation to questions of insanity.

When we are told that a man has become deranged from anxiety or grief, we have learned very little if we rest content with that. How does it happen that another man, subject to exactly similar causes of grief, does not go mad? It is certain that the entire causes can not be the same where the effects are so different; and what we want to have laid bare is the conspiracy of conditions, internal and external, by which a mental shock, inoperative in one case, has had such serious consequences in another. A complete biographical account of the individual, not neglecting the consideration of his hereditary antecedents, would alone suffice to set forth distinctly the causation of his insanity.

It is hardly necessary to say that what is stated in this case has become greatly more certain in the light of manifold facts of current knowledge.

But important as is such knowledge in its bearing upon insanity as a malady to be cared for or treated, it is even more important in its possible relations to social and economic problems. It is no part of the purpose of this brief paper to deal with these phases of the subject. The problem which has concerned the writer is that of eugenics in relation to educational betterment. With many who have been concerned in the present status and tendencies in educational progress he has had a growing conviction that conditions are deplorably bad in many respects, and in some matters the situation is grave to a degree not generally realized. It is not the ranting criticism of hasty reformers and radicals of quixotic type which is the occasion of concern. But those who know best the situation, those who are upon the inside, the friends of the best in educational tradition and inheritance, have been among the critics, and have not hesitated to cry aloud and spare not. Then, too, we have had opportunity to "see

ourselves as others see us." Our system of education has been designated as a "*Proliferating Mediocrity*." It is thrown into our teeth that the present generation has added little or naught to literary, or philosophic, or scientific greatness; that we take none of the Nobel prizes for scholarly achievement; that American schools are glorified chiefly as a *theoretical system*. To such arraignment we may, or may not plead guilty, according to our points of view. This is not the place to discuss the pros or cons. Conditions have provoked the challenge and criticism. It is serious enough to give us pause, and to awaken inquiry and analysis. Assuming there are possible grounds for criticism, that our so-called system is not perfect, that a tendency to mediocre results exists, what can be done in the matter? And further, what has all this to do with vital statistics?

Considering first the last feature, let it be noted that had there been gathered during the century past a body of school statistics of a critical and informing character we should be in possession of just the data which would enable us to answer some of these questions in a more thorough and convincing manner than is possible without them. It is very well to glorify the values of education by pointing to distinguished jurists, statesmen, educators and others, as products of Harvard or Yale or Oxford, etc., but it may still be open to query whether *all this is so!* The cynic will retort "They were great in spite of this, that or the other college!" And who has convincing evidence for or against?

But this is not the only, or chief, call for statistics. There has long been current, as a sort of creedal tenet, applicable to all sorts of social or civil or religious or educational conditions, the adage *all men are created free and equal!* But deductions of science and sociology have later been declaring the very opposite, that men are created under bondage and to inequality through laws of heredity and variable environment. So far as education is concerned it may be assumed as beyond reasonable debate that the armies of idiocy, imbecility, feeble-mindedness, to mention no

others, prove the latter conclusion all too convincingly.

But among the educable none who has had practical experience with the problem is likely to espouse the older tenet. Limitations and inequalities are obvious conditions, not for the schools alone, but for every vocation or avocation of human life. Now, in theory, all this has been quietly ignored. We have framed our curricula, whether of kindergarten, school or college, on the older assumption. There have been *radicals* at work on the curricula of schools for delinquents and imbeciles, and the latter view of human nature has been unhesitatingly accepted as settled. But not so in the schools for normal and subnormal children. Here we still adhere to the older assumption; and while the dunce-cap or the rod may have passed as an index of our inherent faith in our creed, still there are other evidences of the integrity of our creedal loyalty! And how has it worked out in practice? The answer, at least in part, is simple and obvious. Scholarly standards have been made to suit *averages*. While a large proportion are capable of successfully achieving the general average, a considerable proportion could just as easily attain the highest rank of efficiency. But first consideration has been given to the mediocre or average class. The pupil of fine ability, of potential genius, has been allowed to drift, to loaf after the easy task of the average has been met in an indifferent way! And what of the backward or low grade pupil? Here too has there been the same ill-directed mechanical ideals; he has been abused, hectored, discouraged and allowed to become a part of the flotsam of ne'er-do-wells.

Vital statistics comprising such data as Dr. Taylor suggests, among which are baby records of growth, development, physical and physiological peculiarities, etc., including also data of early childhood and its distinctive traits and idiosyncrasies, would furnish a first discriminative basis for educational outlook. Following this up with similar data of kindergarten and grade schools, in connection with such devices for testing mental quality as the

Binet Scale, the intelligent teacher has at command a ready means for differentiating the school work so as to insure from it a degree of efficiency which in the past has been quite out of the question. Such school statistics, made a part of the permanent records of the school, are at once available, not only as they relate to school pedigrees, but might readily become part of the vital statistics of the city, the state or the nation.

*But the difficulties involved!* To be sure there will be some difficulty in securing such statistics, and considerable labor as well. But they are not insuperable; they are not so difficult as may be supposed. Such data are already available in many schools. I have direct information as to the existence of such data in the schools of Pittsburgh, Rochester, New York City and others, where for several years these facts have been critically compiled and filed as a part of the records of the schools, just as are data of grades, etc. One condition which greatly lessens the supposed difficulty of such vital records is that of medical school inspection. This has now become a recognized part of all progressive school direction. And while as yet it may be chiefly concerned with such physical problems as teeth, tonsils, nose, eyes, ears, etc., yet there is no good reason why it may not include some note of mental traits, idiosyncrasies, etc. But further, it is now well known that in some of the better schools there are already provided child-study laboratories equipped with all necessary facilities for critically measuring mental qualities, among which are inquiries into heredity and antecedents.

Now to revert to the question of educational betterment. Let it be recognized at once that education is not *creator*, but *guide*. Educability is largely a question of innate mental constitution, which fundamentally is determined by brain structure and its correlations. Hitherto our only means of forming an estimate of educability has been that of experiment. Try out the subject by a dozen years of school life; then pass him on to the college; possibly what the schools failed to do some academic legerdmain of a college pro-

fessor may achieve! But the experiment usually serves only to continue through four years further a task which a brief glance through the school pedigree would have shown to be hopeless against hope. Education must in some way have its basis of selection and differentiation no less efficient than has been that of organic nature. One of the most hopeful of these means, so far as the writer can perceive, is through what may be designated as educational eugenics, the application of the principles of eugenics to problems of mind to the function of the schools, and pre-eminently to the college and university, in the same general way through which we are presuming to secure better social and racial germ plasms.

Assuming what is now generally conceded, that all human characteristics are inherited in probably equal degree, and this must include mental traits and aptitudes, then it is not utopian to anticipate the existence of potentialities of intellect which it may be possible to distinguish early in development, if indeed they may not be predicted on some basis such as Mendelism, and which may serve as an index of fitness for or against prospective scholastic eminence of such nature as to warrant encouragement or inhibition, as the case may be. This does not imply that all educational effort need be intercepted; to the contrary, it means rather differentiation of aims and methods. One may give no promise whatever of fitness for distinctively literary or scientific or pedagogical education, yet may be safely directed toward technical, vocational or industrial education. In other words, our program, like that of eugenics in general, should be selective in both a positive and a negative sense; fitness should be sought and fostered in every reasonable way, while the unfit should be deflected or diverted into avenues in which some outlook may prompt specialized training adapted to such betterment as may be within realization.

Let me close as I began, with a call for ampler and more critical vital statistics. They are needed in almost every phase of our complex modern social and civil life. They

can be made contributory to health, to moral and social conservation, and, as it seems to me, to educational progress toward a degree of efficiency and excellence for which it will no longer be necessary to apologize or explain.

#### TO TRACE THE LINES OF FORCE IN AN ELECTROSTATIC FIELD

Mr. R. F. D'Arcy describes an arrangement for tracing the lines of force of an electrostatic field in *Nature*, of March 20. Mr. D'Arcy's method is to support a metal ball at the top of a tall glass tube standing upon a float in a tray of mercury. Then, according to Mr. D'Arcy, the insulated ball follows the horizontal lines of force of the electric field between the properly placed terminals of a large electric machine.

Another method for tracing the lines of force in an electric field is described by Mr. B. M. Neville in *Nature* of April 3. Mr. Neville simply allows a scrap of cotton-wool to fall between the knobs of an electric machine. As soon as the bit of cotton-wool touches one of the terminals it becomes charged and moves off rapidly along a line of force.

The most satisfactory method known to the writer for tracing the lines of force in an electrostatic field is to suspend a toothpick by fine thread from the end of a long handle. When placed in the electric field the suspended toothpick behaves exactly like a compass in a magnetic field, and points in the direction of the field.

The method suggested by Mr. D'Arcy is open to the objection that an insulated metal ball does not, in general, tend to move along the lines of force in an electric field. The objection to Mr. Neville's arrangement is that the piece of cotton-wool moves too rapidly.

W. S. FRANKLIN

#### HIGH SCHOOL BOTANY

THE fact that an idea is a decade old is not necessarily a recommendation for it; but if it

remains in use after that time it is evident that it has worn well in at least one person's head. The present standard secondary course in botany has been in use in a large part of the United States for somewhat more than that time. At about the time it congealed into a fixed and generally understood course, I was teaching both college and preparatory botany in the University of West Virginia. As a teacher of botany, I was naturally much interested in the subject and took advantage of every opportunity to examine its workings. At the same time, I took care that none of my own students failed to get a decent familiarity with botany as it had previously been taught in the high schools; that is, with a knowledge of the flowering plants growing in the vicinity. As to the wisdom of including the study of individual flowering plants, my opinion has grown stronger with the years.

During the last seven years I have seen and overseen a very large amount of botanical teaching, including the work of more than twenty teachers. In two high schools and in the work given students of high school grade in the College of Agriculture of the University of the Philippines, the course has been as outlined in Bulletin 24 of the Insular Bureau of Education. This course is really general botany, including the general facts and principles of morphology and physiology, including also drill in the determination of plants by means of keys, and the preparation of an herbarium of fifty determined species. In a considerable number of high schools where the teachers had had the usual first year of college botany and no other preparation in the subject, the outline in this bulletin was found not to be an adequate guide for their work, and the course given was accordingly as near as they could come to the standard high school course, with the help of one or another of the texts in most general use in the States. All possible assistance, including the distribution of numerous determined plants, was given these teachers, in the attempt to make their teaching "alive." So much depends upon the teaching ability of the teacher that a comparison of results even when judg-

ment is based on familiarity with the subsequent work of a large number of students is not sure to be fair. But it certainly has been the case here that the students who were given instruction modeled after the standard American course have on the whole proved less interested in the subject, and less familiar with it, than those whose course had followed the local outline.

The students in the latter course get a firsthand knowledge of the plant cell, of the characteristic tissues of the higher plants, and of some of the typical plants illustrating the course of evolution. They learn accuracy, if the teacher teaches it, very much as they would in some other course. They are taught to think; enough for instance to be able to explain why the great groups of plants are characterized by their reproductive structures. They get a better idea of the variety and resourcefulness of nature than American students can be given, but this is because so many of the things we used to have to take on faith are growing about them. Also, and this is the characteristic of the course, each student becomes better acquainted with a considerable number of plants which he is already used to seeing, by determining them with a key and preparing them for his herbarium.

The teaching of botany should serve several uses. It should teach accuracy in observation and in depiction. It should help to create the habit of accurate thought. It should equip the students with a considerable amount of practical information. It should also give them an interest in the subject, which will stay with them after they get their credit and leave the class room. The standard course is essentially inadequate in two respects. It does not convey such information, which will be useful to many of those who have taken it, as it well might do. And it does not give the majority of those who take it an interest in the subject which will abide with them. The reason for the latter failure is that the course does not deal as it should do with things which are already familiar and interesting to the student, and does not include exercises of a kind which most of the students can have anything to do with after they leave school.

An interest in plants is a natural one. Plants are everywhere about us, and are useful in many and exceedingly important ways. The botanical teaching of the last ten or fifteen years has been missing its opportunity to serve and take advantage of this interest, by busying itself too exclusively with plants which most people never see except in the class room, and in which they have no practical interest.

The old course of study made better use in many respects of one term than the newer course has done of a year. It left much to be desired and the newer course made up its shortcomings; but it did this at too great an expense when it threw away the familiarity with the different kinds of common flowering plants, and the excursions, and the love of the woods which the students gained in old-time classes. There are hopeful signs of a backward swing of the pendulum. And it is well that this come before field botany is quite forgotten.

E. B. COPELAND

#### INDOOR HUMIDITY

TO THE EDITOR OF SCIENCE: Notwithstanding the conclusions reached in Dr. Ingersoll's interesting letter on this topic, something may perhaps be said in favor of a humidity considerably higher than 40 per cent., and nearer the 66 or 70 per cent. favored by "most authorities."

The writer has made experiments similar to those of Dr. Ingersoll, but with the following differences: gallons evaporated per day, 18 to 20, instead of 25 or more; volume of house actually served by the hot and humid air supply, 17,000 instead of 20,000 cubic feet; humidity maintained with comfort, over 60 per cent., instead of 40 per cent. Another important factor, and there are yet more, is that of house temperature. Unfortunately, Dr. Ingersoll has omitted any mention of this; but, judging from common American practice, one may, perhaps, assume a day temperature of 70°. Now in a Scots household, such as the writer's, a temperature nearer 60° is

thought more comfortable, and was that aimed at in our experiments. And herein enters the most interesting feature of the case, that the weight of water present per cubic foot, and hence the possible amount of dew deposit, is approximately the same with 40 per cent. saturation at 70° as with 60 per cent. saturation at 60°. Thus, after all, those at least of the authorities that are European may not be so far wrong in their estimate, and, truly, one does like to say a little, if only occasionally, in favor of the authorities.

The writer would agree most heartily with Dr. Ingersoll in the statement that any serious effort to raise the indoor humidity is very well worth while.

#### SCIENTIFIC BOOKS

*The Purchasing Power of Money; Its Determination and Relation to Credit, Interest and Crises.* By IRVING FISHER, assisted by HARRY G. BROWN. New York, The Macmillan Company. 1911. Pp. xxii + 505.

Although Irving Fisher is a good propagandist and can use arguments which appeal to the man in the street, his reasoning is based upon critical, logical, scientific analysis. One of the propositions which he has recently been actively promoting is international monetary reform looking toward the elimination or restriction of those disastrously wide variations in prices which may be due to the irregularities of the world's gold production. The principles upon which his suggestions for regulating the general price level are based are expounded in his "Purchasing Power of Money." An early proficiency in mathematics and interest in the mathematical theory of prices has led him naturally to a quantitative or quantity theory of money which he builds up with a deep knowledge and appreciation of scientific method. This attitude is a justification for SCIENCE to show an interest in his work which it could hardly exhibit in the case of ordinary studies in economics.

Fisher starts from the obvious identity that what is spent per annum is equal to what is spent. If  $E$  be expenditure in cash and  $E'$  expenditure by check, we have

$$E + E' = (E + E').$$

Now if  $M$  be the amount of money in circulation, the average velocity  $V$  of circulation or rate of turnover of this money per annum may be defined by the equation

$$E = MV;$$

and if  $M'$  be the amount of deposits subject to check, the average velocity  $V'$  of turnover of deposits may be defined by

$$E' = M'V'.$$

Further, if  $Q_i$  be the quantity of a substance  $i$  which is bought and  $p_i$  the price,  $p_i Q_i$  will be the amount spent in this transaction. Total expenditure ( $E + E'$ ) during the year will be the sum  $\Sigma p_i Q_i$  of the various products  $p_i Q_i$  for the transactions of the year; or

$$(E + E') = \Sigma p_i Q_i.$$

This equation may be modified by the introduction of the total trade  $T$  for the year and the average price  $P$ . Then

$$\Sigma p_i Q_i = PT,$$

and the fundamental identity becomes

$$MV + M'V' = PT, \quad (1)$$

which is the *equation of exchange*<sup>1</sup> (Chaps. I.-III.).

Such a mathematical identity is, as every one knows, a mere truism whose validity nobody should be rash enough to dispute. It might therefore be thought, and it is apparently the idea of many, that, being a truism, the equation is worthless, that nothing more can be obtained from it than has been put into it. This opinion has been somewhat of a

<sup>1</sup>This simple form of the equation applies only to self-contained communities where each transaction is settled during the year. The author, however, discusses (p. 370 ff.) the modifications necessary when unsettled accounts and intercommunal trade are present, and comes to the conclusion that the changes are insignificant in the case of the United States.

stumbling block relative to all mathematics, and even such a prince of mathematicians as Poincaré did not think it beneath him, in his philosophizing moments, to try to explain why mathematics can really amount to something, why it does give results which are valuable, why it is really creative. We need not enter upon that question here; we may admit that by proper discussion and transformation mathematical identities do reveal important relations not obvious in the original form of the identity. Let us admit the same in regard to the identity (1).

We now have under our eyes six separate elements,  $M$ ,  $M'$ ,  $V$ ,  $V'$ ,  $P$ ,  $T$ , entering into the equation of exchange, and we may focus our attention upon the effects produced upon certain of these elements by supposed variations in the others. For instance, if the amount of trade  $T$  and the velocities  $V$ ,  $V'$  of circulation of money and deposits remain constant from year to year while the amounts of money  $M$  and of deposits  $M'$  increase, it follows indubitably that the general price level  $P$  must rise. On the other hand, if  $M$ ,  $M'$ ,  $V$ ,  $V'$  remain constant while trade increases, the level of prices must be lowered. As a matter of fact the statistics for the United States for 1896 and 1912 are as follows:

	$M$	$M'$	$V$	$V'$	$T$	$P$
1896 ...	0.88	2.71	18.8	36.6	191	60.3
1912 ...	1.70	8.15	21.0	53.0	435	107.6

If we regard the price level  $P$  as the passive element, the effect, and the other elements as causes,<sup>2</sup> we shall attribute the rise in the price level chiefly to the great increases in deposits subject to check and in their velocity; for the product  $M'V'$  has about kept pace with the increase in trade, whereas  $M'V'$  has greatly outstripped it.

When it is a question of such actual figures as these, we have reached a stage somewhat remote from the equation (1) in the sense in which it was originally set up. Originally  $MV$  stood merely for the expenditures

<sup>2</sup>The author gives reasons to justify this assumption.

$E$  of cash, which would naturally be impossible to calculate directly; now  $MV$  stands for an estimate of these expenditures obtained by a searching analysis of available financial data; that is, the evaluation of  $E$  is indirect. The same is true of  $M'V'$  and  $E'$ . And the elements  $P$  and  $T$  are likewise found by diligent compilation and discussion of commercial data instead of by direct quest among the buyers and sellers. Such a change of aspect is found constantly in the correlation of theoretical and experimental physics. An equation is set up by a series of definitions or demonstrations. No amount of data can prove the equation; its validity is *a priori*. But the need of an experimental verification of the equation is none the less great; for in the applications to practical problems it is precisely such experimental data which must be used in the equation; and unless proper means of evaluating the terms of the equation are found, the importance of the theory is nil.

The author examines in lucid detail the various interrelations of the six elements which enter the equation of exchange. He comes to the conclusion that normally the element  $P$  may be regarded as passive, as the effect of the other elements, and that normally the ratio  $M'/M$  of deposits to circulation tends to constancy. He then goes on to an exhaustive discussion of what happens in transition periods where prices are rapidly rising (or falling) and where a certain amount of abnormality enters (Chap. IV.). The use of the word normally in the statement that normally the ratio  $M'/M$  tends to constancy seems rather unfortunate. The ratio  $M'/M$  has increased more or less steadily<sup>3</sup> for the United States from 3.1 in 1896 to 4.8 in 1912, and according to the author's estimate<sup>4</sup> for the whole gold-standard world the ratio will increase from 1.25 in 1911 to 2.25 in 1926. Thus the whole period of thirty years must be

regarded as abnormal. With this use of the word it might well be that most periods are abnormal. We would not dispute that in the cycles between successive crises there should be certain periodic variations of the ratio, and that sudden changes in the world's gold production should bring about other erratic variations, and it is these two things that the author seems chiefly to have in mind; but it seems evident that a certain secular increase in  $M'/M$  should be expected to accompany normal advances in banking facilities and the attendant increase in use of these facilities by the public.<sup>5</sup>

The refined quantity theory of money is contained in the equation (1) where all the elements except  $P$  are considered as independent variables; it is a much cruder theory which is based upon the assumed constancy of  $M'/M$ . No careful reader of Fisher's work will fall into any crude errors or attribute such errors to the author; but there are enough careless readers, who may seize upon the phrase "quantity theory of money" and be led into useless discussion forgetful of the developments of Chaps. VIII. and XII., that we could wish the author had made less of the "normal" dependence of  $M'$  on  $M$ . Those who will but observe that in the equation of exchange for 1896 the term  $M'V'$  was about six times as great as  $MV$ , and in 1912 about twelve times as great, will see the great danger and instability introduced into the system by making the preponderating term depend upon the small one.

The ascription of the rapid rise of prices during the past fifteen years to the great flood of gold has become increasingly popular of late, particularly since the impressive symposium on the subject in the first volume of *Moody's Magazine*. A facile argument may be constructed, namely, that the more gold we have relative to other possessions the less valuable is any given amount of it to us and the

<sup>3</sup>In the table on p. 304 the value 7.77 for  $M'$  for 1904 seems to upset the steadiness; but this number should obviously be 5.77.

<sup>4</sup>*American Economic Review*, September, 1912.

<sup>5</sup>A leading trust company says that now ten women have a check account where only a few years ago only two had one, and uses this fact to attract further accounts.

more readily will we exchange it for other goods; hence prices of other goods, as measured in gold, must rise. Such an argument does not introduce the equation of exchange; it is based on a sort of value theory of gold, partly quantitative, but largely psychological. We must not forget that according to theoretical economics the equilibrium of exchanges and the relative prices of goods do depend on the marginal utilities of the goods, that is, upon the relative values of the final infinitesimal quantities of goods entering into the exchange as these values are estimated by the individual traders. The value theory or, better, the marginal utility theory is therefore fundamental and the above mentioned facile argument is qualitatively correct.

When, however, we desire to take the equation of exchange as fundamental and for a quantitative discussion this seems the readiest if not the only thing to do, we have to examine merely the effects of a flood of gold upon the various elements of that equation. Suppose that 258 grains of standard gold are mined and turned over to the government for coinage into \$10 or for exchange for a gold certificate of like amount. Then  $M$  is thereby increased to the extent of \$10. As  $V$  is about 20, there is a contribution of some \$200 to the product  $PT$ . If a half billion of gold were thus injected into the circulation in the United States each year, it would cause an increase of ten billion in  $PT$ . Now in recent years trade has been increasing here in the United States at the rate of some fifteen billions per year. The half billion of gold, practically the total world output per year, would therefore not suffice to maintain prices, to say nothing of advancing them, here in our own country if we added all of it to the circulation, and provided, of course, that we did not otherwise inflate the circulation.

Suppose, however, that the 258 grains of gold went into the reserves of a bank operating under a rule of 25 per cent. reserve against deposits. The quantity  $M'$  would then be swelled not merely by \$10, but by \$40, and as  $V'$  is in the neighborhood of 50, the term

$M'V'$  would be increased by something like \$2,000, ten times as much as the term  $MV$  was increased on the previous hypothesis. Hence an addition of 75 millions in gold to the reserve stocks of banks operating under a 25 per cent. ratio would swell the term  $M'V'$  by the fifteen billion requisite to keep pace with trade, and a greater increase of gold would more than keep the pace, it would force prices to rise. These figures are very rough and are cited merely to enforce the idea that it is the expansion of credit by the influx of gold into bank reserves, and not the increase of gold in circulation, which must be the chief cause in the rise of prices as determined by the equation of exchange. We make no attempt to take secondary effects into consideration.

In the last chapter of the work the author discusses the possibility of stabilizing the purchasing power of the dollar, that is, of maintaining an approximately constant price level. The scheme he there suggests for accomplishing this purpose has undergone successive modifications in a considerable series of printed papers or privately circulated monographs until its present form appears in an article only two months old.<sup>6</sup> Unfortunately he abandons his equation of exchange and proceeds with general arguments or special hypotheses which seem far from substantial foundation. Such a change in style may be necessary to make an impression on a general public, and it is only by making such a general impression that any actual change of standard of value could be made into law; but for a mathematician the way would have been better lighted had the equation of exchange been constantly in evidence.

Briefly, the plan is to have the various gold-standard governments of the world pay less for gold as the general level of prices rises. Thus instead of giving a dollar for 25.8 grains of coin-gold, the United States would require 27 or 30 grains in exchange for a dollar. The author has an elaborately worked

<sup>6</sup> "A Compensated Dollar," *Quarterly Journal of Economics*, Vol. 27, February, 1913.

out plan for changing the price of gold and for preventing the government from being at the mercy of gold speculators. He gives detailed tables and charts to show what, on certain assumptions, would have been the results if his system had been in operation for certain periods of years. His suggestions have called forth a very large number of commendatory comments from a great variety of persons eminently able to judge of their value from many diverse points of view. There seems to have been but small adverse criticism from any quarter. As for ourselves, untrained in such matters and deprived of the direct guidance of the equation of exchange, we will acknowledge that a bewildering vacillation is in possession of us, swinging us now to complete confidence in the plan, and again to absolute distrust of it.

At the present moment we are extremely pessimistic about the efficacy of Dr. Fisher's remedy. Statistics show very well that the term in the equation of exchange which causes the trouble is  $M'V'$ . To keep prices constant we have to keep the increase of  $M'V'$  sensibly equal to the increase of trade. Now if a gold miner has to take fewer dollars from the government for a given amount of gold, there is a slight diminishing of the increase of  $M$ , and if he deposits the gold certificate subject to check, there is a slight reduction of the increase of  $M'$ . But these small alterations of the increases of  $M$  or  $M'$  would make only an insignificant effect upon the equation of exchange. Of course, if the price of gold were lowered enough to shut down some of the gold mines, the effect would be of considerable magnitude, and thus ultimately the regulation might be accomplished. But this would be at a very much altered price of gold; for gold mining is a pretty profitable business. Moreover, it would probably be an extremely unstable stabilization of the dollar; we have only to look at the market for copper metal over a long series of years to see how violent are the swings of prices when regulation of demand and supply takes place through the closing down or opening up of the less efficient mines.

When the government requires more gold for a dollar all the gold certificates outstanding, though presumably redeemable in the new ratio for gold, are actually backed by less than the requisite amount. Within moderate limits there would be, as the author says, no danger in this arrangement. Indeed, there has been at times a great cry against the wastefulness of gold practised by the United States in keeping a great hoard at par with the gold certificates,<sup>1</sup> whereas if the gold were available for banking purposes, it would serve as the basis of an enormous credit. But this is precisely what we do not want if we are intent on keeping prices down. It would add much to the possible efficacy of Fisher's regulatory plan if the government were required to maintain all the gold certificates at par with the new weight of gold. The author, however, specifically states that this need not be required. The matter is not so important as it might be, owing to the smallness of the term  $MV$  in the equation of exchange.

What about the banks? If the government is not to keep its certificates at par with the new figure for gold, are the banks to be compelled to compute their percentage gold reserve on the new basis? If so, the scheme is not very sure of enthusiastic support from bankers. For instance, if a banker has deposits of one million dollars on which he must keep a reserve of 20 per cent. in gold, he has a reserve of \$200,000, or 5,160,000 grains in gold, at the present exchange ratio of 25.8 grains to the dollar. If the ratio is altered to 25.9 grains to the dollar and he is still required to keep a 20 per cent. reserve, he must add 200,000 grains, or \$775, at the old evaluation, to his reserve. This, so far as he is immediately concerned, is equivalent to leaving the exchange ratio for gold unchanged and raising his gold-reserve requirement to 20.0775 per cent. This would undoubtedly have the

<sup>1</sup> We believe we are right in saying that R. Goodbody once suggested that some of the evils of our inelastic currency system could be alleviated, if not remedied, by calling in the certificates and paying out the gold.

effect of absorbing to a certain extent the present oversupply of gold. It would scarcely be effective in keeping down the average price level until a far greater rise in the effective reserve requirement had been made.

The calculations by which the author shows that had his system been in vogue during the last few years the price level would have remained sensibly constant are based upon the assumption that a one per cent. rise in the amount of gold demanded for a dollar brings about a one per cent. fall in the price level. On a certain vague value theory of money this may appear reasonable, but from the point of view of the equation of exchange it is far from obvious. The one thing we must bear in mind is that  $M'V'$  must be kept under control, and to a less extent  $MV$ . The author would have done much better to stick to his equation and calculate what effect his proposition would have had upon the changes in  $M'V'$ . That would have been more scientific.

Lowering the price of gold could diminish the increase of  $M'$  in three ways. First, by slackening the output. The lowering would probably have to go a long way, however, before the slackening became considerable. Second, by diverting gold from banking uses into the arts. Whether the arts, which now consume only about one third the annual output as against two thirds which goes to monetary and banking uses, could well absorb a much greater quantity of gold unless the price were very much lowered is not evident. Third, by augmenting the effective reserve requirements, as above explained. What we must have is some sort of a sink for gold. Indeed, it occurs to us to suggest that without at all disturbing the ratio of exchange between gold and dollars, we could accomplish the desired regulation of prices by insisting upon the strengthening of reserves. Suppose all banks receiving deposits subject to check were compelled to maintain a 50 per cent. reserve on all new business beginning with 1914. An increase of 15 billions in trade would then call for 150 millions in gold instead of the much smaller

amount at present required. To make banking less profitable and safer might be easier and more directly effective than to discourage gold mining.

So much attention has been devoted to Fisher's plan for regulating the price level because the subject is actively under discussion all over the world, because Fisher has failed to maintain the scientific excellence with which he started out, and because he has apparently developed a method of attack which is better and surer than the one he uses. In view, however, of the almost unanimous indorsement he has received we feel very apologetic about these criticisms we offer.

Some parts of the work we have scarcely touched upon, parts which from a scientific point of view might seem to merit more notice in this weekly than the parts we have discussed. For instance, there is in Chap. X, an analysis of the best index numbers of purchasing power and in an appendix a masterly analytical treatment of the various types of index numbers which show the defects and the advantages of different types for different purposes. And in general there is much of excellent scientific value throughout the appendices. But we must pass it by, as we do much of the historical matter (Chap. VII.), and the discussion of indirect influences which exert secondary effects on the equation of exchange (Chaps. V.-VI.).

The arrangement of the book is very thoughtful toward the reader. Not only are the table of contents and the index exceptionally full, but there is a little foreword wherein readers of different types are instructed as to where they will find what they in particular are looking for. The mathematical work is relegated to the appendices, and so are the more subtle developments. The book should be read by everybody at all interested in any of the questions it treats.

EDWIN BIDWELL WILSON

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

*The Mesozoic Flora of Graham Land.* By T. G. HALLE. Wissenschaftliche Ergebnisse d. Schwedischen Süd-polar-Expedition, 1901-

1903. Bd. III., Lief. 14. Pp. 123. Pls. IX. Stockholm. 1913.

The recent renewed interest in Antarctic exploration, the discovery of the South Pole, the unfortunate fatality attending the English expedition, etc., have focused attention on this *terra incognita*. There is in this region so much in the way of possibility as regards the origins of floras and faunas, centers of distribution, and possible migration routes, that everything which tends to throw light on its past life is likely to prove of absorbing interest, and in this connection it is a pleasure to note the appearance of Dr. Halle's splendid memoir on the Mesozoic flora of Graham Land which is the first Mesozoic flora known from the Antarctic. Previous to the work of the Swedish South Polar Expedition our knowledge of the ancient Antarctic vegetation was extremely limited. The present report is based on a very large collection made, it is said, under conditions of the greatest hardship, by Dr. J. G. Anderson at Hope Bay, Graham Land. The material came from a single series of hard, dark, slaty rocks and is regarded as Middle Jurassic in age. The flora embraces 61 forms of which, however, nearly 20 have not been given specific names. They are distributed among the several groups as follows: Filicales 25; Cycadales 17; Coniferales 16; unknown 3. It is of interest to note that the Ginkgoales, which are so important and varied an element in the northern hemisphere, are entirely absent in the Antarctic, as indeed they are in the Gondwanas of India. *Podozamites*, which is so abundant and variable in the north, is absent from the Hope Bay collection and is represented only by fragments in the Indian localities. Cycads are abundantly present at Hope Bay but they are all small-leaved species, while the conifers were abundant in materials but not well preserved.

Although the author has made quite a number of new species—on the wise basis that it is better to give a new name that may ultimately become a synonym, than to lump doubtful material under an old name that later

may have to be divided—there are no less than 22 species previously known. Of these, 9 species are common to the Lower Oolites of England, 8 to the Upper Gondwanas of India, and 5 to the Jurassic of California and Oregon, with others which are scattered at various well-known Jurassic localities. The close relation existing between the Jurassic flora of Graham Land and other contemporaneous floras is certainly remarkable when considered in regard to its remoteness from these floras. In the nearest continent, South America, there are no floras of any importance that can be considered contemporaneous with the Antarctic one. Dr. Halle concludes as follows: "Though the closest argument is with the Jurassic flora of England, the resemblance to the Indian Upper Gondwana flora is nearly as great. The Hope Bay flora tends thereby to lessen yet more the differences between these floras and thus becomes another important illustration of the uniformity and world-wide distribution of Jurassic floras. This uniformity is all the more striking because of the pronounced differentiation of the world's vegetation into two different phyto-geographical provinces at the end of the Paleozoic, which difference would appear to have become almost extinguished in Jurassic time."

F. H. KNOWLTON

#### SPECIAL ARTICLES

##### THE PHYSICO-CHEMICAL CONDITIONS OF ANESTHETIC ACTION. CORRELATION BETWEEN THE ANTI-STIMULATING AND THE ANTI-CYTOLYTIC ACTION OF ANESTHETICS

THE anti-stimulating action of lipid-solvent and other anesthetics is well known. Irritable tissues become temporarily irresponsive when exposed to solutions of these substances in certain concentrations, which must not be too high—otherwise cytotoxic results, or too low—in which case irritability may be increased instead of decreased. The precise nature of the change in the irritable elements conditioning the loss of irritability remains obscure. The Overton-Meyer theory refers

anesthesia to a modification of the lipoids. But a reversible loss of irritability similar in all essential respects to anesthesia may be induced by substances which have no specific relation to lipoids—as salts of magnesium or calcium, acids in low concentration, non-electrolytes like sugar—and also by the electric current (anelectrotonus). From these facts we must infer that although a change of state in the cell-lipoids may induce anesthesia it is not the essential change. Some other more general process is involved. What is the nature of this process?

In studying the conditions of chemical stimulation in the larvæ of *Arenicola*—a free-swimming annelid trochophore, 0.3 millimeters long and abundant at Woods Hole—I was struck with the fact that solutions which stimulate the musculature powerfully, causing strong and persistent shortening to half the normal length, invariably cause an immediate and marked exit of pigment from the body cells. Among such solutions are pure isotonic solutions of sodium and potassium salts. The cells of the larvæ contain a yellow water-soluble pigment, which on death, or under other conditions associated with increased permeability of the plasma membranes (action of cytolytic substances, as saponin), diffuses into the medium and colors the latter a bright yellow. This pigment thus serves as a convenient indicator of permeability-increase. The strong stimulation caused by isotonic NaCl solution is thus associated with a marked permeability-increasing action. This is equivalent to a cytolytic or toxic action, for definite toxic effects, as shown by breakdown of cilia and failure of the larvæ to revive completely on return to normal sea-water, always follow even brief exposure to the pure NaCl solution. The stimulating, permeability-increasing and cytolytic actions of the solution thus show a definite parallelism.

Conditions that prevent the immediate stimulating action also prevent the permeability-increasing and toxic action. Addition of a little calcium or magnesium chloride, *e. g.*, to the NaCl solution has this effect. In such

mixed solutions there is little or no immediate stimulation or loss of pigment and the toxic action is greatly diminished. Stimulation and permeability-increase, with the associated toxic or cytolytic action, are thus simultaneously prevented by the calcium or other antagonistic salt.

Similar effects are seen if the organisms are briefly treated with magnesium chloride *previously* to being brought into the NaCl solution. Isotonic MgCl<sub>2</sub> solution causes neither stimulation nor loss of pigment. The musculature is rapidly anesthetized in this solution, and the animals remain rigid and without contraction, swimming slowly by the cilia which remain active. If the larvæ are then transferred to *m/2* NaCl no immediate effect is seen. Stimulation and loss of pigment are entirely absent, and correspondingly there is little immediate toxic action. The treatment with MgCl<sub>2</sub> has a protective or anti-cytolytic as well as an anesthetic or anti-stimulating (desensitizing) effect.

Similar effects are produced by lipid-solvent anesthetics. Larvæ exposed to a 0.7 v. per cent. solution of ether in sea-water are rapidly anesthetized. If then they are brought suddenly into pure *m/2* NaCl containing the same proportion of ether, no stimulation or permeability-increase is seen, and the toxic action is diminished as before; *i. e.*, recovery on return to sea-water is much prompter and more complete than after similar exposure to pure *m/2* NaCl without previous anesthetization. Direct transfer from normal sea-water to ether-containing salt-solution also causes little or no stimulation or loss of pigment. The anti-stimulating action in this case also is associated with or involves a marked anti-toxic action.

I have performed similar experiments with a large number of other anesthetics with the same general results.<sup>1</sup> In those concentrations which in sea-water produce typical reversible anesthesia, the anesthetic checks or prevents the immediate stimulating action of the salt

<sup>1</sup>For a detailed account of these experiments *cf. American Journal of Physiology*, 1913, Vol. 31, pp. 264 seq.

solution, and also its permeability-increasing action as indicated by loss of pigment. A corresponding anti-cytolytic or anti-toxic action is invariably found to be associated with these effects.

The following anesthetics have been used in these experiments: *alcohols*: methyl, ethyl, n-propyl, isopropyl, n-butyl, n-amyl, n-capryl; *esters*: ethyl acetate, propionate, butyrate, valerianate, nitrate; *urethanes*: methyl, ethyl, phenyl; chloroform, carbon tetrachloride, nitromethane, acetonitrile, benzol, toluol, xylol, phenanthrene, naphthalene; ethyl ether, chloretone, chloral hydrate, chloralose, paraldehyde, phenyl urea, acetanilide, phenacetin, methacatin.

Almost all of these substances have also been used by Overton in his investigations of anesthesia in tadpoles. In the case of *Arenicola* larvae the concentrations requisite for neuromuscular anesthesia are in all cases higher (usually from three to five times higher) than for the neuromuscular system of Vertebrata. Otherwise the relations observed in these experiments are closely similar to those found by Overton and other experimenters in this field. For homologous series (alcohols, esters) the anesthetic action increases regularly with the molecular weight—i. e., with the lipid-water partition coefficient. The anti-cytolytic or protective action always runs closely parallel with the anti-stimulating action. A well-marked protective effect is however often seen in concentrations which are insufficient for complete anesthesia.

The general fact that the anesthetic hinders or prevents increase of permeability indicates that the seat of its *essential action is in the plasma-membranes of the irritable tissue*. The characteristic permeability of the plasma-membranes of cells to lipid-soluble substances furnishes strong evidence that these membranes consist largely of lipid material. The lipid-solvents alter the membrane by changing the state of its lipid components; other substances may produce similar effects by changing the state of the other colloids of the membrane. In general these ob-

servations show that anesthesia is associated with an increase in the resistance of the membrane to the permeability-increasing action of the stimulating agency. I infer, therefore, that the essential condition of anesthetic action is a modification of the physical properties of the plasma membranes of the irritable elements, of such a kind that the membranes fail to undergo, under the usual conditions of stimulation, the increase of permeability essential to this process. This modification may be caused by lipid-solvents, salts or other substances; also by altering the electrical polarization of the membrane by an external electric current, as in anelectrotonus. Apparently any condition that renders the membrane incapable of rapid and reversible changes of permeability renders the tissue refractory to stimulation. On this view the parallelism between the antistimulating and anti-cytolytic actions becomes intelligible, since increased permeability is the condition of cytolysis as well as of stimulation. Substances or conditions that prevent the one effect will also prevent the other.

These observations have a direct bearing on the general theory of stimulation. They support the view that an essential feature of the stimulation-process is a well-marked increase in the permeability of the limiting membranes of the irritable elements. It is obvious that the problem of the nature of anesthetic action involves the problem of the nature of the stimulation-process, and study of the action of anesthetics thus forms one means of attacking this wider problem. Any constant physical modifications caused in the irritable elements by the anesthetic, coincidently with the loss of irritability, must furnish indications of the nature of the processes concerned in the response to stimulation. The above observations thus agree with those of Nernst and his successors, which localize the primary or critical process in stimulation at the semi-permeable membranes of the irritable elements. They indicate further that in stimulation the permeability of these membranes is increased. But changes of permeability must involve

changes in the electrical polarization of the membranes; and it seems probable that these variations in electrical polarization are more directly responsible for the characteristic special effects produced by stimulation—such as increased oxidation, contraction, and the other forms of response which vary from cell to cell.

UNIVERSITY OF PENNSYLVANIA

#### THE SOUTHERN SOCIETY FOR PHILOSOPHY AND PSYCHOLOGY

THE eighth annual meeting of the Southern Society for Philosophy and Psychology was held at the Johns Hopkins University, Baltimore, on Tuesday and Wednesday, April 8 and 9, 1913. Three sessions were held: one on Tuesday afternoon, one on Tuesday evening and one on Wednesday forenoon. On Tuesday afternoon at 5 o'clock the members of the society were invited to attend the university lectures on "Bergson's Doctrine of Time" given by Professor A. O. Lovejoy in the Donovan Room of McCoy Hall. The sessions were held in the lecture room of the biological laboratory, President R. M. Ogden presiding. The president's address, entitled "The Relation of Psychology to Philosophy and Education," was given at the session on Tuesday evening. Preceding this address, the local members of the society entertained the visiting members at a dinner at the Johns Hopkins Club, and after the address they entertained them at a smoker in the rooms of Professor Lovejoy. The following items were passed upon at the business meeting, which was held on Wednesday morning:

1. It was decided to hold the next meeting at Atlanta, Georgia, during the recess of the Christmas holidays, in conjunction with the meetings of the American Association for the Advancement of Science.

2. The following officers were elected for the year 1913: *President*, H. J. Pearce, Brenau College; *Vice-president*, A. O. Lovejoy, Johns Hopkins University; *Secretary-Treasurer*, W. C. Ruediger, The George Washington University; *Council for three years*, Bird T. Baldwin, Swarthmore College, and Josiah Morse, University of South Carolina.

3. The following were elected to membership: Professor W. H. Chase, University of North Carolina; Professor L. R. Geissler, University of

Georgia; Miss H. B. Hubberd, Baltimore; Miss E. D. Keller, Baltimore; Dr. Frank A. Manny, Baltimore Training School; Professor Mark A. May, Murphy College; Father Thomas V. Moore, Catholic University of America; Mrs. Jacob Taubenhaus, Newark, Delaware; Mr. Jacob Ulrich, Baltimore; Professor H. H. Williams, University of North Carolina.

4. The accounts of the treasurer were audited by a committee of the council and showed a balance on hand, April 9, 1913, of \$68.70.

5. Votes of thanks were extended to the authorities of the Johns Hopkins University for the use of the lecture room of the biological laboratory and to the local members for the dinner and the smoker.

#### THE ZOOLOGICAL SECTION OF THE MICHIGAN ACADEMY OF SCIENCE

THE nineteenth annual meeting of the Zoological Section met in the zoological lecture room of the University of Michigan at 9 A.M. and 1:30 P.M. on April 3, with Vice-president Peter Okkelberg in the chair. The meetings were well attended and the following program was read. Dr. Bertram G. Smith, of the Ypsilanti State Normal College, was elected vice-president and chairman of the Zoological Section for the coming year. Hereafter the meetings will be held on the Friday and Saturday after Thanksgiving.

"Factors Governing Local Distribution of the Thysanoptera," A. F. Shull.

"Results of the Mershon Expedition to the Charity Islands, Lake Huron Coleoptera," A. W. Andrews.

"Types of Learning in Animals," J. F. Shepard.

"The Lepidoptera of the Douglas Lake Region, Cheboygan County, Michigan," Paul S. Welch.

"Check-list of Michigan Lepidoptera. II. Sphingidae (Hawk-moths)," W. W. Newcomb.

"On the Breeding Habits of the Log-perch," Jacob Reighard.

"A List of the Fish of Douglas Lake, Cheboygan County, Mich., with notes on their Ecological Relations," Jacob Reighard.

"May the Remains of Adult Lepidoptera be Identified in the Stomach Contents of Birds?" F. C. Gates.

- "The Mitochondria," R. W. Hegner.  
 "The Unione Fauna of the Great Lakes," Bryant Walker.  
 "An Adult *Diemyctylus* with Bifurcated Tail," B. G. Smith.  
 "Notes on the Mollusks of Kalamazoo County, Mich.," Harold Cummins.  
 "Sarcoptid Mites in the Cat," Harold Cummins.  
 "The Origin of Continental Forms, III.," Howard Baker.  
 "An Ecological Study of the Birds of Manchester, Mich.," F. Gaige.  
 "Notes on Crustacea Recently Acquired by the Museum of Natural History of the University of Michigan," A. S. Pearse.  
 "Distribution of Multiple Embryos on the Blastoderm," O. C. Glaser.  
 "Nesting of Our Wild Birds," Jefferson Butler.  
 "The Factors that Determine the Distribution of *Boleosoma nigrum* in Douglas Lake, Cheboygan County, Mich.," H. V. Heimburger.  
 "Pedogenesis in *Myiastor americana* Felt.," R. W. Hegner.  
 "The Seminiferous Tubules in Mammals," G. M. Curtis.  
 "A Method of Producing Cell-like Structures by Artificial Means," E. W. Roberts.  
 "Some Notes on Rhizopods from Michigan," E. W. Roberts.  
 "Oxygen and Carbonic Acid Contents of Douglas Lake, Cheboygan County, Mich.," D. A. Tucker.  
 "Some Observations on *Asplanchna amphora*," D. A. Tucker.  
 "Some Abnormalities Observed in Proteocephalid Cestodes," G. LaRue.  
 "Some Observations on Intestinal Villi," O. M. Cope.  
 "Some Physiological Changes in the Lamprey Egg after Fertilization," P. Okkelberg.  
 "A Collection of Fish from Houghton County, Mich.," T. L. Hankinson.  
 "The Lagoons and Ponds of Douglas Lake, Cheboygan County, Mich.," H. B. Baker.  
 "The Shiras Expeditions to Whitefish Point, Mich." (1) "Birds," N. A. Wood. (2) "Mammals," N. A. Wood. (3) "Amphibians and Reptiles," Crystal Thompson and Helen Thompson.  
 "Notes on the Ornithology of Clay and Palo Alto Counties, Iowa," A. D. Tinker.  
 "A Check-list of Michigan Mammals," N. A. Wood.

"The Variations in the Number of Vertebrae and Ventral Scutes in the Genus *Regina*," Crystal Thompson.

"An Artificially Produced Increase in the Proportion of Male Producers in *Hydatina senta*," A. F. Shull.

R. W. HEGNER,  
*Secretary*

# SOCIETIES AND ACADEMIES

## THE NEW YORK ACADEMY OF SCIENCES

THE Section of Anthropology and Psychology met in conjunction with the New York Branch of the American Psychological Association on April 28, when the following program was presented:

### Afternoon Session, at 4:10 P.M.

Mr. A. E. Rejall: "Binet Tests in Schools for Incurables in New York City."

Mr. G. F. Williamson: "Some Individual Differences in Immediate Memory Span."

Miss Mabel Barret: "The Order of Merit Method and the Method of Paired Comparisons."

Dr. E. K. Strong: "Effect of Size and Frequency on Permanence of Impression."

Dinner at the Faculty Club of Columbia University, 6:00 P.M.

### Evening Session, at 8:00 P.M.

Dr. Clara Jean Weidensall: "A Comparison of the Records of the Criminal Woman and the Working Child in a Series of Mental Tests."

Professor J. McK. Cattell: "Families of American Men of Science."

Dr. A. T. Poffenberger: "The Influence of Strychnine on Mental and Motor Efficiency."

## PHILOSOPHICAL SOCIETY, UNIVERSITY OF VIRGINIA MATHEMATICAL AND SCIENTIFIC SECTION

THE seventh meeting of the session of 1912-13 of the Mathematical and Scientific Section of the Philosophical Society was held April 22.

Mr. Justus H. Cline presented a paper by himself and Professor Thos. L. Watson, entitled "Normal Faulting in the Cambrian of Northern Virginia."

Professor Chas. Hancock presented a report on the "Plants of the Southern Power Company."

Professor J. S. Grasty read a paper, by himself and Professor Thos. L. Watson, on "Barite Deposits of the Southern States."

## For All-Round Laboratory Use

Science teachers in leading colleges and schools endorse the high optical efficiency, durable construction and easy manipulation of

## Bausch <sup>and</sup> Lomb Microscopes

Our new Model F offers many practical and valuable improvements. Its long curved handle arm with a large stage provides unusual space for object manipulation. Stage is rubber-covered—completely, top, edges and bottom. Ample room is provided between the edge of fine adjustment head and the arm for free play of fingers.

**Price, Model F, \$31.50. Special Price to Schools.**

*Write today for copy of "School Equipment" Catalog*

**Bausch & Lomb Optical Co.**  
**409 ST. PAUL STREET ROCHESTER, N.Y.**

*The Superior Quality of Bausch & Lomb lenses, microscopes, field glasses, projection apparatus, engineering and other scientific instruments, is the product of nearly Sixty Years of Experience.*

# Weiss Electro-Magnet

Made by Société Genevoise

These electromagnets are made in four different sizes to meet all laboratory requirements.

The coils are water cooled and as shown in the illustration are mounted on the pole tips concentrating the magnetic field at that point. The pole pieces may be separated by a micrometer screw and the distance between them read to .1 of a millimeter.

Five different shaped pole pieces may be used. The magnet is also adapted for polarization and other attachments.

Duty free prices are very attractive.

WE have come together especially to take note of the fact that fifty years ago a number of prominent workers in the field of science founded the National Academy of Sciences, receiving a charter from the United States government. It would be interesting and instructive to call the roll of the founders and learn who they were, but it will suffice to refer to some of the most conspicuous among these or, perhaps it would be better to say, some of those whose names are most familiar to the present generation. High up on this honor list are Louis Agassiz, James D. Dana, Wolcott Gibbs, B. A. Gould, Asa Gray, A. Guyot, Joseph Henry, J. Leidy, J. P. Lesley, Benjamin Peirce, R. E. Rogers, W. B. Rogers, L. M. Rutherford, Benjamin Silliman, Jeffries Wyman and J. D. Whitney. Fifty names are included in the act of incorporation. Among those are several members of the United States Army and Navy, as for example, J. G. Barnard, J. A. Dahlgren, Charles H. Davis, John Rogers, J. G. Totten, and others holding positions in the United States Military Academy and the United States Naval Observatory.

A careful scrutiny of the list of incorporators will show that they can be classified under three heads. The majority were engaged in scientific researches and had reached results of value. They were the leaders among the scientific investigators of that day. Then there were those who had gained distinction by their services as engineers either in the army or navy; and a

<sup>1</sup> MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

<sup>1</sup> Delivered by the president at the anniversary meeting of the National Academy of Sciences, April 22, 1913.

third class was composed of heads of national institutions such as the United States Naval Observatory, Naval Academy, Military Academy and Coast Survey.

Section 2 of the act of incorporation provides that the academy "shall consist of not more than fifty ordinary members," and that the academy "shall have power to make its own organization, including its constitution, by-laws and rules and regulations." Nothing is said in regard to the qualifications for membership. This is equally true of the constitution and rules except that Article I., Section 1, of the constitution requires that "members must be citizens of the United States." It should, however, be noted that Article IV., Section 4, of the constitution contains this clause:

Each nomination shall, at the time of election, be accompanied by a written list of the original works of the nominee.

The reference is to nominations for membership, and the inference is clear that the nominee was assumed to have "original works" to his credit.

Whatever may have been the views of the incorporators, it has gradually come to be held that membership should stand for successful activity in the field of scientific research, the word scientific as here used meaning that which pertains to the natural sciences. But our predecessors did not intend to bind themselves to this meaning, as is clearly shown by the election of James Hadley in 1864, who, though a brilliant scholar, was certainly not distinguished for work in natural sciences; of G. P. Marsh in 1865; and later of Francis A. Walker and Richard Mayo-Smith.

As regards engineers who were prominently recognized in the early days of the academy the change of attitude that is worthy of notice is briefly this: While one who had accomplished some engineering

feat was formerly regarded as worthy of membership by virtue of that fact, now the view appears to prevail that only such engineers as have advanced their subject by original contributions should be recognized.

And, finally, it is no longer held that the heads of scientific bureaus or departments of the United States government should necessarily be made members of the academy, no matter whether they have been actively engaged in scientific research or not. It is evident therefore that the field of choice has gradually become narrower.

What was perhaps regarded as the most important part of the act of incorporation is contained in Section 3 and reads as follows:

The academy shall, whenever called upon by any department of the government, investigate, examine, experiment and report upon any subject of science or art, the actual expense of such investigations, examinations, experiments and reports to be paid from appropriations which may be made for the purpose, but the academy shall receive no compensation whatever for any services to the government of the United States.

This clause is still valid. The United States government may at any time call upon the academy for investigations, opinions and advice on any subject of science or art and this without charge for services.

In order the more clearly to understand the situation that existed in 1863 we should bear in mind two facts. First, there were at that time but few scientific bureaus forming part of the national government; and second, it was a time of war.

Perhaps it would be better to state these facts in the other possible order. Service to the government was uppermost in men's minds. If they could not help in one way, they could in another. What more natural than this willingness to place their knowledge and skill in scientific matters at the disposal of the government? This was an

act of patriotism, and patriotism was in the air. While engineers, astronomers and mathematicians were then well represented in the works of those who were serving their country in one capacity or another, it was a difficult matter for those in authority to secure authoritative opinions and advice in other branches of science. There was a gap to be filled. By granting a charter to a group of the leading workers in all branches of science on the terms under consideration the gap was filled in a most satisfactory manner. After that act there could no longer be excuse for not seeking scientific advice whenever it was desired or needed.

How did this work? An examination of the records shows that for a number of years after the National Academy was incorporated the government perpetually called for reports. Six such reports were made in the first year of the existence of the academy. The subjects were: "On the Protection of the Bottoms of Iron Vessels"; "On the Magnetic Deviations in Iron Ships"; "On an Alcohoholometer"; "On the Explosion of the Boiler of the United States Steamer *Chenango*"; "On the Use of Aluminium Bronze for Cent Coinage"; "On Wind and Current Charts and Sailing Directions." In 1865 there were two reports; in 1866, four; in 1867, two, both of which are worthy of special mention. They are "On the Improvement of Greytown Harbor, Nicaragua," and "On Galvanic Action from Association of Iron and Zinc." In 1868 there were two. In 1870 there was one report "On the Protection of Coal Mines from Explosions by Electricity"; another "On Removal of Ink from Revenue Stamps"; and a third "On Silk Culture in the United States." In 1875 and 1876 there was only one each. Then in 1878 there were several important reports—six in all—among them one "On

Proposed Changes in the Nautical Almanac"; another "On the Use of Polarized Light for Determining Values of Sugars"; another "On the Measurement of the Velocity of Light" and another "On the Preservation of the Writing of the Original Declaration of Independence." While there have been important reports on important subjects since 1878, it is undoubtedly true that of late years the academy has been called upon less frequently than in the early years. At first the officers of the national government took the matter seriously, and this was to the advantage of the country. But with the multiplication of scientific bureaus supported by the government the need of help from the academy has become less and it is true that some of the subjects already mentioned, and others not mentioned, could have been reported upon by one or another of the existing bureaus had they been in existence at the time. But, even as matters now stand, there is ample room for the kind of activity which was in the minds of the founders. Large questions of a scientific character present themselves from time to time, and it is hard to conceive of a better method of dealing with such questions than that under consideration. In this connection it should be borne in mind that advice, even good advice, is not always heeded. Indeed it may happen that it is treated almost contemptuously. This is well illustrated by an actual case which deals with an important governmental problem. Owing to its importance this case may well be treated of in some detail.

The sundry civil act, approved May 27, 1908, requests the National Academy of Sciences to consider certain questions relating to the conduct of the scientific work under the United States government, and to report the result of its investigations to Congress. In order that the subject may

be clearly understood the language of Section 8 of the act referred to should be quoted:

*Sec. 8.* The National Academy of Sciences is required, at their next meeting, to take into consideration the methods and expenses of conducting all surveys of a scientific character and all chemical, testing and experimental laboratories and to report to Congress as soon thereafter as may be practicable a plan for consolidating such surveys, chemical, testing and experimental laboratories, so as to effectually prevent duplication of work and reduce expenditures without detriment to the public service.

A committee was promptly appointed and that committee gave serious and prolonged attention to the subject. In due time the committee submitted its report to the council of the academy. The council having approved, the president transmitted the report to the Speaker of the House of Representatives and the presiding officer of the Senate. Everything was done in proper form. The president of the academy congratulated himself on the personnel of the committee which he had appointed, upon the report and upon the fact that the academy had performed an important duty and had been, as he thought, of real service to the national government.

It were well perhaps to close the account of the incident at this point, but unfortunately the moral would be lost, and the only object of telling the story at all is to point the moral. Well, what happened next? It is not necessary to go into detail. The result was humiliating to the committee that drew up the report. That report seems to have been promptly pigeonholed. It is certain that, so far as we have any information on the subject, it was not given serious consideration by Congress. And yet whatever may have been its imperfections that report represented the views of a group of eminent men of science who had devoted much time and thought to the

study of the problem before them and who at the request of the President of the United States had been given every opportunity to learn the facts. Such an experience need not dishearten. The charter still holds good, and accordingly, the academy stands ready, whenever called upon by "any department of the government," to "investigate, examine, experiment and report upon any subject of science or art." As time passes it will come to be recognized more and more clearly by those in authority that the scientific method is the one most likely to lead to results of permanent value. Briefly defined, the scientific method consists in studying the facts and then drawing the most logical conclusion from these facts. It is most desirable that our government should utilize to a greater and greater extent this method which is free from partisanship and has only truth to serve. In the long run the influence of the National Academy upon affairs of government must be felt. Far-sighted statesmen must see and do see that it is well for the country to have a body of workers in the field of science connected in some way with the government, and the day will come when this will be recognized more clearly and more generally than it is to-day. The question is not what is best for the academy? It is, what is best for the country? May we not hope that in the near future Congress will see its way clear to emphasize the importance of the connection between the government and the academy by providing it with a proper home which can serve as a center of general scientific activity? This subject has again recently been brought to the front and there is a possibility that favorable action may be taken.

By an act of Congress approved June 20, 1884, the National Academy of Sciences was "authorized and empowered to receive

bequests and donations and hold the same in trust, to be applied by the said academy in aid of scientific investigations and according to the will of the donors."

The funds under the general management of the academy and their purposes will now be stated in their chronological order.

1. *The A. D. Bache Fund*.—This amounts to over \$50,000. It was provided by the will of Alexander Dallas Bache, one of the charter members and the first president of the academy, who was for many years superintendent of the United States Coast Survey. The academy is trustee, and the income is applied to the prosecution of researches in physical and natural sciences.

2. *The Joseph Henry Fund*.—This fund of \$40,000 was contributed by a number of friends and admirers "as an expression of the donors' respect and esteem for Professor Joseph Henry's personal virtues, their sense of his life's great devotion to science with its results of important discoveries and of his constant labors to increase and diffuse knowledge and promote the welfare of mankind." The income was to be paid to Professor Henry during his life, and after his death to his wife and daughters, and after the death of the last survivor the fund is to be delivered to the National Academy of Sciences, "the principal to be forever held intact and the income to be from time to time applied by the said National Academy of Sciences in its sole discretion to assist meritorious investigators, especially in the direction of original research." Happily this fund has not yet come into the possession of the academy. It is not necessary to remind this audience that Professor Henry was for years the secretary of the Smithsonian Institution.

3. *The J. C. Watson Fund*.—This amounts to \$25,000, and was provided by the will of

Professor J. C. Watson, a distinguished member of the academy, who died in 1880. The income "shall be expended by said academy for the promotion of astronomical science." It is also provided "that the academy may, if it shall seem proper, provide for a gold medal of the value of one hundred dollars, from time to time to the person in any country who shall make any astronomical discovery or produce any astronomical work worthy of special reward as contributing to our science." Five medals have thus far been awarded, the recipients being B. A. Gould, Edward Schönfeld, Arthur Auwers, Seth C. Chandler and Sir David Gill.

4. *The Henry Draper Fund*.—In 1883 Mrs. Henry Draper, widow of Henry Draper, late our honored member, presented to the academy a fund of \$6,000 for the establishment of a gold medal to be awarded by the academy every two years to the individual in this or any other country who makes the most important discovery in astronomical physics. This fund now amounts to \$10,000, as, in accordance with the wish of the donor, the income, above what was required to provide the Draper medals, was for a time allowed to accumulate and was added to the principal until this amounted to \$10,000. At present the excess of income is available for purposes of research in the line of astronomical physics. The Draper medallists named in chronological order are S. P. Langley, E. C. Pickering, H. A. Rowland, H. K. Vogel, J. E. Keeler, Sir William Huggins, G. E. Hale and C. G. Abbot.

5. *The J. Lawrence Smith Fund*.—In 1884 Mrs. J. Lawrence Smith, widow of one of our honored members, presented to the academy the sum of \$8,000, the object of the gift being to promote the study of meteoric bodies, a branch of science which Dr. Smith had pursued with marked suc-

cess. In accordance with the wishes of the donor it was decided that a gold medal to be given as a reward for original investigations would be most appropriate. Any excess of income above what is necessary for the striking of the medal "shall be used in such manner as shall be selected by the National Academy of Sciences in aid of investigations of meteoric bodies to be made and carried on by a citizen or citizens of the United States of America." Only one J. Lawrence Smith medal has been awarded. The recipient was H. A. Newton, "for the investigation of the orbits of meteors." The income has otherwise been used to aid investigations, especially those of Professor Newton.

6. *The F. A. P. Barnard Medal.*—This was provided for by the will of the late F. A. P. Barnard, one of the incorporators of the academy, and, at the time of his death the president of Columbia College (now Columbia University). The fund is controlled by the trustees of Columbia University. They "shall cause to be struck, with suitable devices, a medal of gold, nine tenths fine, of the bullion value of not less than two hundred dollars, to be styled 'The Barnard Medal for Meritorious Services to Science,' and shall publicly announce that a copy of the same shall be awarded, at the close of every quinquennial period . . . to such person, whether a citizen of the United States or of any other country, as shall, within the five years next preceding, have made such discovery in physical or astronomical science, or such novel application of science to purposes beneficial to the human race, as, in the judgment of the National Academy of Sciences of the United States, shall be esteemed most worthy of such honor." In accordance with these terms the academy has recommended to the trustees of Columbia University the award of the Barnard medal as follows:

In 1895 to Lord Rayleigh and William Ramsay "for their brilliant discovery of argon, a discovery which illustrates so completely the value of exact scientific methods in the investigation of the physical properties of matter."

In 1900 to Wilhelm Conrad Röntgen, "for his discovery of the X-rays."

In 1905 to Henri Becquerel "for his discoveries in the field of radioactivity."

In 1910 to Ernest Rutherford "for meritorious services to science resulting especially from his investigations of the phenomena of radioactive materials."

7. *The Wolcott Gibbs Fund.*—When Wolcott Gibbs, who was one of the incorporators of the academy and at one time its honored president, reached the age of seventy in 1892 a number of friends presented him \$2,600 to establish a fund bearing his name, the income to be devoted to aiding in the prosecution of chemical research. Dr. Gibbs presented this fund to the academy, the income to be administered by a board of directors, who "shall have absolute and entire control of the disposition of the income of the fund, employing it in such manner as they may deem for the best interest of chemical science."

8. *The Benjamin Apthorp Gould Fund.*—In 1897 Miss Alice Bache Gould, daughter of the distinguished astronomer, Benjamin Apthorp Gould, one of the incorporators of the academy, who died in 1896, presented to the academy the sum of \$20,000 as a memorial of the life work of her father, the income to be used "for the prosecution of researches in astronomy."

9. *The Cyrus B. Comstock Fund.*—This now amounts to something over \$10,000 and is to be increased by accumulations of income until it reaches \$15,000. A part of the income is to be used to provide "once for every five years a prize in money to the bona fide resident of North America, who,

not less than one year nor more than six years before the awarding of the prize, shall have made in the judgment of the trustees the most important discovery or investigation in electricity or magnetism or radiant energy."

This gift was received in December, 1907, and the first Comstock prize will be awarded at the present meeting.

General Comstock was a distinguished engineer, and a member of the academy. He died in 1910.

10. *The O. C. Marsh Fund*.—Professor Marsh, for twelve years president of the academy, died in 1899. He bequeathed the sum of \$10,000 to the academy, "the income to be used and expended by it for promoting original research in the natural sciences." This fund has not yet become available.

11. *The Alexander Agassiz Fund*.—Alexander Agassiz, who was president of the academy from 1901 to 1907, died in 1910, and bequeathed to the academy the sum of \$50,000 unconditionally. No decision has yet been reached in regard to the uses to which this fund is to be put.

12. *The Agassiz Medal*, which will be awarded for the first time this year, was provided for by a gift of Sir John Murray.

While this account may have proved tedious to some of you, it seemed necessary for the purpose of giving a correct impression of the work now being carried on. The academy has sacred duties to perform. It will soon devolve upon the younger members to see that these duties are conscientiously performed.

The constitution provides that the academy shall hold one meeting in each year in the city of Washington and another at such place and time as the council may determine. Whatever may be said of the duties of the academy as the scientific adviser of the government and as a custodian of trust

funds, it must be acknowledged that it is through the agency of its regular meetings that its influence is mainly exerted. In this as in other matters, it is the subtle, the intangible, the spiritual that tells. Workers in the field of science are supposed by some, perhaps by many, to be incapable of recognizing the force of the intangible, and yet scientific work must inevitably lead to this recognition. It is impossible to weigh and measure the effect of the meetings upon those who take part. But that effect is felt none the less, and it is certain that those who attend are in the long run benefited—some in one way, some in another. This is not a subject that lends itself to profitable discussion. It may not be out of place, however, for one who has been a regular attendant for over thirty years to make public acknowledgment of the debt which he personally owes the academy for the opportunities it has afforded him of associating with and counting among his friends those whose earnest, honest work has been an inspiration to him and to the world. This association has been an inestimable privilege for which he is deeply thankful.

The work of the academy will continue; new and younger members will take up the work. Is it too much to hope that when the centennial anniversary is celebrated some of the members here present may be remembered as we to-day remember with gratitude the founders?

IRA REMSEN

---

#### THE RELATION OF SCIENCE TO HIGHER EDUCATION IN AMERICA<sup>1</sup>

THE half century which has elapsed since the founding of this academy has witnessed a radical change in the relations

<sup>1</sup> Address delivered before the National Academy of Sciences on the occasion of the semi-centennial celebration of its foundation.

between science and education. This change is equally marked in the professional training which prepares students for their several callings, and in the general training which prepares them for the duties and enjoyments of citizenship.

Fifty years ago the professional study of science in our universities was confined within very narrow limits—surprisingly narrow to those who see those places as they are to-day. There was no room for science in the schools of theology or of law. Schools of philosophy, in the modern sense of the word, had hardly developed. Even in schools of medicine, where the study of natural science in universities first gained a foothold, there was relatively little of scientific method, as we to-day understand the words, either in the teaching or in the study. There was much more learning of names of things than there now is, and much less learning of reasons of things; much more of tradition and much less of investigation. The anatomy and chemistry of the medical schools of those days were good sciences, as far as they went, but they generally did not go very far. As to the use made of science there is truth in the remark of one of my former colleagues that down to a recent day the three learned professions of theology, law and medicine had not advanced far beyond the old conception of the magic of the tribal medicine man, that the important thing for science to do was to find proper formulas of exorcism with which to banish evil spirits from their several realms of action.

Outside of the universities, a half century ago, things were little or no better. There was a small number of schools of engineering and a still smaller number of schools of chemical technology; but they did not form part of a large scheme of business training for the nation as a whole.

Most of the engineers had learned their profession in the field; most of the technologists had learned it in the shop.

All of this has changed during the fifty years of the life of the academy, and changed radically for the better. Our universities have developed scientific study in all their departments, and especially so in their schools of medicine and philosophy. Side by side with these university schools or faculties there have grown up colleges of engineering and technology, sometimes in connection with the university, sometimes outside of it, which lay a scientific foundation for many a calling that only a few years ago was thought to need no scientific foundation at all. The world has found a place for the scientific expert in every line, and is inclined to regard as the best school, not the one that has the most students, not even the one that can give the best general education, but that which in the different lines can train and furnish scientific experts of the highest rank and most varied knowledge.

For civilized nations have at last come to the conclusion that the old supposed antagonism between theory and practise was a misleading conception, and that the habit of drawing a sharp line between the theoretical man and the practical man was a pernicious one.

Fifty years ago a man who had obtained all his knowledge of his business by his own experience was habitually proud of the fact; he was, as the phrase went in those days, a self-made man who spent most of his time in worshipping his creator. He counted it a matter of superiority that he knew nothing except what he had found out himself and taught himself. To-day it is recognized that every practical man can learn much from the theorist; that there is room for the application of scientific principles in every department of life;

that the farmer, the manufacturer or the merchant, no less than the engineer or the physician, must prepare to avail himself of the theory which has been built up by investigators, which has been taught in laboratories and incorporated in books, if he would bring his practise up to the needs of the time.

Of all the conquests of modern science, there is none which, in my judgment, is more remarkable or significant than this conquest of current business opinion. We no longer draw a distinction between learned and unlearned professions. We have recognized that every profession and every trade, in order to be pursued to the best advantage, must be a learned one. None so complex as to be unable to get help from science; none so simple as not to need it. We have shaped our system of technical training accordingly; and we have learned to rate at their true worth the men and the places that can give training as research institutions, side by side with universities which make progress in such training possible.

Equally important, though of a different and perhaps less satisfactory character, has been the change in the scheme of our general education; in the choice of subjects and methods of teaching offered in preparation for the work of citizenship as distinguished from the preparation of each man for his business or calling.

The old course of study in our high schools and colleges consisted chiefly of classics, mathematics and metaphysics, with a little history and a few descriptive courses in natural science. Of scientific training in the modern sense it gave none, except to the unusual man whose mathematical tastes made the study of algebra and analytical geometry a means of scientific education in spite of text-book and instructor and class-room atmosphere, or

the still more unusual man who used his grammar and metaphysics as an exercise in closely ordered reasoning. The course, as a whole, was constructed for the student whose interests were in the past rather than in the present and the future. The training which it gave—good, in many respects—was a training in memory, in expression and in accuracy of apprehending language, one's own or another's, rather than in scientific method, as we understand it to-day.

There is on the facade of the main hall of a university which has done much for education in many lines, a representation of philosophy in a dominant central position—old-fashioned metaphysical philosophy—with the different sciences laying tribute at her feet. I suspect that this is not an unfair characterization of the views as to the place of science in education which prevailed among most college faculties a generation or two ago.

Now let me say right here that I do not for a moment overlook the advantages of the old system. It taught the boys to use books and find things out from books, and to expect to do hard work for that purpose instead of to have somebody else make it easy. This was a great merit, and the boys trained under the old system showed this merit. But college faculties were often blind to the particular kind of book learning that was most significant for human progress and which was of most concern to the living world outside.

For at the time when the academy was founded, and in the time since, chemistry and physics and geology and biology were becoming not only matters of importance to the experts in their several callings, as I have indicated, but subjects of real and dominant interest to intelligent men who were not experts, but who cared for knowledge and who cared for current history.

A large section of the world, an increasingly large section of the world, cared more for books that explained the tendencies of the present than for those that embodied the ideals of the past. Perhaps this movement may have gone too far and may have caused people to care too little for the ideals of the past, to overvalue scientific reading as compared with historical or literary reading. I shall not try to discuss whether it did or not. At any rate, a curriculum which was exclusively occupied with classics and philosophy ceased to meet the demands of grown men or the needs of boys, and the course of study in our colleges had to be remodelled accordingly. Each decade of the last fifty years has witnessed a gradual crowding out of classics from our older schools and colleges by subjects of new and more present interest, and a growth of new schools and colleges of a different kind, where science in varying forms is made the chief subject of attention and other matters relegated more or less to the background.

Now this increasing interest in science is a matter about which we all, members of the academy and guests of the academy, scientific men and literary men, may rejoice heartily. But how far the things that are called science always deserve the name of science, or how far the teaching of such subjects by present methods always deserves the name of education, is quite another question. Every school superintendent likes to stimulate the attention of his pupils by giving them the opportunity to see amusing phenomena with their own eyes, and if possible set them in motion with their own hands. Under some circumstances this may be the best kind of scientific training; under other circumstances it may be no training at all.

Nature study—to quote a phrase which is popular among educators of the present

time—is good if it is made the basis for teaching scientific methods, and bad if it is simply made a means of momentary amusement. Unfortunately, a large part of our school committees and school teachers think that the subject makes the science. They may not go as far as the author of “Murray’s Handbook to Spain,” who says that the mountains of that country, to quote his own words, “abound in botany and zoology.” But they are apt to assume that the picking to pieces of flowers is in itself botany, and that hearing a carbon disulphide mixture make a loud explosion marks progress in chemistry, and to act accordingly. A short time ago a school superintendent in one of our more newly developed parts of the country said he had to make a change because it was so easy to find thoroughly competent teachers of physics, but that so few of them ever knew any algebra.

Fifty years ago the members of the National Academy of Sciences who held seats in college faculties were occupied in protecting science against its enemies. I am not sure but what to-day their chief duty lies in protecting it against its friends. When the National Educational Association says that high schools should be allowed to omit the study of algebra and geometry and that the colleges should be compelled to accept for admission an equivalent amount of “science”—God save the mark!—it is time for the true friends of science to call a halt.

For the importance of scientific training to the student in our high schools and colleges is not due primarily, or in large measure, to the facts of physics or biology that he learns in the school. It is due to the training in certain habits of observation and deduction, in certain methods of hypothesis and verification, which he can get more effectively by a good course in science

than by one predominantly devoted to languages, where the scientific training is merely incidental. That the facts of physics or biology are more interesting to the student and to the world than those of Latin and Greek and have more obvious bearing on everyday life is a help to the teacher in securing the voluntary cooperation of the pupil; but it is far from being the fundamental reason why the subjects themselves are educationally valuable. It is not the subject that makes the course scientific; it is the method.

You have been good enough, Mr. President, to refer to my father's connection with the academy, and I for my part am glad to take the opportunity to say that he regarded his election to membership in this body as the greatest honor he ever received. I feel sure, therefore, that I shall be pardoned if I illustrate the point I have just made by reference to my father's teaching.

Fifty years ago the one course in the academic department of Yale College where modern science was really taught, was the course in freshman Greek. For my father, though he had the highest enjoyment of classical literature, was by training and temperament a philologist; and he taught the freshmen who came under him to take Greek verbs to pieces and compare and observe their parts and put them together again, and see what principles were involved in the analysis and synthesis, exactly as the botanist might have done with his plants or the chemist with his elements.

In those days chemistry and physics were taught in Yale College, as distinct from the Sheffield Scientific School, solely by text-books and lectures. Philology was taught by the laboratory method; and for that reason the freshman Greek course was a course in modern science and meant that to the pupils. The courses in chemistry

and physics widened the boy's knowledge of facts and doubtless encouraged many of them to get scientific training for themselves afterward; but the course in freshman Greek was a course in science, because the boys learned to do the things, both easy and hard, which are the heritage of the man of science.

Science is not a department of life which may be partitioned off from other parts; it is not the knowledge of certain kinds of facts and the observation of certain kinds of interest, as distinct from other facts and other interests; it is a way of looking at life and dealing with life; a way of finding out facts of every kind and dealing with interests as varied as the world itself,

Where each for the joy of the working, and each  
in his separate star,  
Shall draw the thing as he sees it, for the God of  
things as they are.

ARTHUR T. HADLEY

YALE UNIVERSITY

*SPEECHES AT THE ANNIVERSARY DINNER  
OF THE NATIONAL ACADEMY  
OF SCIENCES*

SPEECH OF THE RIGHT HONORABLE JAMES  
BRYCE

*Doctor Woodward, President Remsen and gentlemen:* I am very much touched by the kind words in which my old friend, Dr. Woodward, has introduced me to you, and I am more than grateful to you for the way in which you are kind enough to receive me. It does make one happy to be so received and to be assured that one has not lived in this country six years without having acquired some friendliness on the part of its people.

But, apart from that, gentlemen, I stand before you this evening as a rather unhappy man, because it is the last evening on which I am likely to have the privilege—at any rate, in an official capacity—of

meeting an audience of American men of science.

One of the most delightful parts of my sojourn in Washington has been my intercourse with your men of science. There is not any city in America—I doubt if there be any city in Europe—where so many men of eminence in science are assembled as live in Washington, and the gatherings which you have here, when the men of science from the whole of your wide country come together, have been among the most delightful experiences that I or any Briton has had in this country. I have had it also in Philadelphia and in New York, and I have had the pleasure of making the acquaintance of your men of science in many journeys all over the country; but this, after all, is the focus to which is gathered most of the scientific lights and leaders of the United States at stated intervals when you come together here.

And I can assure you, gentlemen, there is nothing I shall look back to with more pleasure, in so much of life as remains to me, as to the friendships I had formed with your scientific men and the inspiration I have derived from the ardor and energy with which they pursue the studies to which we are all so much debtors.

Dr. Woodward has suggested that I should say something about foreign academies, but my knowledge about foreign academies is, really, practically confined to my own country, for, whenever I have traveled abroad, it has rather been among the historians than among the men of science that my work has lain.

However, I should in any case feel a little doubtful about venturing to talk about scientific academies, knowing that, whatever else "science" means, Mr. Vice-President, it is supposed to mean knowledge; and if a man feels that he does not

know a thing, scientific people are the last to whom he should address his remarks.

I received at Oxford my literary education, and I remember "education" being defined by a very eminent professor there, who said: "What our Oxford education does is to teach our men to write plausibly about subjects they do not understand"—an art which we were in the habit of exemplifying by immediately beginning to write for the journals and reviewing books—whose authors knew infinitely more about their subject than we did—in a very superior manner, an experience which, however, is not confined to England.

The vice-president said, gentlemen, that he regarded men of science with fear and veneration. I share those feelings. I have veneration for the lofty and disinterested spirit which you bring to your work. I have fear for the enormous power you exercise.

You are really the rulers of the world. It is in your hands that lies control of the forces of activity; it is you who are going to make the history of the future, because all commerce and all industry is to-day, far more than ever, the child and product of science; and it is you who make these discoveries upon which, when they are applied by industry, the wealth and prosperity of the world depend. It is in your hands that the future lies, far more than in those of military men or politicians.

But I have another feeling besides fear and veneration. It is that of envy. I envy you your happy lives. Compare your lives with the lives of any other class. If the vice-president will permit me, I think the life of a man of science is a great deal happier than the life of a politician or the life of a statesman, who, as we know, is many pegs above the politician, because the politician is occupied, as the vice-president has said, in endeavoring to promote the

interests of his party and not the interests of his country; and I discovered, during my experience in the House of Commons in England, that a legislative assembly is the worst place in the world for the discovery of abstract truth.

Or, take the case of the lawyer. So far from seeking to discover the truth, in one half of the cases which he conducts, he is endeavoring to obscure the truth. Or, even take the case of the artist or the literary man, who has a subject to work upon, delightful and interesting in itself, in evoking from the stone, or by colors, shapes or forms of beauty, which will far outlive him; but these forms of beauty will profit him very little if they do not commend themselves to the popular tastes, and he is constantly under the temptation of doing something less good than he wishes, in order to meet the tastes of his patrons.

It is the man of science who has the really happy life. He is engaged in the discovery of the truth, and nothing but truth. The applause of the multitude is nothing to him. He is working for a mistress more exalted than any popular assembly or any multitude that we can conceive of. He is working for Truth herself, and for the future. He is consecrating his efforts to the highest task that God can lay before man, and in that he needs nothing but the sense of what he is adding to the sum of human knowledge, and he has the incomparable pleasure of feeling that the more he knows, the more the immense ocean of knowledge stretches itself out before him. The further he outlines any path into the untrodden solitudes of ignorance, and the more he blazes those paths and makes them paths of knowledge, the more he sees other paths branch out before him, leading further and further away into the realms which others after him will traverse.

In these things, friends, there are ele-

ments of pleasure and delight, elements also of independence, which I think no other profession can equal. I was tempted to add one other charm which your life has. It is the charm of poverty. I have sometimes felt inclined to wish, Mr. Vice-President, that Congress was a little more liberal to the scientific men who are working for Uncle Sam. But perhaps they are to be congratulated on being free from those temptations which beset wealth. Poverty, like other things, is good if you have not too much of it, because it saves one from the temptation of forgetting the end to the means, the temptation to which most of us, and, above all, those who are in search of wealth, succumb. You keep the end always before you, and you proportion your life to that end.

Still, I think you might, with advantage, not only to you, but, what is far more important, to the whole country—and it ought to be possible in a wealthy country like this—provide upon a more ample scale for those who follow science, and give science a more exalted position, by freeing the scientific man from any thought of domestic anxiety.

You enjoy in this country—I speak here of particular branches of science—some things which we, in England, greatly envy. Think of what the geologist or the botanist has before him here! We have been working for one hundred and fifty years upon the geology, and for more than that upon the botany, of our little island; but here you have the whole continent open to you, and any man of science on these subjects can make a reputation for himself by new work in new fields, such as is impossible for us in outgrown Europe.

Gentlemen, one word I venture to say about the scientific bodies of the continent of Europe. We have, in the Royal Society, the oldest of those bodies, and one which, I think, has always maintained the level

which it took in the great days when Isaac Newton was one of its members; and now there has sprung up all over Europe a host of other bodies pursuing science and following it into those infinite ramifications which modern science has discovered. Everywhere there you are welcome. One of the most delightful things of science is that it knows no divisions or allegiance to nationality. It is a republic in which there is no passport to greatness, except service and genius, and it is a republic of which every one is a citizen, and where every one has equal rights in every part of the world.

That has always been our tradition in England and in our Royal Society; and I know it is your tradition here, and I know what hearty welcomes you have always given to our men of science when they have come over here, and how refreshed and invigorated in spirit they have been when they have gone back to their own country.

Gentlemen, I can wish nothing better for any of us than that these comings and goings will be frequent, and I can assure you that it will always be a pleasure to the scientific men of England and Scotland to welcome you to their societies and to all their gatherings and universities. I hope that, more and more, these meetings will take place, and I can assure you that all you have achieved and all that you are achieving in so many ways on so many different lines for the advancement of knowledge, for the extension of human power that comes through knowledge, is followed with gratitude and admiration by the scientific men of Great Britain.

---

SPEECH OF DR. S. WEIR MITCHELL

*Mr. President, Mr. Vice-President, my brothers of the Academy:* I am, I presume, the victim of the after-dinner hour, as usual, and am well aware of the treachery of the tongue, and much prefer the loyalty

of the pen. I have, therefore, deliberately put on paper that which I want to say to you to-night, feeling that it will be much more probable that I shall interest you than if I trusted to my unassisted words.

I am, I presume, indebted to the liberal forbearance of time for the honor of being asked to speak to you this evening. It does not find me in the careless mood of after-dinner gaiety, nor is it possible to escape altogether from personal remembrances, which elsewhere than at this friendly board might entitle me to be relegated to what Disraeli called the "fatal time of anecdotage."

My diploma is dated August 25, 1865, three years after our foundation. It is signed by Dallas, Bache, Wolcott Gibbs and Louis Agassiz. Since then, one hundred and thirty-six of our fellowship have come and died, with an average duration of academic life of more than eighteen and a half years—very many with far less. This makes clear that in those earlier years our additions were of men older than those we elect now.

At present the liberal endowment of research opens the way to distinction for younger men, unembarrassed by the time-killing need to preach science as well as to practise it.

Between the mere words of our record—*elected—deceased*—you, who are familiar with our history, may read much that is written clear on the roll of scientific achievement.

Here are they to whom, from the depths of space, were whispered in the night watches its long hidden secrets. There, too, are those who, in the silence of the laboratory, rejoiced in the fertile marriage of the elements, or they who, like confessors, heard from dead bones or rock or flower

the immeasurable history of the silent ages of earth.

One might linger long over many of these lives whose interests were so remote from thought of the commercial gains their unselfish work made possible. But there are other compensations, and there are men here to-day who are aware that there is no earthly pleasure more supreme than to find disclosed some secret of nature unknown before, save to Him who set in motion the complex mechanism of the universe.

The later life of the merchant and the lawyer loses vitality of normal interest as age comes on; not so the man of science. The eternal love of nature is his—a mistress of unfading charm.

I remember once that, at my table, some one asked that ever happy naturalist, Joseph Leidy, if he were never tired of life. "Tired!" he said, "Not so long as there is an undescribed, intestinal worm, or the riddle of a fossil bone, or a rhizopod new to me."

My first remembrance of an Academy meeting is of 1866. We met in a Smithsonian room. There were not more than fifteen present. Professor Henry was in the chair.

I remember Benjamin Peirce, Wolcott Gibbs and Gould. Agassiz sat on one side of me, and on the other Coffin. It was all very informal. The first scientific paper was by Professor Peirce, who for twenty minutes occupied us with algebraic formulas and mathematical figures, until he turned and said that he had got out of the region of material illustration, and so led us on through the endless equations in which I had lost myself at the very outset.

Agassiz turned to me at the close and said, "Were you able to follow him?" I said, "No; I can not do a sum in the Rule of Three without trying it over two

or three times." Upon which the delighted naturalist added, "*Ni moi non plus.*" Professor Coffin remarked, "He was traveling with Seven-league Boots over a country across which I should have to crawl."

Some of this was quite audible to Peirce, who said that the only thing required was more careful attention than men were willing to give to the great science of mathematics, and that our incapacity to understand and follow him was due to our want of proper education.

He was succeeded by Agassiz, who made the first announcement of his discovery of the additional heart found in the tail of the young of the salmon.

I recall very little else about these delightful people, except that they—all of them—were not only in the peerage of science, but also companions as socially interesting as they were learned.

Perhaps the most pleasant remembrance I have of all is of Louis Agassiz and Joseph Henry. The former was good enough to take a great interest in some of the animal physiology with which I occupied the rare leisure of a hard-worked young doctor. His enthusiasms were shown in odd ways at times.

On one occasion he was staying with Professor Frazier, and dismissed me on the front step one slippery day in February. I had got some distance from him when he came after me in haste, sliding over the pavement. "I did want to say to you one thing. Are you acquainted with the opossum?" I said, rather confused, "No." He said, "I advise you to acquire a physiological friendship with the opossum. He is a mine of physiological wealth."

Jeffries Wyman, who was elected in 1872 and died in 1874, was another who held a place in my most honoring regard. He resembled Joseph Leidy in that splendid magnanimity and unselfishness which con-

trusted so agreeably with the disgusting quarrels, happily rare, which sometimes arose among men of science.

As you have made me speak here, I am forced to say something of myself, and hence this anecdote of Wyman. I had written him word of the discovery I had made of the chiasm of the superior laryngeal nerves in the chelonia—that is to say, turtles—and it greatly excited him, especially my prediction that it would be found in serpents and probably in birds. A year afterwards he sent me a large bundle of illustrations and descriptions of what he had found in other classes than the turtle, and insisted that I should use them in the second paper I was about to print, stating that they would not have been discovered had it not been for my predictive aid. Of course, I declined this help; but it was characteristic of the noblest form of the scientific mind.

You will, I trust, pardon me if I close this long talk with a few too personal words about the much loved first director of the Smithsonian Institution, first of the men who sacrificed to that Institution a scientific career. When a boy about fifteen years old, I was sent by my father to Professor Henry at Princeton with some glass apparatus, which could not otherwise be sent without danger of breakage.

He met me at the station, took me to the house, and spent a part of the next morning endeavoring to explain to my bewildered youth the experiments he was making in the transmission of electric signals. I was overcome by the unwonted attention paid to a boy of my age, and expressed myself so warmly that he laughed as he bade me good bye, saying: "Well, life sometimes gives one a chance to return little favors, and perhaps some day you will have an opportunity to oblige me."

Long years passed by, and some time in

the beginning of 1878 Professor Henry asked me to come to Washington and advise him. After a thorough examination of his case, he asked me plainly if he was mortally ill. I said, "Yes." Then he asked how long he had to live, but I could not set a date. He said, "Six months?" Hardly, I thought. He died in May of that year.

As I arose to go away, his carriage waiting, he said: "I have yet to discharge my material obligation. How much am I in debt to you?" I replied, "You are not in debt. There are no debts for the Dean of American Science."

He was much overcome, and said: "I have always found the world full of kindness to me, and now here it is again." I could only say: "You do not remember, sir, that once you said to me, a boy, when you had been very kindly attentive to me and I tried to express my obligation, that perhaps a time might come when I could oblige you. If this obliges you, my time has come." And so we parted.

I may add what some of you already know, that Alexander Agassiz wrote me he had intended to return home early from Europe, in order to give a dinner such as we are having here to-night. He died on the way over, and his letter reached me after his death—strangely enough, the fourth letter I have received from men who were not alive at the time their words reached me.

My talk has been of men dead long ago, but I should be ungrateful to the longest friendship of my life if I did not pause to remind you of our latest loss in John Shaw Billings. He was a man of too many competencies to allow of even allusive comment here. Few men have been better loved or had so enviable a capacity to convert mere acquaintance into friendship.

It is difficult for a man as old as I am to talk in the gay after-dinner mood, and

if I have been too somber and too personal, I trust that I may not have been guilty of the social crime of having been uninteresting.

#### SCIENTIFIC NOTES AND NEWS

ON the occasion of the installation of the Duke of Northumberland as chancellor of Durham University honorary degrees were conferred on the following men of science: D.C.L., Lord Rayleigh; D.Sc., Sir Archibald Geikie, K.C.B., Sir William Ramsay, K.C.B., Sir T. C. Allbutt, K.C.B., Sir J. A. Ewing, K. C. B., Sir William Crookes, O.M., Sir J. J. Thomson, O.M., and Professor E. B. Poulton.

THE Linnean Society, London, has awarded its Linnean medal to Professor Adolf Engler, of Berlin.

THE French Academy of Moral and Political Science has elected M. Pierre Janet, professor of experimental psychology at the Collège de France, to the chair left vacant by the death of M. Fouillée.

WHEN the Lobachewski Prize was recently awarded to Professor Schur, of Strasburg, the committee also awarded an honorable mention to Professor Julian L. Coolidge, of Harvard University, for his book on "Non-Euclidean Geometry," Oxford, 1909.

THE annual meeting of the Iron and Steel Institute was held in London on May 1 and 2, when the Bessemer gold medal for 1913 was presented to Mr. Adolphe Greiner by the president, Mr. Arthur Cooper. The Andrew Carnegie gold medal for 1912 was presented to Dr. J. Newton Friend.

THE Manchester Literary and Philosophical Society has nominated Sir Thomas H. Holland, F.R.S., to represent it at the twelfth International Congress of Geology, to be held in Toronto in August next.

DR. JAMES W. GLOVER, professor of mathematics and insurance at the University of Michigan, has been appointed expert special agent of the Bureau of the Census to supervise the preparation of a special volume on vital statistics. Extensive mortality tables

are to be prepared, based on the population and vital statistics of the United States. Dr. Glover has also been appointed collaborator to the Office of Public Roads in the Department of Agriculture to assist in the preparation of several bulletins on the various methods of improving and financing public highway bonds.

PROFESSOR AMOS S. HERSHEY, head of the department of political science at Indiana University, and Dean Walter Williams, dean of the school of jurisprudence at the University of Missouri, have been appointed fellows of the Kahn Foundation for the coming year, and both will begin a one-year tour around the world within the month. The fellowships carry with them a stipend of \$3,000 for each appointee and in addition there is an allowance to each of \$300 for purchases.

PROFESSOR HERBERT R. MOODY, of the College of the City of New York, is in residence for the summer term at Oxford University, where he is associated with Mr. T. V. Barker, of the department of mineralogy at the University Museum. Professor Moody is engaged in learning from Mr. Barker the details, so far as developed, of the von Federon method of Crystallo-Analysis. Mr. Barker learned Russian last year in order to work with von Federon in St. Petersburg. The method is not yet made public.

AT the annual general meeting of the Marine Biological Association of the United Kingdom, held in the rooms of the Royal Society on April 30, the following officers and members of council were elected for the year: *President*, Sir Ray Lankester; *Chairman of Council*, Dr. A. E. Shipley; *Hon. Treasurer*, Major J. A. Travers; *Members of Council*, E. T. Browne, L. W. Bryne, Dr. W. T. Calman, Professor H. J. Fleure, Professor F. W. Gamble, Sir Eustace Gurney, Commander Campbell Hepworth, Professor J. P. Hill, E. W. L. Holt, Professor E. W. MacBride, H. G. Maurice, Dr. E. Schuster, G. W. Smith, Professor D'Arcy W. Thompson; *Hon. Secretary*, Dr. E. J. Allen. The following governors are also members of council: G. P. Bidder, the

Earl of Portsmouth, Sir Richard Martin, the Hon. N. C. Rothschild, Professor G. C. Bourne, Dr. A. E. Shipley, Professor W. A. Herdman.

As has already been announced, the committee of the Lister Memorial Fund proposes that the memorial should be of a threefold character: (1) A simple marble medallion bearing a sculptured portrait of Lord Lister to be placed in Westminster Abbey among the monuments of the nation's illustrious dead; (2) a larger and more conspicuous monument to be erected in some public place in London, the city wherein he lived and worked; (3) if funds sufficient shall be obtained, the founding of an International Memorial Fund from which either grants in aid of researches bearing on surgery or rewards in recognition of important contributions to surgical science shall be made, irrespective of nationality. The *British Medical Journal* says that the sum already subscribed or promised is perhaps sufficient for the completion of the first two parts of the proposed memorial, which are of local character, but for the third, or international part of the memorial, an international appeal is now being made, and a letter has been addressed by the secretary, Sir John Rose Bradford, to the principal universities and medical societies on the Continent of Europe and in the United States. A similar letter is being sent to the corresponding institutions in the British dominions and colonies. Among the subscriptions received for the international fund are the following: Academy of Sciences, Paris, 500 francs; University of Paris, 500 francs; Medical Faculty of the University of Montpellier, 250 francs; the Karolinska Medicokirurgiska Institutet, Stockholm, \$5. Vladimir Kowalevsky, president of the Technological Society of Russia, has made a donation of \$5 "in memory of one of the greatest benefactors of the human race." The universities of Michigan, Yale, Harvard and Leland Stanford (California) have already undertaken to promote the memorial, and the College of Physicians, of Philadelphia, has made a special appeal to its fellows. In addition, Dr. Keen, of Philadelphia, is making a somewhat

wider appeal. The University of Toronto has appointed a special committee to promote the fund. The honorary treasurers of the fund are Lord Rothschild and Sir W. Watson Cheyne. The offices of the fund are at the house of the Royal Society, Burlington House, Piccadilly, London, W., and subscriptions, made payable to the fund, may be sent to the treasurers there.

CONGRESS has furnished the Bureau of Entomology with funds to be used in the eradication of the tick which transmits spotted fever in the Bitter Root Valley in Montana. Dr. T. Ricketts demonstrated that the disease is transmitted only by the tick *Dermacentor venustus*. Investigations conducted by the Bureau of Entomology in cooperation with the Montana Agricultural College have shown that a comparatively simple and inexpensive plan of eradication of the tick may be put into operation. Cooperation has been arranged with the Montana State Board of Entomology, recently created at the session of the Montana Legislature, whose duty it is to "study the dissemination by insects of diseases among persons and animals, said investigation having for its purpose the eradication and prevention of such diseases." The board is further required to take steps to eradicate and prevent the spread of diseases that may be transmitted by insects and an appropriation of five thousand dollars a year for the next biennium is made. The immediate object in passing the law was to provide for the eradication of the Rocky Mountain spotted fever tick. The membership of the board is *ex officio* and is made up of the secretary of the State Board of Health, chairman; the state entomologist, secretary; and the state veterinarian.

At the recent meeting of the National Association for the Study and Prevention of Tuberculosis in Washington the following resolutions were adopted: "WHEREAS, Widespread publicity has been given to the claims of an alleged cure for tuberculosis. *Resolved*, That there is no information before the National Association for the Study and Prevention of

Tuberculosis to justify the belief that any specific cure for tuberculosis has been discovered which deserves the confidence of the medical profession or the people, and, *Resolved*, That it is the duty of the public to continue unabated all the present well-tried agencies for the treatment and prevention of tuberculosis."

THE trans-Saharan party of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington arrived at Timbuctoo on May 16. Since leaving Biskra, Algeria, on October 29, 1912, the party has secured complete magnetic observations at about seventy stations.

MR. CAWTHRON, of Nelson, New Zealand, has offered to give \$60,000 for a solar physics observatory.

THE Historical Medical Museum, organized by Mr. Henry S. Wellcome, which is to be opened in London towards the end of June next, will include, as we learn from *Nature*, among the exhibits in the science section a large collection of the original apparatus used by Galvani in making his first experiments in galvanism in the eighteenth century. Other exhibits will be a collection of votive offerings for health, ancient microscopes and optical instruments, amulets and charms connected with English folk medicine, early medical medals and coins from the Græco-Roman period, and early manuscripts and medical books.

THIS week a joint meeting of the Institution of Electrical Engineers of London and the Société Internationale des Electriciens is to be held in Paris.

THE Index of Authors and of Subjects in the first thirty volumes of the *American Journal of Physiology* is ready. The index contains about 160 pages and is bound in paper. The edition is limited. Such indexes are valuable to scholars, even to those who do not possess a file of the *Journal*.

UNIVERSITY OF SOUTHERN CALIFORNIA students have completed the organization of the first Pacific Coast chapter of the Agassiz Association, the national organization of nature

students, choosing Burbank Chapter for their distinctive name. Mr. Luther Burbank will probably be one of the speakers to address the chapter this year. The chapter programs include bi-weekly field trips to points of interest around Los Angeles, frequent social gatherings at the homes of members and monthly lectures by outside naturalists.

THE following lectures have been given during the year at the University of Iowa under the auspices of the department of physics:

"The Ether," Professor K. E. Guthe, of the University of Michigan.

"The Measurement of the Charge of Thermions," Dr. J. C. Pomeroy, of Iowa State College.

Some Physical Aspects of a Comet's Tail," Professor D. W. Morehouse, of Drake University.

"The Elementary Electric Charge" and "An Extension of the Brownian Movement Theory," Professor R. A. Millikan, of the University of Chicago.

"Applications of Least Squares in Physical Research," Professor Leroy D. Weld, of Coe College.

"Carriers of Positive and Negative Electricity," "Properties of the Wehnelt Cathode Rays" and "The Beaded Character of the Cathode Ray Line," Professor C. T. Knipp, of the University of Illinois.

THE subject selected for the Adams prize in 1914 is "The Phenomena of the Disturbed Motion of Fluids, including the Resistances encountered by Bodies moving through them." A theoretical rediscussion of the problem of fluid resistance may be undertaken, either in general or in simple cases, in the light of the experimental knowledge regarding the resistances and the nature of the broken motion of the fluid which is becoming available in the publications of the aeronautical laboratories of various countries. Information has been accumulating regarding the nature and mode of travel of meteorological atmospheric disturbances, such as cyclonic movements and line squalls, the propagation of minute waves of barometric pressure, and the nature of the lower boundary of the upper calm region of the air. A dynamical discussion of these topics, or of simpler problems in illustration of them, might be undertaken. The prize is open to the competition of all persons who

have at any time been admitted to a degree in the University of Cambridge. The value of the prize is about £220. The essays must be sent to the vice-chancellor on or before the last day of December, 1914.

#### UNIVERSITY AND EDUCATIONAL NEWS

In memory of a husband who for years had suffered from a malady that eluded medical skill, Mrs. George William Hooper, of San Francisco, has transferred to the University of California \$1,000,000 for the establishment of an institute of medical research. The foundation is to be controlled by an advisory board of seven members constituted as follows: The president of the Carnegie Foundation, who is now Dr. Pritchett; the professor of pathology at the Johns Hopkins University, the director of the Rockefeller Institute for Medical Research, the president of the University of California, the dean of the Medical School of the University of California, E. D. Connolly, representing Mrs. Hooper, and a seventh member to be chosen by the western members of the advisory board.

THE late Dr. Louis A. Duhring, formerly professor in the University of Pennsylvania, in his will disposes of an estate valued at about \$500,000. His notes on medical cases are given to the university, and the will creates a trust fund of \$25,000, the income of which is to be used for the benefit of the department of cutaneous medicine. The will gives the University of Pennsylvania Hospital \$50,000 for the establishment of free beds in which cutaneous, cancerous and allied diseases shall be treated. After making a number of private bequests, the testator directs that the residue of the estate be given to the trustees of the University of Pennsylvania, and that it be applied to the treatment of cutaneous diseases and their study.

MR. STEVENS HECKSHER has given \$10,000 to the University of Pennsylvania to establish a fellowship in medical research.

FRIENDS of Professor William Otis Crosby have presented to Columbia University the sum of \$1,800 for the establishment of a collection of lantern slides to be known as the

"William Otis Crosby Collection of Geological Lantern Slides."

THE trustees of the University of Illinois have voted that for students entering in September, 1913, the requirements for admission to the College of Medicine (formerly the College of Physicians and Surgeons of Chicago) be raised to at least one year of collegiate work in addition to fifteen units of common and high school work, and that for students entering September, 1914, the minimum requirement further be increased to two years of collegiate work in some college or university of recognized standing.

MR. C. L. DAKE has been appointed assistant professor of geology and mineralogy in the Missouri School of Mines. He was instructor in geology at the University of Wisconsin during 1911-12, and during 1912-13 at Williams College.

DR. LEO F. GUTTMANN, formerly head of the division of physical chemistry at the College of the City of New York, and for the last four years assistant professor of physical and industrial chemistry at Queen's University, Kingston, has been appointed associate professor of chemical engineering.

DR. GEORGE SHANNON FORBES, instructor in Harvard University, has been promoted to be assistant professor of chemistry.

PROFESSOR OSWALD KÜLPE succeeds Professor Th. Lipps as professor of philosophy at Munich.

#### DISCUSSION AND CORRESPONDENCE

##### THE LAWS OF NOMENCLATURE IN PALEONTOLOGY

TO THE EDITOR OF SCIENCE: A number of recent letters in SCIENCE on the subject of nomenclature may serve as an excuse to present to those interested a few of the special difficulties that beset the vertebrate paleontologist in questions of nomenclature.

The writer holds no brief for the law of priority. Names, scientific or popular, are, after all, but words designed to convey a certain concept, and the fixity and uniformity of that concept might quite well have been—or be—secured by an official dictionary which

should do for scientific names what the standard dictionaries do for words in general, namely, embody and fix as accurately as possible the current usage and significance of the word. That is what the proposal for an official list of scientific names amounts to, if carried out to the limit of its apparent trend. It would no doubt substitute references to types or descriptions for the dictionary definitions of meanings; but that is unessential.

The real objections to such a plan, as it seems to me, are (1) that the law of priority is so thoroughly imbedded in the mind of most systematists, and regarded so much as a moral or legal issue, a matter of justice to the first describer or of correct interpretation of certain statutory rules, rather than as a matter of convenience, that the authorities in systematic work would not abide by dictionary usage in the matter. (2) That any extensive list that could be prepared would certainly contain many names that were open to exception because the references or types so standardized were inadequate, or the current usage not approximately universal.

The first objection is illustrated by Dr. Dall's contemptuous rejection of the proposition that proposals approved by the majority of the committee on nomenclature should be submitted for endorsement or rejection to the body of the Zoological Congress. He will not abide by majority rule in the matter, even a majority of a committee of experts; and for a majority decision of "five dollar subscribers" he has no respect at all. The second objection is one that would be of special weight in any attempt to standardize the nomenclature of vertebrate paleontology.

But it has been said: If the systematists will not conform, let them go their way, and the rest of us go ours. To such a remark one can only say: Try to put such a scheme in the form of a definite program and see where it would land you. The scientific body is an organic whole interacting in all its parts, and *Æsop's* fable of the belly and the members is very much apropos. Altogether it would seem that the present methods and usages, annoying and exasperating as they often are to the

teacher and morphologist, wasteful and time-consuming to the systematist, can not be modified to any material extent without causing further confusion.

The systematists are in the habit of assuring us that this confusion is only temporary; that when the laws of priority have been correctly and exactly applied to all species and genera, a stable and unchanging nomenclature will result; there will be no further changes. So far as vertebrate paleontology is concerned, I am certain that this optimism is unjustified and I doubt whether it is so in other branches of zoology. After the nomenclature has been revised it will be stable until somebody revises it again, just so long and no longer. Every new reviser, having new evidence at hand, or stressing differently the data already considered, is liable to interpret the case differently, and each difference in the interpretation of some obscure or minor point is liable to result in a whole series of alterations of well-known and important names. Only by forbidding the re-investigation of cases already authoritatively considered can changes be prevented. And that is just what Professor Ward's committee wants to do, and Dr. Dall makes it clear that systematists of the highest standing would not accept any such ruling. The plain fact of the case is that scientific nomenclature has come to a pass where the common name of a species is the only name with any permanency or prospects of permanency, and it is necessary to use it or to provide one if there is none already, in order that one's readers—aye, even other systematists—shall know what animal is under discussion. A century ago scientific writers wrote descriptions in dog-latin and then explained in good English or other modern languages what they were talking about. To-day they write descriptions under a scientific name dug out of some old forgotten treatise, and provide it with a wealth of learned synonymy, and then explain by means of the "dear old familiar name of the text-books" or the still dearer vernacular name, what animal it is that they are describing. Fashions change; not always in the way of progress.

In his last letter, Dr. Dall suggests a method of reconciling the differences between teachers and systematists by allowing the use of the "text-book name" with the status of a vernacular name, and a plus sign before it. I adopted a somewhat similar compromise some years ago, in a check list of American Tertiary mammals, only I put the commonly accepted name first, and the "correct" name afterwards, enclosed in brackets and with an equality sign before it. Now doubtless there are specific differences between this and Dr. Dall's discovery, but I claim that the *genus* is the same, and that therefore, I am entitled according to the law of priority of which he is so able a defender, to that statue which he expects to receive from the grateful teachers. Especially as I am sure my modification would be more acceptable to them, and while I feel less certain of his cordial approval, I don't see what legitimate exception he can take to it.

The vertebrate paleontologist is in some respects almost free from the difficulties in interpreting and applying the laws of nomenclature that beset his zoological brother. The literature with which he deals is mostly of recent date, and reasonably cognizant of the laws and decencies of nomenclature. There are only a few cases in vertebrate paleontology where there is any particular difficulty in fixing the type of a genus, the date of its publication or the species intended to be included under it.

His serious problem lies in the nomenclature of species, the identification of type specimens, and especially to know what to do with the fragmentary and almost indeterminate types of most of the older and many of the newer species, in relation to more complete specimens subsequently obtained. A quotation from Professor Marsh may be apropos.

A single tooth or vertebra may be the first specimen brought to light in a new region and thus become the sole representative of a supposed new form. The next explorer may find more perfect fragments of the same or similar forms, and add new names to the category. A third investigator with better opportunities and more knowledge may perhaps secure entire skulls or even

skeletons from the same horizon, and thus lay a sure foundation for a knowledge of the fauna.<sup>1</sup>

The wording is curiously suggestive of Professor Marsh's probable opinion of the activities of Leidy, Cope and himself in the field of American paleontology; but it is at all events a sufficiently accurate description of the general progress of the science. The earliest finds in any newly explored formation are generally fragments. They are new, they are of scientific importance, they are distinct from forms hitherto known, they ought to be described and figured, and they ought to be named as a matter of convenience in scientific discussion. But they will undoubtedly make trouble later for the systematist. The "next explorer" must either "add new names to the category" or identify one or more of his fragments with the first described type. And if his material comes from a different locality such identifications may cause serious errors in stratigraphic correlation. The third investigator may ignore the earlier types as too incomplete for identification, or he may arbitrarily identify them with such of the species secured by him as suits his convenience. Either method will subject him to criticism and be liable to mar the scientific results of his investigations.

It is a covenant universally accepted that a new species is not to be described unless it can be shown or inferred to be different from all previously described species. But here it simply can not be applied. The third investigator may have at hand skulls and skeletons of a dozen species all clearly distinct from one another, yet any one of them may be conspecific with the tooth or fragment on which an earlier species was founded, and it is often absolutely impossible to find in the type any characters that are really valid evidence for referring to it one rather than another of these later discovered species.

The difficulty in treating of these more or less indeterminate species recurs again and again in the literature of vertebrate paleontology, causing endless confusion and error when arbitrary identifications are subsequently

<sup>1</sup>"The Value of Type Specimens," *Am. Jour. Sci.*, 1898, Vol. VI., p. 402.

found erroneous and infinite recrimination and heartburning when the work of earlier authors is set aside or ignored. These troubles we shall have with us always; but perhaps their amount might be reduced if an intermediate course were adopted.

The earlier type may be a specimen showing unmistakable ordinal, family or generic characters, but not adequate as a specific type. Let it stand so. Do not set it aside as "indeterminate," but specify the extent to which it is determinable. It can remain in the literature and be included if desirable in faunal lists, but additional material should not be referred to it unless the new specimens be topotypes, *i. e.*, from the same locality and the same geological level, so far as these are recorded or can be safely inferred from the literature, unpublished notes or labels or the appearance of the specimen. If it has valid generic characters a genus founded upon it is valid, and other species may be referred to it; if it has family characters but no distinctive generic characters, a family name founded on the genus is valid, but no subsequent genera are to be synonymized with it except when species of those genera are known to occur in the locality and geological horizon of the older genotype species. In illustration a few cases may be cited:

1. *Anchippodus riparius* Leidy 1868, type a lower molar from the "Miocene" (? Oligocene) of New Jersey. Type of the family Anchippodontidae Gill 1872, referred to the order Tillodontia Marsh 1875. Leidy referred to this genus and species in 1873, his *Trogosus castoridens* 1871 based on a lower jaw from the Middle Eocene (Bridger formation) of Wyoming and to the same genus Marsh's *Palaeosyops minor* 1871, based on a lower molar. Marsh, subsequently obtaining complete skulls and skeletons of related animals, accepted Leidy's genus *Anchippodus*, described a new genus *Tillotherium* with three new species, and based upon it the family Tillotheridae which he made typical of the order Tillodontia.

No topotypes of *Anchippodus riparius* are known. Subsequent authors have either fol-

lowed Marsh in ignoring Gill's name, while accepting Leidy's identification of *Anchippodus* with *Trogosus*, and considering *Tillotherium* as distinct from the latter, or they have used Anchippodontidae as the family name, while deriving all the characters of the group from Bridger materials.

The result is that the faunal lists record in the New Jersey "Miocene" along with a known Oligocene mammalian fauna (*Cænopus*, *Entelodon*, *Protapirus*) a genus and species of the Middle Eocene fauna, while the western collections make it reasonably certain that in those regions the family and order disappeared with the Middle Eocene. Were this conclusion supported by real evidence, it would lead to some interesting corollaries as to migration and survival. In fact it is quite misleading. The type of *Anchippodus riparius* is inadequate for specific or generic comparison, and doubtfully adequate for family or ordinal comparison. It is very improbable that it is congeneric with *Trogosus*, hardly possible that it is co-specific with *T. castoridens*, so far as one may judge from the associated fauna in absence of generic or specific characters in the type specimen. Gill's family characters were drawn from *Trogosus*, and since it is doubtful whether this genus belongs in the same family with *Anchippodus*, his family should be held as doubtfully synonymous with Tillotheriidae, both names to be retained, but the former as " ?Anchippodontidae Gill, fam. indet."

2. *Hippodon* Leidy is the first genus of three-toed horses described from this country. The type is *H. speciosus*, based upon a lower molar tooth. Leidy subsequently referred to the species upper teeth, etc., which he considered congeneric with the older European genus *Hipparion*. On the basis of these and other referred specimens the species was held valid and the genus a synonym of *Hipparion* until Gidley revised the three-toed horses in 1907. No topotypes were or are known. Gidley set aside both genus and species as indeterminate. I subsequently identified and located the type specimen which had been missing, and after making a fairly careful com-

parison came to the conclusion that it was a species of *Merychippus*. A more thorough restudy of the Miocene horses last summer brought me to the conclusion that this tooth, while certainly distinct from *Hipparion*, lies somewhere near the border line between *Merychippus* and *Protohippus*; but on which side of the line I can not determine except arbitrarily. The species is, therefore, in fact indeterminate generically, and a valid genus can not be based upon it. *Hippodon* would, however, stand as the type of a group including *Merychippus*, *Protohippus* and *Pliohippus* as contrasted with *Hipparion* and *Neohipparion*. In stratigraphic correlation of the beds at Bijou Hill, where it was found, it would be listed under the *Protohippinae* as *Hippodon speciosus* gen. et sp. indet.

3. *Deinodon* Leidy is determinable as to family, but is not determinable generically, as the genera of carnivorous dinosaurs are now distinguished. The same is true of a whole series of genera and species described by Leidy and Cope from the Judith River. The treatment of types and referred specimens of these genera by paleontologists as specifically distinguishable or identical has sadly misled Dr. Peale in his recent discussion of the vertebrate evidence as to the age of the Judith River beds, leading him to present as conclusive evidence of identity in age a correspondence in fauna which to those who know the nature of the specimens on which the lists are based is no evidence at all.

In brief the plea is for the full recognition of nomenclature laws, but for the avoidance of arbitrary or unprovable identifications in the future, and the recognition of the actual facts as to the extent to which described genera and species are truly determinable. The allowed exception in the case of topotypes is based upon an inference of identity which it would seem impossible ever to prove incorrect. In all other cases the chances that future discovery may upset an arbitrary identification should prevent its being used as a basis for changes in nomenclature.

The source of the present lamentable situation in nomenclature is that an excellent sys-

tem of procedure, designed to settle unsettled questions, has been wrenched from its intent and used to unsettle settled questions. The present writer, having studied with more or less care the majority of the type specimens of American fossil mammals and reptiles, has abundant evidence at his command to upset by a strict application of the accepted laws and procedures, much of the present nomenclature, including many of the alterations proposed in recent years upon grounds of priority. But he has no intention of so misusing his opportunities, or of being responsible for such changes until convinced that they will really result in greater stability.

W. D. MATTHEW

#### HOW IS THE WORD FOOD TO BE DEFINED?

THE query expressed in the title "How is the word 'food' to be defined?" is suggested by a restrictive usage of this word which is rather prevalent in American text-books of elementary botany, and which seems to have originated among American plant physiologists. Presumably it had its birth in university courses in botany where the arguments for its use were given and understood, but as it appears in the elementary texts, it involves a marked inconsistency of thought and expression for which no provision is made. Since it represents a striking divergence from the ordinary meaning of the term "food," it deserves wider consideration, looking either toward its general adoption, if desirable, or else toward its discontinuance.

The word food, according to its ordinary connotation, is applied to any substance which, when taken into the body of an organism, can be used by that organism in the construction of new tissue. Definitions of essentially this content are to be found in the Century, Standard and Webster dictionaries. Using this definition as a basis, we should consider as food for green plants the water, carbon dioxide and mineral salts absorbed from the surroundings. According, however, to the restricted usage, these are not considered as "foods," but are referred to as "raw materials," "nutrients," "food materials," or some other cir-

cumlocation. Bergen and Davis<sup>1</sup> have a sentence which shows clearly how the restricted usage conflicts with the general usage illustrated by the definition given above:

The series of processes by which the plant (1) takes in *raw material* to form its *foods*, (2) unites these into *foods*, and finally (3) constructs tissue from these *foods* or (4) stores them, constitutes nutrition.

Gager in a recent book-review<sup>2</sup> has given another excellent illustration of the same conflict of usages in the sentence which follows:

On page 38, mineral *nutrients* are erroneously called plant *food*. [The italics of both quotations are mine.]

Judging from these quotations, it is evident that the content of the newer usage is entirely different from the older general usage. Carbon dioxide, water and mineral salts, all clearly to be classed as plant food under the older definitions, can not be so classed according to the newer usage. By a process of exclusion, after a consideration of the quotations just given, we arrive at the following new definition of the word food, viz., *organic materials available for immediate assimilation*. It appears, however, from other discussions that the intentions of the proponents is to apply the term food also to the organic raw material used by animals or colorless plants.

Two questions arise from the foregoing consideration: (1) Why has the new meaning of "food" arisen? (2) Does it deserve to prevail?

The arguments for the restricted usage are derived mainly from a comparison of the nutrition of green plants with that of animals. The food of an animal is chemically practically the same material as the tissues of the animal and consists of proteins, oils, fats and carbohydrates. (Mineral matter may be excluded from the consideration for the present.) During the process of digestion, this food is temporarily simplified as far as may be necessary to make it soluble. Assimilation

consists merely in the reconstruction of compounds in general like those found in the original food. In the case of green plants, all the materials obtained from the surroundings are simple inorganic substances. The process of preparing them for assimilation is a complex synthesis, carried on by means of energy derived from an external source. At the end of this process we find ready for assimilation substances of the same sort as those which result from animal digestion. The ensuing process of assimilation is the same in green plants as in animals. These differences and similarities in materials and processes form the basis for the revised definition of the word food.

The reasons for adopting the new definition have been discussed in detail by Barnes.<sup>3</sup> They may be briefly recapitulated as follows: Protoplasm, being the same in green plants as in animals and colorless plants, and the material which it can actually assimilate being always organic, it creates an undesirable antithesis in thought to recognize as food for living things both inorganic and organic substances. Carbon dioxide and water if recognized as food for green plants can be so considered only for the chlorophyll-bearing cells, and for these only in the presence of light. They can not be used as food by the chlorophyll-less cells at any time, or for green cells in the absence of light.

Notwithstanding the weight and authority of the arguments in favor of restricting the meaning of the word food, there are numerous objections which should be given consideration.

One of the principal objections to be noted arises from the fact that the difficulty noted by Barnes and others is mainly of academic interest. So far as I have been able to discover, the question has been discussed only in two treatises of plant physiology designed for use by university students (Barnes and Green). Apparently, then, to be thoroughly conversant with the new usage, it is necessary

<sup>1</sup>"Principles of Botany," p. 106, 1906.

<sup>2</sup>Payne's "Manual of Experimental Botany," *Torrey*, 12: 134.

<sup>3</sup>Coulter, Barnes and Cowles, "Physiology," 3: 356-8.

to have used one of these texts or to have pursued an equivalent course in plant physiology.

Correlated with the objection just noted is another concerned mainly with the teaching of the restricted usage in courses in elementary botany in secondary schools. The clearest approach in beginning a course in botany in a high school lies in leading the pupil to think of plants as separate living things, each of which is an individual, which has, like an animal, its problems of food getting, nourishment, protection, etc. The university concept of the word food, however, requires that the pupil think of a green plant as an aggregate of different kinds of cells which bears a very different relation to its surroundings as regards its food than the living things, *i. e.*, animals, with which the pupil is familiar. The pupil thus loses the definiteness of the idea of a green plant as an individual with problems like those of animals, and has to think of it as something which does not get its food from without, but must manufacture it within its cells. The phraseology of this usage of the word food has been written into the elementary texts without, so far as I have been able to find, any attempt to make the pupil understand how or why it differs from the older usage. As a consequence he learns to use the word food, in the class at least, in a very different way from his ordinary understanding of it, but usually without any realization of the inconsistency.

Complications follow the restriction in meaning which do not appear to have been realized. In the case of green plants food, in the restricted sense, includes only organic material prepared within the cells of the plant and available for assimilation by any of the cells. In the case of animals, food is first, the organic material which, if taken into the alimentary tract, is able to be digested, and second, the material resulting from such digestion, even yet extra-cellular, but comparable with the material recognized as "food" of green plants. Thus it appears that future dictionaries will need to give at least two definitions of the word food.

If we accept the modified definition of food

as desirable, we shall then have to face the task of making it part of the common knowledge of all who use the English language. Under present conditions it is practicable to teach it only to the minute proportion who pursue courses in plant physiology in colleges.

Referring to the antithesis in thought to which Barnes objected, it may be noted that this has apparently given little or no trouble to a number of well-known botanists who have discussed plant nutrition in text-books. It appears to have occasioned no difficulty in the elementary texts of Atkinson and McDougal; in the general texts of Bessey, Sachs, Strasburger, etc.; in the physiological treatise of Jost. Ganong in his text-book of physiology refers to the restricted meaning as desirable but as probably impossible to promulgate.

It seems to the writer as entirely unnecessary to attempt to make so great a distinction between the food material of the individual green plant as a whole and the food material of its constituent cells, or between the crude food materials of green plants and animals. It is possible sufficiently to differentiate the materials and their processes of preparation without revising out of conscience the ordinary meaning of an old and useful word. It would appear sufficient to satisfy all the needs of discrimination to use expressions like "crude food" and "cell food." [Since the preceding sentence was written, practically the usage suggested there has been used in high school classes with good results. The use of the expression "cell food" emphasizes to pupils the idea of the cells as the unit of structure and function in living things.]

Finally it may be noted that in the last analysis, it is strictly impossible to restrict the word food wholly to organic material. Barnes limited his discussion of the question to carbon dioxide and water and the carbon compounds resulting therefrom. He expressly excludes mineral salts from his consideration as too small in amount to deserve attention. Logically, however, they can not be excluded even on this basis and especially not in view of the fact that the nitrogen, sulphur and phosphorus of protoplasm are derived from

mineral matter. Moreover, although it is relatively easy to distinguish between  $\text{CO}_2$  and  $\text{H}_2\text{O}$  on the one hand as inorganic "food materials," and sugars, starches, etc., on the other hand as manufactured "foods," who can say when nitrogen, sulphur and phosphorus cease to be "food materials" and become "foods"? Is it not more than probable, also, that some constituents of the mineral material taken in by plants and animals are immediately available for assimilation in the form absorbed, and are thus foods in both the restricted and broader senses of the word? If the facts are as here suggested, it is clearly impossible to limit the term food to organic material, first because too little is known of the metabolic processes by which nitrogen, sulphur, phosphorus, et al., are assimilated to enable any one to say at what stage these elements cease to be parts of inorganic and become parts of organic compounds, and second, because some inorganic substances are probably *foods* in both senses of the word.

In conclusion, the question asked in the title may be repeated. How is the word food to be defined? Is it to be limited to organic substances with all the pedagogic and scientific difficulties which such limitation entails? Or shall it remain as at present, raising no practical difficulties whatever and leaving the academic difficulties involved to be dealt with when the pupil becomes sufficiently mature to understand them?

#### A STANDARD FORM OF COMMITTEE MEETINGS

DISTANCES in the United States are so great that it is often impossible for a committee to hold a meeting, and its work must be done by correspondence. Owing to the international, or national, character of many committees, and the increasing amount of friendly cooperation among scientific men, some standard system of arriving at results is greatly needed. It would then only be necessary when appointing a committee to state that its work would be done in this way, and the chairman would be saved the necessity of devising a method in

each case, and the doubt in many cases, whether he was justified in appending the names of all members to his report.

The following method is accordingly suggested: The chairman or secretary should have three letters manifolded, and sent in due course to each member of the committee. The first of these should state the exact terms of the appointment; the objects desired; a request for suggestions for the report; an opinion whether a meeting is advisable, and if so, when and where.

The second letter should contain a preliminary report embodying the suggestions received, and in cases of doubt asking numbered questions to which, if possible, the answer will be yes, doubtful, disapprove, or no. In the first three cases, the writer accepts the views of the majority of the committee. In all four cases, he authorizes his name to be attached to the report, provided that it contains a statement that he dissents from the questions to which his reply is no. Prompt answers are requested, but if any member fails to reply after a letter has been in his hands for a week, the chairman may assume that he assents.

The third letter should contain the proposed report, to which all the names would be attached unless answers were received expressing dissent. Some of the members might prefer to make a minority report. If no reply was received to letters one and two, letter three should be registered with a request for a receipt, as otherwise the previous letters might not have been received. If haste is important, night letters are generally to be preferred to telegrams, since the delay from the most distant points of the country would seldom exceed twenty-four hours. If a reply by cable is necessary, the chairman should give his cable address, and if possible arrange all his questions so that each answer shall consist of only one or two words. A reply by cable, in which the fifth question related to a place of meeting, might read: Fieldsmith, Washington. One, two, yes; three, no; four, doubtful; five, London, July. Brown.

## QUOTATIONS

## UNIVERSITY LIFE IN KANSAS

THE vague feeling of unrest that has prevailed among the members of the university faculty on account of sweeping changes that might be made by the new board of administration has deepened into real alarm with the announcement from the board that all positions at the university have been declared open.

This is understood to mean that when the new board takes charge formally July 1, the entire faculty must be reengaged. The fact that a member has been elected a permanent member of the faculty by the board of regents in previous years after serving an apprentice term of years would not necessarily count at all with the new board. The board has by its announcement indicated that it will feel free to drop any member of the faculty it pleases.

That such will be the attitude of the new board is indicated by its action at a meeting last week when Chancellor Strong and President Waters were "reelected" to the positions they now occupy. As there was no definite limit to their "terms" it is hard to explain the action of the board other than by the supposition that it is its intention to wipe the slate clean and build the university anew "from the ground up." If any person has a position on the faculty after July 1, he will hold it directly from the new board of administration and not by virtue of the fact that he has grown old in the service of the institution.

Naturally, this plan of procedure has made the faculty very uneasy. It has been customary to reelect a new member for a number of years, until he had proved his worth to the institution, and then the regents would elect him a "permanent member" of the faculty. Under the new rule the old members are placed in the same boat with instructors of a single year's standing. None of them will know until after the "election" whether they are to be turned on the faculty. It is not an uncommon thing for a professor to have enemies. How is he to know that his enemies may not have the ear of the board, spreading little stories that reflect upon him? The old

board of regents made it a practise to pay very little attention to such stories, although they heard plenty of them. But what the new board will do is entirely a matter of conjecture.

The most envied members of the faculty at the present time are those who have had offers of situations elsewhere. Of course everything may turn out all right, but, on the other hand, men who otherwise would have nothing to be alarmed at may be eliminated when the new broom begins to give its exhibition of clean sweeping. And a good many teachers have remarked privately in the last few months that they intended to take the first fair offer from elsewhere that presented itself. The talk about abolishing and consolidating and transferring courses was enough to make them uneasy, but the announcement now made that every teacher is likely to be treated as if he were for the first time an applicant for a position at the university has caused a decided feeling of insecurity.—*Lawrence Gazette.*

## SCIENTIFIC BOOKS

*A History of European Thought in the Nineteenth Century.* By JOHN THEODORE MERZ. Vol. III. (Part II., Philosophical Thought). New York, Charles Scribner's Sons. 1912. Pp. xiii + 646.

Nothing so well illustrates the profound interest of the great subject undertaken by Dr. Merz as the contrast between his work and Whewell's "History of the Inductive Sciences" (3d ed., New York, 1858). The evident superiority of the later history, especially in intensive treatment and exact *Facharbeit*, is in itself an index of the wonderful progress that characterized the nineteenth century, notably after "The Origin of Species." Fortunately, too, Dr. Merz has been content to take time. His first volume was published in 1896 (3d ed., 1907), and in it he grappled with the physical sciences. The second volume followed at an interval of seven years, and completed the task, as concerned the "sciences of nature." These volumes should be in the hands of every builder of "natural knowledge." It is to be hoped that the appearance of the

volume now before us will lend new stimulus to the sale of its predecessors. A fourth and concluding volume is yet to follow. But we have evidence, and to spare, that, once more, an Englishman of business affairs has arisen to occupy a place alongside George Grote and many others (Darwin not least) who, without academic support or connections, have accomplished so much for the advancement of British science, and the preservation of its distinctive temperament. As it stands, "A History of European Thought in the Nineteenth Century" is a magnificent performance. To the patient thoroughness of the German, Dr. Merz has added the clearness and, in the best meaning, the common-sense of his own countrymen. He carries his load without the aid of any partisan theory, he has no pet ideas to exploit. And although, the very nature of the case preventing, I am not yet convinced that his discussion of philosophical thought is as successful as his presentation of scientific achievement, nevertheless it is plain that Part II. bids fair to be as invaluable as Part I.

The volume contains six chapters: Introductory; On the Growth and Diffusion of the Critical Spirit; Of the Soul; Of Knowledge; Of Reality; and Of Nature. The plan demands some elucidation. Dr. Merz points out that "In the beginning of the century, both in Germany and England, science and scientific thought played only a secondary part in literature and teaching. France was the only country in which it had early acquired that position and commanded that esteem which it now enjoys everywhere" (p. 91). The nineteenth century brought about a change which "amounts in many cases to a complete reversal of the estimation in which the mathematical and natural sciences, on the one hand, the historical and philosophical, on the other, are held. The earlier part of this history has furnished the answer to the first half of the problem: I there endeavored to show that the success and assurance of scientific thought has grown with the growth and diffusion of the scientific spirit, which has been more clearly defined as the exact or mathematical spirit. . . . The second part of this history will have

to answer the other half of the above question, namely, what are the causes that have brought about that great change in the general and popular appreciation of philosophical discussions? How is it that instead of one or two dominant systems of thought we have now what may be called a complete anarchy, or, at best, a bewildering eclecticism? . . . I will at once answer this question. The great change referred to is owing to the growth and diffusion of the critical spirit, taking this term in its widest sense" (pp. 93-95). Accordingly, the scene being thus shifted, there is no little need of the warning that Dr. Merz is careful to issue. "I think it will be more helpful to my readers if, when entering on a new portion of my subject, I immediately impress upon them the necessity of adopting an entirely different point of view from that to which they may have become accustomed by the perusal of the former volumes. So strongly do I feel the necessity of this, that I am inclined to say that, except they are prepared to familiarize themselves with an entirely altered set of interests, problems and methods, I shall fail to gain, or to retain, their attention in that which follows" (p. 34). This, then, indicates the general setting.

The method employed to reach the special divisions is also set forth clearly. "The dualism which pervades all modern thought will occupy us quite as much as the attempts towards unification" (p. 56). "In Leibniz philosophical thought arrived at the position which, with certain interruptions, it still occupies at the present day; its task being, not to afford new knowledge, but to mediate between the claims of two kinds of knowledge: that which deals with things surrounding us in time and space, and that which deals with the highest questions of our life, our destiny, and our duties" (pp. 334-335). Thus, following Kant's famous pronouncement, at the close of the "Critique of Practical Reason," Dr. Merz finds himself confronted with two central problems. "The first begins with the place which I occupy in the outer world of the senses and expands the connections in which I stand into the invisibly great, with worlds upon worlds

and systems upon systems, moreover, into limitless ages of their periodic motion, its origin and duration. The second begins with my invisible Self, my personality, and represents me as standing in a world which has true Infinity, but is accessible only to Reason." Each of these problems, in turn, splits into several parts. Therefore, Dr. Merz proclaims: "I am not primarily interested in expounding the different philosophical systems, but rather in tracing the leading ideas which have survived these systems themselves and become the common property of the philosophical mind at the present day. . . . As we saw that the scientific activity of the century resulted in the firm establishment of a small number of leading conceptions, so I shall now endeavor to show how the huge and frequently conflicting philosophical literature has left behind it a small body of guiding ideas which form the enduring bequest of nineteenth-century speculation" (pp. 39-41). Hence, "looking at the different national interests which promoted philosophical thought in the three countries [*i. e.*, England, Germany and France], we are led to a first division of this great subject which is given by the terms psychological, metaphysical and positive" (pp. 45-46). Besides this, there is the sphere of individual beliefs and convictions which "have quite as much the right to be regarded as facts as any more definite, scientific or historical knowledge" (p. 53). The latter are to be treated in Vol. IV., and again in six chapters: Of the Beautiful; Of the Good; Of the Spirit; Of Society; Of Systems of Philosophy; and "will close with a summary of the general outcome of Philosophical Thought during the Nineteenth Century" (p. vi). Of the former, now before us, but one seems to call for further comment, the rest are self-explanatory. In these days, what does Dr. Merz mean by "Of the Soul"? He answers: "I have headed this first chapter which deals with a definite philosophical problem: 'Of the Soul.' I might have chosen several other words which would have equally introduced us into that portion of philosophical literature with which I am now concerned. . . . That I nevertheless pre-

fer to speak of the soul and not of the human mind or human nature, may be justified by the fact that the word soul introduces us at once to a historical discussion which took place in the middle of the century in Germany, and which may be considered to mark one of the great changes that have come over our way of regarding all questions connected with the mental life. What was called at the time 'Die Seelenfrage' occupied the foremost place in philosophical discussions carried on both by philosophers and naturalists. . . . It seems appropriate to start the history of philosophical thought with an account of the problems which center in the word soul" (pp. 196-199).

Thanks to limits of space and to the fact that technical criticism of philosophy is out of place here, I must content myself with a few summary remarks about the contents of the book. The introductory chapter offers an admirable review of the temperamental differences between science and philosophy, and of the conditions that governed reflective thought throughout last century; while the chapter on the critical spirit is the best synopsis of the historical sciences within my knowledge. Seeing that the scientific and critical movements are the twin intellectual achievements of modern thought, and that the one can not be understood apart from the other, this distilled statement should prove most illuminating to all workers in the physical and biological fields.

Turning to the philosophical chapters, the point of view may be hinted. It is sufficient to say, perhaps, that Dr. Merz deems Lotze the most typical and discriminating thinker of the age. Consequently, he tends to pivot German thought upon the Göttingen professor and, as a sequel, to lay much stress upon Renouvier for French and Professor James Ward for English philosophy. Seeing that Renouvier has not dominated French thought at any time, and that Dr. Ward has never wielded such influence in Britain as Green, the Cairds, Wallace and Bradley, this view seems difficult to maintain. Despite Lotze's failure to found a "school" in Germany, Dr.

Merz's contention may be justified from a purely historical standpoint, although, even here, I have grave doubts (*cf.* pp. 266 f.). For, the clear statement of Lotze's position (pp. 501 f.) amounts to a fatal criticism philosophically! The single proposition—"relations which endure and events that happen, imply things in and between which they subsist" (p. 502)—is in itself sufficient condemnation. Another interesting feature, interesting especially to scientific men, is the rehabilitation of Schelling (pp. 453 f.), who, we are told, "deserves to be looked upon as the central figure during the idealistic period of German philosophy" (p. 453). Now, although Dr. Merz seems to me to begrudge the immense influence of Hegel, he is bold enough to affirm that "Hegel deserves to be looked upon as the greatest representative of philosophical thought in the nineteenth century" (p. 476). Of this there can be no question, I think. But how this conclusion, which Hegel literally wrings, as it were, from Dr. Merz, is to be reconciled with the primacy accorded to Schelling is hard to understand. Nevertheless, the appreciation of Schelling, and particularly the effort to remove the misconception that has been heaped upon him, was greatly in need. Omitting many other notable matters, I would simply record that the chapter on knowledge is, in my judgment, the most successful; while the discussion of the problem of nature is the most suggestive, so much so, that it can not fail to appeal to followers of the natural sciences. Dr. Merz handles the vast wealth of material with astonishing skill, intimacy and perspicuity.

As was inevitable in work done on so large a scale, there are some few unguarded statements. I can not but think that the tendency to separate sharply between "outer" and "inner" results in a false contrast (p. 12). It would be much nearer the truth to say of D. F. Strauss, that the issues he raised were misunderstood by his own contemporaries, than that "the conclusions he came to were premature" (p. 169). It is doubtful, if no more, whether any such relation between Hume and Kant as is put forward for fact

(p. 229) could be proven historically. The remark about psychology (p. 252) is scarcely in focus. For, even granted that the old psychology disappeared, we had ample compensation in *Völkerpsychologie* and *Sprachwissenschaft*, both traceable to the very movement which Dr. Merz tends to condemn. Indeed, the main defect of the "History" is to be found precisely in its prevalent tendency to minimize this same movement. There is an astonishing misconception of Fichte's problem (p. 234), and a curious comment about Spencer's knowledge of Kant (p. 296), whom, as Spencer himself informs us, he could not read. It ought to be noted, finally, that the scope of the work is not European. Dr. Merz really confines himself to the three leading nations—France, Britain and Germany. The omission of Italy, particularly after the work accomplished by her when her political unification was won, is to be regretted. But, we should not look a gift horse in the mouth. These are mere blemishes, never blots, on a very remarkable achievement.

The publishers (Blackwoods, Edinburgh) ought to have their share of commendation. Considering the size of the volume, and the elaborate notes with which it literally swarms, the press work is exceptionally free from errors. A letter dropped in the marginal summary (p. 12); J. F. for J. H. Tufts (p. 57 n.); J. M. for T. M. Lindsay (p. 209 n.); Taylor for Tayler (p. 306 n.); Eucken's work (p. 436 n.) is not a "little tract"; Thompson for Thomson (p. 612 n.)—an insignificant total. The index is excellent—a most important consideration in so voluminous a performance. Dr. Merz promises that, "when the fourth volume appears," it "will be cancelled to make place for a more comprehensive index covering both volumes" (p. vi). In these circumstances, I venture to append a list of errors for correction then. Under De Morgan, "Study of . . . Metaphysics, 576" should read Study of . . . Mathematics, 376; "McCormick" should read McCormack; there is a reference (p. 165 n.) omitted under "Lexis." "Ravaisson-Mollien" is misleading. Ravaisson did adopt the name of his maternal

uncle, but not till after his classical "Rapport" (of 1867, not 1868, as on pp. 201, 234, 426); quite rightly, he is always referred to in the text by his paternal name, without the later addition, and should be so noted in the index. Under "Schiller" philosophy has been substituted for history. "Ænesidemus" is correctly printed under "Schulze, G. E.," incorrectly on p. i of the index. Under "Ueberweg," T. M. should be substituted for J. M. Lindsay; and "Taylor" should read Tayler. The caption "Cause and effect defined" should be thoroughly revised and extended. There are several references in the text of far greater importance than the single one recorded in the index.

R. M. WENLEY

ANN ARBOR

*Electrical Machine Design.* By ALEXANDER GRAY. McGraw Hill Book Company.

"Electrical Machine Design," by Alexander Gray, discusses the theory of operation and design of direct current generators and motors of both interpole and non-interpole type, alternating current generators, induction motors and transformers. Five hundred and seven pages are not enough to cover such a range of subjects satisfactorily, and when the analysis of theory is carried to the extent attempted by Mr. Gray the result can not be a success. Considered as a text-book, it would be unsuited to the average fourth-year student, not because the analyses are too involved for such, but because their introductions are too brief. The calculation of temperature gradient may be taken as an example. If a few paragraphs had been inserted discussing the laws governing flow of heat, and containing perhaps a simple application, the subsequent treatment would have been much more easily understood. The same criticism is applicable to the chapter on armature reactions in alternators.

Considered as a book for reference purposes, this work contains much matter of value, both to the student and to the designer. Discussions of such questions as noise of induction motors, comparative value of shell and core type transformers, short pitch windings

in direct current machines, are really valuable and are not to be found readily elsewhere. The subjects of commutation and insulation are very well developed.

The arrangement of subject matter is usually excellent. The treatment of the induction motor had better have followed that of the transformer instead of preceding it. Such an arrangement would have made possible the consideration of the induction motor as a transformer, a most practical and effective method. The theory of operation and construction of each type of apparatus is first developed. This is followed by the procedure in design, the discussion of special types of machines, and a chapter on specifications. Examples accompany the text and should aid the student materially in his comprehension of the subject.

The book compares favorably with the other books on design in our language, but when it is contrasted with the simple and extremely logical treatments to be found in the works of Arnold, its own shortcomings are most apparent.

C. W. GREEN

#### METEOROLOGICAL OBSERVATIONS AT THE UNIVERSITY OF CALIFORNIA

It is probably due to the fact that the public interest in meteorology is centered around weather forecasts that the science has received so little attention from the universities of the United States. The University of California is one of the relatively small number which has maintained a regular series of observations for a considerable period.

Until July 1, 1912, when the routine meteorological work at Berkeley was transferred to the department of geography under which the courses in meteorology and climatology are listed, the astronomy departments, the Lick Observatory at Mount Hamilton and the Students' Observatory at Berkeley, carried on the principal meteorological observations of the university. Meteorological observations have always been a part of the regular work of the Lick Observatory and, when the Students' Observatory was established at Berkeley, its ac-

tivities included meteorological work as a voluntary observer's station of the United States Signal Service. The first rain-gauge was set up on October 16, 1886, and the meteorological work may be dated from that time. A synopsis of the results of the observations for the twenty-five years ending July 1, 1912, has been prepared by the director of the observatory and is soon to be published in the University of California Publications in Geography, which will contain, among other geographic papers, the results of the meteorological observations and climatic studies made at the University of California.

There is, perhaps, no type of work in which so much depends upon the daily exacting attention to detail as meteorology. An observation missed in this work is lost forever; an approximate figure may be obtained and used in the preparation of the averages, but the greatest value of meteorological work depends upon an unbroken and regular series of observations. Such a series is that which was obtained by the Students' Observatory at Berkeley during a period of nearly twenty-six years. From the establishment of the meteorological station until September, 1892, the observations were made three times daily, at 7 A.M., 2 P.M. and 9 P.M., and the results sent to the signal service at the end of each month. From September 1, 1892, observations have been made at 8 A.M. and 8 P.M., Pacific Standard Time, the standard time in use in the state of California. The transfer of the meteorological work from the signal service of the War Department to the Weather Bureau of the United States Department of Agriculture in no way broke the continuity of the record at Berkeley; the relations which were established with the signal service have been continued with the Weather Bureau.

The plans of the signal service for the work of the voluntary observers proved to be somewhat more detailed than seemed desirable under the conditions of the service and in the early nineties a simplified form of report was adopted. As far as the reports to the Weather Bureau were concerned the University of

California conformed to the new plan; but the observations at Berkeley were maintained on the same plan as before, as there was nothing inconsistent with this in the new form, with the result that the record kept by the university is exceptionally complete.

In addition to the reports which have been sent to the Weather Bureau and printed in its publications, the university has issued a monthly meteorological synopsis of Berkeley regularly since the beginning of 1887. General synopses have been prepared by Professor Leuschner, the director of the Students' Observatory, and published at five-year intervals, which have summarized the results, as shown by the monthly synopses, up to the date of the general summary. The monthly synopses have been continued by the department of geography in a somewhat enlarged form. It is also proposed to publish an annual report in conformity with the suggestion of the International Meteorological Committee. The original record is in such good condition that, when it was decided to change the method of compiling and stating some of the data in order to bring the form of the synopsis into accord with the better practise, this could be easily accomplished without the use of approximations, and without breaking the series.

There is no scientific work which will continue itself for any considerable length of time without the persistent efforts of men. The meteorological work at Berkeley depends largely upon the efforts of the directors and the Students' Observatory. With the advice of the signal service and the approval of the University of California Professor Frank Soulé, the first director, conceived the idea of making meteorological observations at the observatory, and began the work which has continued since that time. In 1892 he was succeeded as director by Professor A. O. Leuschner, who has maintained the record at its high standard for the past twenty years. The actual observations have been made by various members of the staff of the observatory; and their faithful and punctual performance of an exacting and often unin-

teresting routine duty gives the record its value.

The meteorological work has now come under the direction of the writer as a part of the work of the department of geography. The observations are made at 8 A.M. and 8 P.M., 120th meridian time, besides which there are continuous records of pressure, temperature and relative humidity from the recording instruments. The eye observations are now as follows: wet and dry bulb thermometer readings, maximum and minimum temperatures for the preceding twelve hours, air pressure, wind direction and estimated velocity, amount of cloud, weather and precipitation during the preceding twelve hours. The data are summarized and published monthly in the *Meteorological Synopsis* of Berkeley and a monthly report is made to the United States Weather Bureau on the regular form of report for the cooperative observers.

The University of California has for Berkeley and for Mount Hamilton meteorological records of considerable length and more complete than exist for many places in the United States not regular stations of the Weather Bureau. In a state where climate is such an important factor in the life of the people as it is in California, it is proper that the educational institutions, but above all the state university, should pay more than ordinary attention to meteorology. WILLIAM G. REED

REVIEW OF FOREST SERVICE  
INVESTIGATIONS<sup>1</sup>

THE new periodical issued by the Forest Service, the *Review of Forest Service Investigations*, is the direct outcome of the standardization and coordination of the investigative work done by the service. This investigative work has been placed on a more solid footing by the establishment of investigative committees in each district and of a central investigative committee in Washington.

<sup>1</sup> Volume I., issued March 11, 1913, by U. S. Department of Agriculture, Forest Service.

The *Review* is to serve as a medium for keeping foresters in touch with the scientific work of the profession in America. It will do this by publishing progress reports on major investigations the completion of which will require a number of years, during which time nothing would otherwise be known of them; by publishing full reports on minor studies not of sufficient importance to warrant publication as separate bulletins or circulars, but which nevertheless contain valuable material; and by giving a general view of the scientific forest problems in this country and of what is being done toward their solution. In short, the district and central investigative committees and the *Review* represent the crystallization of the scientific work of the Forest Service; they will make possible a very much higher degree of efficiency.

The present number, being the first, is purely preliminary. It gives no conclusions or reports of investigations, but shows the organization and classification of the scientific work of the Forest Service, the problems in need of solution, and, in general, the manner of attacking these problems. It gives the four main heads, Dendrology, Grazing, Products and Silviculture, with their subdivisions, and describes concisely the problems to be studied under each subdivision. Under Dendrology it shows the importance of studies of tree distribution and of wood structure. Under Grazing, work is being done to collect basic information on the forage, to find methods of reseedling the more valuable kinds, both artificially and naturally, and ways of handling stock so as to increase the carrying capacity of the range, better the condition of the stock, and insure complete utilization of the forage. Under Products, investigations are being carried on to learn the properties of wood, mechanical, physical and structural, so that each kind can be put to its best use and handled most efficiently in manufacturing and kiln drying; to increase the knowledge of preservatives, including the methods of using them and their effects; to develop uses for products of trees other than saw

timber, such, for instance, as making alcohol from wood waste; in addition, Products is gathering much statistical information of use not only to the Forest Service, but to all wood-using industries. Products comes in closer contact with the lumber industry than any other branch of the service and has already secured results of great value to lumbermen. Under Silviculture, the *Review* gives in some detail the important problems on which the service is working. It describes briefly the establishment and purpose of the experiment stations; under each head (forestation, forest influences, management, etc.) it not only gives the problems to be studied, but shows their importance and their relation to each other. The experiment being conducted at Wagon Wheel Gap to determine the influence of forest cover on run off and erosion is given rather fully. This is probably the most complete and far-reaching experiment of its kind in the world.

At the end of the *Review* is the investigative program for 1912. A study of this program will show the thoroughness with which the field is being covered.

#### A LABORATORY METHOD OF DEMONSTRATING THE EARTH'S ROTATION

THE two laboratory methods in general use for proving the rotation of the earth are Foucault's pendulum and gyroscope experiments. The first is inapplicable in many laboratories, because there is no convenient place to hang a sufficiently long and heavy pendulum, while the apparatus for the second is necessarily expensive. The following experiment is designed to provide a simple and convenient means by which the earth's rotation may be demonstrated in a small laboratory. The demonstration depends upon the fact that, if a circular tube filled with water is placed in a plane perpendicular to the earth's axis, the upper part of the tube with the water in it is moving toward the east with respect to the lower part. If the tube is

quickly rotated through 180 degrees about its east and west diameter as an axis, the part of the tube which was on the upper side attains a relatively westward motion as it is turned downwards (since it is drawing nearer the earth's axis). But the water in this part of the tube retains a large part of its original eastward motion, and this can be detected by suitable means.

Since the east and west axis itself is rotating with the earth, only that component of the water's momentum which is parallel to this axis will have an effect in producing a relative motion when the tube is turned. If then  $\alpha$  is the angular velocity of the earth's rotation,  $r$  the radius of the circle into which the tube is bent, and  $\theta$  the angular distance of any small portion of the tube from the east and west axis, the relative velocity between the water and the tube when it is quickly turned from a position perpendicular to the earth's axis through 180 degrees is

$$\text{Velocity} = V = \frac{\alpha r}{\pi} \int_0^{2\pi} \sin^2 \theta d\theta = \alpha r.$$

In order to prevent convection currents, it is best to hold the ring normally in a horizontal position, in which case the relative motion is of course  $\alpha r \sin \phi$ , where  $\phi$  is the latitude of the experimenter.

To perform the experiment, glass tubing 1.3 cm. inside diameter was bent into a circular ring 99.3 cm. in radius, and a short glass tube closed with a rubber tube and screw

FIG. 1

clamp was sealed into it to allow for the expansion of the water and to provide a place for filling. The ring was fastened with tape into notches in the wooden rod A (Fig. 1), which served as the horizontal axis, and was

supported by wires from the extremities of the cross rod *B*. The ends of the rod *A* were made adjustable perpendicularly to the plane of the ring, so that the ring might be made to swing on an axis parallel to its plane. The ends of the rod were swung in solid supports, adjustable to make the axis horizontal. In order that the motion of the water might be detected, a mixture of linseed oil and oil of cloves of the same density as water was prepared, and a few drops of the mixture were shaken up with the water with which the tube was to be filled. The globules of oil were observed at a point *C*, between the ends of the axis, through a micrometer microscope. Difficulties from the astigmatic refraction of the light by the water in the cylindrical glass tube were overcome by sealing a tubular paraffine cap, closed with a cover-glass and filled with water, on the part of the glass tube under the microscope, thus presenting a plane surface through which to make the observation. One side of the ring was weighted, so that on releasing a catch at the side of the observer the tube swung around through 180 degrees in a definite time, and was held again by the catch just under the microscope.

In taking a reading, the microscope was focused as nearly as possible on the center of the tube, and the ring was left in position until the oil globules had no appreciable motion. As soon as the catch which held the ring in position was released, the time was counted, with the aid of a metronome ticking half-seconds, until the tube had turned and an oil globule had been fixed upon to follow. The globule was followed through a measured length of time by turning the micrometer screw, and the distance through which it moved was recorded. Examples of these observations are given in the first three columns of Table I.

Variations in the readings arose from the fact that the part of the ring toward the east was near a cold wall, so that convection currents were produced as soon as the tube left the horizontal position in making a turn. This effect was made as small as possible by

stirring the air with an electric fan. Other variations came from the fact that it was found impossible to adjust the horizontal axis so nearly parallel to the plane of the ring as to prevent a slight effect from turning the

tube. Errors from the first cause were corrected by reversing the direction of turning in alternate readings. Those from the latter cause were nullified by taking readings with one side of the ring weighted and then shifting the weight to the other side. In this manner ten readings of each of four different kinds were taken (Cases I, II, III, and IV.), and the fact that the predominant motion is positive, or toward the west as observed on the south side, shows that the earth is turning from the west to the east.

#### *Calculation of the Initial Velocity*

In order to make an accurate estimate of the velocity corresponding to any given reading, the rate of decrease of velocity of the water in the ring must be determined. If the

retardation  $r$  is taken to be proportional to the velocity  $V$  for this low velocity,

$$r = \frac{dV}{dt} = CV,$$

$$\frac{dV}{V} = Cdt,$$

and

$$\log V = Ct + K$$

will express the value of the velocity at different times. In order to determine the constants  $C$  and  $K$ , the ring was held in a vertical position until the colder water near the east wall produced a considerable motion. It was then brought back to the horizontal and the time observed which was required to move successive quarter millimeters. A few

FIG. 2

such readings are given in Table II. From a large number of such observations an average curve was drawn, showing the relation of the distance covered to the time (Fig. 2, Curve A). The slope of this curve was taken at two

TABLE II

	.25	.50	.75	1.00	1.25	1.50	1.75	2.00	Distance in Mm.
1	2	4	7	11	16	22	30	42	Time in seconds.
2		2		5	7	10	15	21	
3	3	7	11	17	23	31	45	68	

of the most definite points,  $t=12.5$  and  $t=30$ , and these values were substituted in equation (1) to determine the constants  $C$  and  $K$ . The curve in Fig. 3 was then drawn from the resulting formula, showing the velocity at any time. Curve B, Fig. 2, was

then constructed by integrating this curve graphically with respect to  $t$ .

The water in the ring has its maximum velocity just before the turn is completed. The time required to make a complete turn was three seconds, and if this is subtracted from the time in column 1, Table I., it gives the length of time between the completion of the turn and the first observation of the motion (column 4, Table I.). Now if a portion of Curve B (Fig. 2) be taken, such that the distance represented on the curve in the time of any particular reading is the same as the distance in that reading, the beginning of that portion of the curve will correspond to the time at which the motion of the globules

FIG. 3

was first observed (column 5, Table I.). So if the number of seconds in column four is subtracted from the time corresponding to the beginning of the reading, the time corresponding to the completion of the turn is obtained, and the velocity at that time can be read from the curve in Fig. 3. This value is given in column six, and is the velocity at the time of completing the turn. The velocities in each of the four cases are averaged separately, and the average of the four averages is taken as the true motion due to the earth's rotation.

The average of the velocities in these four cases is .0513 mm. per second. From the formula  $V = ar \sin \phi$  derived above, we ob-

tain  $V = .0484$ , a difference of 5 per cent. As a check upon the accuracy of the readings, it will be seen that the differences between the velocities in Cases I. and II. and between those in III. and IV., representing double the velocity due to the difference in density of the water in different parts of the tube, are about equal; also the differences between Cases I. and III., and II. and IV., representing the variation due to imperfect adjustment of the axis, are approximately the same. In order to show that there was no appreciable effect from convection currents while the ring was in a horizontal position, several readings were taken after the tube had remained at rest for some time, none of which showed a motion larger than .015 mm. per second.

In order to obtain the best possible results, the ring should be mounted as rigidly as possible in a room of equal temperature throughout, and the axis should be capable of accurate adjustment parallel to the ring. If the radius of the ring were made smaller, although the effect of the earth's rotation would be less, it would be easier to keep all parts of the tube at an equal temperature, and the ring could be turned more quickly. Moreover, since the motion would not be so great, the velocity of the water would diminish less rapidly, so that more accurate readings could be obtained. With a more mobile liquid the motion would of course continue longer. Even with the comparatively crude apparatus described above, however, it is not difficult to show that the earth revolves.

#### CROSSOPTERYGIAN ANCESTRY OF THE AMPHIBIA

For many years evidence has been accumulating for the view that the Amphibia have been derived not from Dipnoi but from Crossopterygians of some sort. Pollard<sup>1</sup> held that the Amphibia were remotely related to the

living *Polypterus* and Baur<sup>2</sup> was able to strengthen the evidence, to some extent, from the Stegocephalian side. More recently Thévenin<sup>3</sup> has expressed similar views, while Moodie,<sup>4</sup> correcting Baur's observations on the lateral line grooves in the skull has seemingly demonstrated the general homology of the skull top of *Polypterus* with that of Stegocephalia. Gegenbaur<sup>5</sup> supported the homology of the Stegocephalian cleithrum with the "clavicle" of *Polypterus* and other fishes, while Klaatsch<sup>6</sup> showed that the pectoral limbs of *Polypterus* both in musculature and osteology in many respects remotely suggest Amphibian conditions. On the other hand, Goodrich's<sup>7</sup> studies on the scales of fishes, together with the evidence offered especially by the brain of *Polypterus*, tend to remove that genus widely from genetic relationship with the Amphibia.

The Paleozoic Crossopterygii have hitherto yielded a few, though significant, hints of Amphibian relationship. The Texas Permian Crossopterygian fish named by Cope *Ectosteorhachis nitidus* and recently figured by Hussakof<sup>8</sup> as *Megalichthys nitidus*, suggests remote Stegocephalian affinities in the skull and the same is true of *Rhizodopsis*, as figured by Traquair<sup>9</sup> and of *Osteolepis*, as figured by

<sup>1</sup>"Les Plus Anciens Quadrupèdes de France," *Annales de Pal. (Boule)*, tome V., 1910, pp. 1-64, pl. I.-IX.

Pander.<sup>10</sup> *Sauripterus* Hall, a supposed Rhizodont from the Upper Devonian of Pennsylvania has a pectoral girdle and forepaddle which distantly approach Stegocephalian conditions<sup>11</sup> and so also, but in less degree, has *Eusthenopteron*.<sup>12</sup>

Far more definite evidence of the supposed relationship of the Stegocephali with the Paleozoic Crossopterygii has recently been adduced by D. M. S. Watson,<sup>13</sup> of Manchester, in describing some of the large Stegocephalia of the Coal Measures preserved in the Newcastle Museum. He finds that the skulls of the Carboniferous Labyrinthodonts, "*Loxomma*" and *Pteroplax* reveal striking resemblances to the Carboniferous Crossopterygian *Megalichthys*:

The Basisphenoid of *Megalichthys* has sometimes carotid foramina just as in *Loxomma*. It has small but distinct basi-ptyergoid processes which are, however, not provided with articulating surfaces but with sutural ones. The long parasphenoid extends forward to the premaxillæ as it may do in *Pteroplax*. Its lateral borders are in contact with the Pterygoids, to which they afford support, and the bone is connected with the roof of the skull by a fused ethmoid.

The pre-vomer is identical with that of "*Loxomma*" in the majority of its attachments, carries one large tusk and a pit for the replacing tooth. It meets its fellow of the opposite side and forms the front of the posterior naris; it is doubtful, however, if it meets the palatopterygoid.

The Palatopterygoid of *Megalichthys* is exceedingly like the palatine and pterygoid of *Pteroplax*. They have similar relations to the basisphenoid, parasphenoid and maxilla. There is the same row of small teeth parallel to those of the maxilla with

larger teeth inside them, and the pterygoid is covered with the same shagreen of fine teeth.

Examination of these primitive and extremely well-preserved skulls seems to show that the ordinary idea of autostylism of the Tetrapoda is incorrect in postulating a connection between the pterygo-quadrate cartilage and the otic region. It is, I think, quite certain that there never was such a connection in primitive forms, except through the dermal bones of the temporal region. The lower attachment with the basisphenoid I have just shown to exist in Crossopterygians, which are hence "amphistylic," in a different way to Notidanus.

The large teeth on the palatine, with infolded bases, exhibit a curious type of tooth replacement which is

very characteristic of the Stegocephalia, and is unknown elsewhere except in the Crossopterygian fish, where it occurs in a very typical form in the vomerine tusks of *Megalichthys*, and no doubt in many other genera, and in *Lepidosteus*. This occurrence seems to me a strong additional reason for regarding the Tetrapoda as derived from this group of fish.<sup>14</sup>

The lower jaw of "*Loxomma*" likewise approaches the Crossopterygian type in the fact that the splenial is "entirely a bone of the outer side of the jaw as is the first infradentary of the Crossopterygian mandible."

Watson's observations also have important bearing on the relations of the Permian reptilia. These have been distinguished from contemporary Stegocephalians chiefly by the single basi-occipital condyle and by the large pterygoids, which leave only a small interpterygoid vacuity, divided by a narrow parasphenoid. Watson has shown that these and other "reptilian" characters are fully exhibited in "*Loxomma*," *Pteroplax*, *Anthracosaurus* and other Carboniferous Stegocephalians, that these characters they share also with *Megalichthys* and that no palate with large vacuities like that of *Eryops* or *Capitosaurus* has ever been found in Carboniferous rocks. He therefore concludes that "the reptilia were separated off very early in the history of the Stegocephalia, preserving features which were

<sup>10</sup> Ueber die Saurodipteren, Dendrodonten, Glyptolepiden und Cheirolepiden des Devonischen Systems," 1860, pls. 1-3.

<sup>11</sup> Cf. Gregory, SCIENCE, N. S., Vol. XXXIII, 1911, p. 509. A figure of this forelimb by Hussakof has recently been published by Dr. Bertram Smith in the *Journal of Morphology*, Vol. 23, No. 3, 1912, p. 544.

<sup>12</sup> Cf. Patten, "The Evolution of the Vertebrates," 1912, p. 391.

<sup>14</sup> *Ibid.*, p. 5.

rapidly lost by the latter group, which had a much accelerated evolution." With this conclusion the trend of recent work on the Permian Tetrapoda by Case, Williston, Moodie and Broom, seems to be in accord.

AMERICAN MUSEUM OF NATURAL HISTORY

### SOCIETIES AND ACADEMIES

#### THE BIOLOGICAL SOCIETY OF WASHINGTON

THE 508th regular meeting was held in the assembly hall of the Cosmos Club, February 22, 1913, with President Nelson in the chair and 76 persons present.

The program consisted of a lecture by Edmund Heller on "Hunting with Rainey in Africa." The communication was chiefly descriptive of the maps and numerous lantern slides exhibited and also of the physical features and vegetation of the country as well as the animals secured during the expedition.

THE 509th meeting was held March 8, 1913, with Vice-president Paul Bartsch in the chair and 37 persons present.

Under the heading "Brief Notes, etc.," Wm. Palmer exhibited the head of the small devil ray (*Mobula olfersi*) and a plaster cast made from the same, and explained the feeding habits of this fish. A. C. Weed gave some further account of its habits, and Theodore Gill added some historical notes about devil fishes.

Barton W. Evermann reported results of the sale of blue fox skins from the Pribilof Islands at Lampson's (London) auction of March 7. The 384 skins offered sold at an average price of \$56, the highest price being \$85.

The regular program consisted of two communications. J. W. Gidley gave an account of a fossil camel recently found in America north of the Arctic circle. The only bone found was a phalanx. The species was an extinct one and its occurrence so far north was regarded as further proof that there once existed land connection between the continents by way of Alaska. The paper was discussed by Messrs. Wilcox, O. P. Hay, Weed, Gill, Evermann, Lyon and others.

The second communication was by Paul Bartsch on "Some Remarkable Philippine Mollusks obtained by the U. S. Bureau of Fisheries Expedition." Specimens of the mollusks described were exhibited by the speaker.

THE 510th meeting was held March 22, 1913, with Vice-president Bartsch in the chair and 50 persons present.

Barton W. Evermann reported the executive order of President Taft made March 3, 1913, setting aside the entire chain of the Aleutian Islands as a wild mammal and bird reservation. The reservation is to be under joint charge of the Departments of Agriculture and of Commerce.

A. D. Hopkins announced the recent organization of a new scientific society, The Society for the Advancement of Forest Entomology in America.

The regular program consisted of two communications:

*Recent Progress in the Study and Culture of the Common Eel:* HUGH M. SMITH.

This was a comprehensive outline of the recent discoveries concerning and the completed life history of the common eel. Statistics of the commercial uses of the eel and the methods employed abroad for its propagation and distribution were given. Numerous lantern slides were shown.

*Tree-Shrews:* MARCUS LYON, JR.

This paper was based upon a study of many specimens of these squirrel-like insect-eating animals. Of less than 800 known specimens in museums, the British Museum possesses 355, the U. S. National Museum 24, and about 100 are in other collections. The paper was illustrated by lantern slides. Messrs. Bartsch and Wm. Palmer took part in the discussion.

THE 511th meeting was held April 5, 1913, with President Nelson in the chair and 43 persons present.

Under the head of Brief Notes, Paul Bartsch reported observations on the habits of the two common toads of the District of Columbia, *Bufo americanus* and *Bufo fowleri*.

Henry Talbott made some remarks on the probable agency of man in the dispersion of animals during the later geological ages. The regular program consisted of two communications:

*A Commercial Aspect of Paleontology: by a Layman:* HENRY TALBOTT.

*The Zoological Results of the Denmark Expedition to Northeast Greenland:* FRITS JOHANSEN.

The speaker, who accompanied the expedition, gave an account of climatic conditions and the fauna and flora encountered. Mammals and birds received the principal attention. Maps and numerous lantern slides were used.

ANNUAL SUBSCRIPTION, \$5.00

## Bacteriologies

### *Buchanan's Veterinary Bacteriology*

THE BEST  
PUBLISHED

This is a comprehensive work on bacteriology as applied to veterinary science. Immunity, opsonic index, the manufacture of antitoxins, vaccines and tuberculins; the process of reproduction, sterilization, antiseptics, biochemic tests, culture media, isolation of cultures, etc., are all presented. Besides bacteria and protozoa proper, Professor Buchanan considers molds and yeasts pathogenic for animals.

Octavo of 516 pages, with 214 illustrations. By ROBERT E. BUCHANAN, Ph.D., Professor of Bacteriology, Iowa State College of Agriculture and Mechanic Arts. Cloth, \$3.00 net.

### *Jordan's General Bacteriology*

NEW (3d) EDITION  
Adapted by U. S. Army

Professor Jordan presents fully the bacteriology of plants, milk and its products, dairying, agriculture, water, food preservatives; of leather tanning, vinegar making, tobacco curing; of household administration, and sanitary engineering. A chapter of prime importance is that on the bacterial diseases of plants.

Octavo of 623 pages, illustrated. By EDWIN O. JORDAN, Ph.D., Professor of Bacteriology, University of Chicago. Cloth, \$3.00 net.

### *McFarland's Pathogenic Bacteria*

NEW (7th) EDITION

Dr. McFarland's work from the first established itself as the standard in its field. This leadership has been maintained by frequent and thorough revisions, the present edition reflecting all that is new, all that is of practical value in bacteriologic endeavor. Much old matter has been eliminated.

Octavo of 878 pages, illustrated. By JOSEPH MCFARLAND, M.D., Professor of Pathology and Bacteriology, Medico-Chirurgical College, Philadelphia. Cloth, \$3.50 net.

### *Eyre's Bacteriologic Technic*

READY JUNE 15TH  
NEW (2d) EDITION

Dr. Eyre's book has been reset and enlarged by 150 pages and 50 illustrations. You get here all the newest technic for bacteriologic examination—and from the pen of a thorough technician.

12mo of 520 pages, with 219 illustrations. By J. W. H. EYRE, M.D., Bacteriologist to Guy's Hospital, London.

### *Gorham's Laboratory Course*

MEDICAL, AGRICULTURAL  
AND INDUSTRIAL

This book is a guide to the practical details of laboratory work, and is so arranged that it will meet the requirements of medical, agricultural and industrial students equally well.

12mo of 192 pages, illustrated. By FREDERIC P. GORHAM, A.M., Associate Professor of Biology, Brown University, Providence. Cloth, \$1.25 net.

W. B. SAUNDERS COMPANY, Philadelphia and London

## Recent Publications of the New York Botanical Garden

**Journal**, Vol. XIV, No. 160. An illustrated monthly containing notes and non-technical articles of general interest. \$1.00 a year.

## THE JOSEPH LEIDY LECTURE

INTRODUCTION BY THE PROVOST OF THE UNIVERSITY OF PENNSYLVANIA

JOSEPH LEIDY was a son of the University of Pennsylvania. As a token of reverence and affection his devoted nephew and namesake, Joseph Leidy, Jr., has generously endowed the Joseph Leidy Memorial Lectureship for the extension of scientific knowledge through the medium of lectures by eminent specialists.

To-night, we meet to inaugurate this foundation. Of Dr. Leidy, the great student and teacher, whom many of us knew and deeply honored, I would say:

"The wisest man could ask no more of fate  
Than to be simple, modest, manly, true,  
Safe from the many, honored by the few;  
Nothing to count in world, or church, or state,  
But inwardly in secret to be great;  
To feel mysterious nature ever new,  
To touch, if not to grasp, her endless clue,  
And learn by each discovery how to wait,  
To widen knowledge and escape the praise;  
Wisely to teach because more wise to learn;  
To toil for science, not to draw men's gaze,  
But for her love of self denial stern;  
That such a man could spring from our decays  
Fans the soul's nobler faith until it burn."

EDGAR F. SMITH

## A TRIBUTE TO JOSEPH LEIDY<sup>1</sup>

JOSEPH LEIDY was a Philadelphian by his birth, by his career and by his death, and no citizen of this metropolis has more deserved public honor than he.

Leidy was born September 9, 1823, and died April 30, 1891. His first scientific paper was published in 1845, and his last

<sup>1</sup> Opening address for the Joseph Leidy Foundation delivered at the University of Pennsylvania, April 17, 1913.

in 1891. For forty-six years he was an active contributor to *SCIENCE*. The list of his publications, prepared by his nephew, gives 597 titles. A large part of these are brief communications to the Academy of Natural Sciences in Philadelphia, but the list includes also a series of articles and memoirs, some of them of considerable extent, and all valuable. Leidy's investigations are among the classics of American science.

He represents a type of scientific man which seems in our days of specialization and of elaborate laboratories almost extinct. He was a naturalist, and was one of the group of four distinguished true naturalists who have done most for the introduction of natural science into American life. These four men—Louis Agassiz, Spencer F. Baird, James D. Dana and Joseph Leidy—were contemporaries. They all took a similar view of nature. She was a whole made up of many parts played together, and they were interested in the whole drama. Their delight was to go forth and see the world and watch the co-ordinated working of its parts. The correlation between living beings and physical forces appealed to them. They were quite untouched by what we may call the "laboratory spirit," which has arisen since their time—that spirit which isolates an object or phenomenon indoors in order to apply to it all the finest resources of modern scientific equipment. These men, on the contrary, went out of doors to see and study, and the spoils which they brought home were investigated without any elaborate appliances. Young zoologists, botanists and geologists of to-day find these methods too toilsome. In one passage Leidy points out that the studies of the living fauna of our streams and ponds may be carried on by a simple microscope, such as even our elementary students of

to-day would scarce deign to use, yet how varied, interesting, and even wonderful the observations which Leidy has recorded! One has only to look through his collected researches in helminthology and parasitology, published by the Smithsonian Institution in 1904, to gain a clear impression of the enormous extent and variety of these observations. He searched all sorts of animals, insects, vertebrates, molluscs and found a great number of parasitic plants and animals, concerning which he reports many original observations. Many of the species discovered were new to science and were named by him. Nearly the whole of the material he studied was collected by himself, for the most part on little trips he made in the neighborhood of Philadelphia. I quote his own quaint reference to these excursions:

"Going fishing?" How often the question has been asked by acquaintances, as they have met me, with rod and basket, on an excursion after materials for microscopic study. "Yes!" has been the invariable answer, for it saved much detention and explanation; and now, behold! I offer them the results of that fishing. No fish for the stomach, but, as the old French microscopist Joblet observed, "some of the most remarkable fishes that have ever been seen"; and food-fishes for the intellect.

Although professor of anatomy at this university for a long time (1858-1891), his heart was always in his natural-history studies. He did, to be sure, write a textbook of anatomy, undertaken, it is said, only after much urging by the publisher, but it was only an unessential episode in his life. Yet he knew how to use his anatomical opportunities, and he has given us valuable notes on the inter-maxillary bone in man, on the structure of the liver, on reversal of the viscera, etc. But his real life was the exploration of nature. He acquired intimacy not only with animals, the chief objects of his study, but

also with plants, stones and minerals. He collected extensively, his herbarium which he presented to the university contained over 1,500 species, all determined by himself, and his mineralogical collection has been described as "very fine and valuable" and was purchased by the National Museum in Washington. But his chief collections were of animals, especially of such as offered opportunity for microscopical study. The quotation read a few moments ago refers to his gathering of fishes—the particular "fishes" in this case were the Rhizopods. His monograph of this group of unicellular animalcules appeared in 1879 as one of the quarto volumes of the Hayden Survey, and contains a vast amount of original observation and is illustrated by thirty plates, after his own drawings of the living animals. Another extensive work was entitled "Flora and Fauna within Living Animals," one of the most important contributions to parasitology we possess. It was published in 1851 by the Smithsonian Institution in Washington, and is illustrated by ten exquisite copper plates, so skillfully engraved by Oudet that they worthily reproduce the author's beautiful drawings.

The range of work we have already indicated is sufficient to more than occupy an able man, and the results published by Leidy in the field of zoology proper would alone suffice to assure his place among the most distinguished investigators of America. His actual reputation, however, rests at least in equal measure upon his achievements in vertebrate paleontology, which received a richly deserved recognition when the Geological Society of London awarded him in 1884 the Sir Charles Lyell medal. His monographs on American fossil vertebrates laid the foundations of our present knowledge, and first marked out the way by following which Cope and

Marsh and their younger successors have attained distinction. Mention may be made especially of the first memoir of the series, "The Ancient Fauna of Nebraska, a Description of Extinct Mammalia and Chelonia from the Mauvaises Terres of Nebraska," published in 1854 in the sixth volume of the Smithsonian Contributions to Knowledge. The wonderful Eocene deposits of the Bad Lands had not been long known, and the collections available had been hardly more than skimmings from the surface. Leidy by the friendly cooperation of the few collectors of the time was able to inspect practically all the remains which had been gathered. The plates are superb lithographs drawn by the talented Sonrel. In 1855 followed the memoir on the Sloths, in 1865 on the Cretaceous reptiles, and other memoirs in later years (1869, 1873 and 1877).

A special extraneous interest attaches to Leidy's paper on the extinct sloths, for it includes a careful description of *Megalonyx Jeffersoni*, the first remains of which were discovered in Virginia and were described by no less a person than Thomas Jefferson at a meeting of the American Philosophical Society on March 10, 1797. The bones were soon after identified by Dr. Caspar Wistar as not those of a carnivore, as thought by Jefferson, but of a sloth. Casts of these bones were sent to Cuvier, who studied them. I am told that the originals, collected by Jefferson, are now in the collection of the Academy of Natural Sciences in this city.

It happened that the study of vertebrate paleontology in the seventies and eighties of the last century was pursued with great zeal, but also unfortunately with certain rivalries, which aroused acrimonious feelings, too often publicly expressed. Leidy shrank from controversy and it is said that rather than risk being entangled in dis-

putes, so little to his taste, he withdrew from paleontological work altogether.

Leidy was a student of facts, a lover of positive knowledge. His attitude is indicated by the following words from the preface to his article on the extinct mammalia of Dakota (1869):

The present work is a record of facts. . . . No attempt has been made at generalizations or theories which might attract the momentary attention or admiration of the scientific community.

Note the implied scorn of hasty speculation, and remember that in 1869 most biologists had been carried off their feet by the whirlwind of speculation which arose in the wake of the Darwinian theory. Leidy remained undisturbed, a firm devotee of objective research.

Leidy's connection with the Philadelphia Academy of Natural Sciences was long and intimate. His earliest publication known to me was a communication to the academy in 1845. Two years later he became chairman of the board of curators; the collections of the academy long profited by his devotion and wide knowledge of natural history. From 1881 until his death he was president.

For nearly fifty years Leidy was a constant attendant at the meetings of the Philadelphia Academy and very often had matters of interest to communicate, many of which are briefly recorded in the *Proceedings*. Sixty years ago the meetings of local scientific societies had an importance and a charm, which have been much diminished by the developments of the last twenty-five years. A generation ago there were fewer specialists, and narrow interests did not dominate the majority of scientific workers as much as to-day. When naturalists met they spoke a common language, and were mutually interested in one another's discoveries—sixty years ago. There were no national special societies,

and no express trains to bring the members together for three days, and to scatter them asunder for three hundred and sixty-two days—sixty years ago. The knowledge of the individual was less intensive, but his outlook was broader—sixty years ago. To this old order—now passed forever—Leidy belonged. The range of his interests and of his contributions, as revealed by a careful study of the *Proceedings of the Academy of Natural Sciences*, is astonishing, if viewed from the standpoint of coteremporary specialization. There are statements in his usually brief notes in the *Proceedings* concerning regeneration in Planarians, the formation of the cell wall after the division of the cells, on the occurrence of internal parasitic plants in various animals, on bacteria in the intestine of toads, the sense of smell in snails, on a new fossil, on the structure of cartilage, parasitic worms, sponges, Infusoria, Rotifera, Annelids, extinct reptiles, fishes, parasitic Hymenoptera—all incidental and in part accidental observations, but reported with unflinching accuracy.

It should be recorded that time has greatly emphasized the importance of some of Leidy's original discoveries, as of the existence of a bacterial flora in the intestine (1849). Particularly noteworthy are his experiments with cancer, made in 1851.<sup>2</sup> He transplanted small fragments of a human cancer under the skin of a frog and found that they maintained themselves for a long period. At the close of the communication, the author says:

The experiment not only proved the independent vitality of the tissues, which was generally admitted, but also rendered it extremely probable that cancer was inoculable, for, as in the experiments, the cancerous fragments continued to live when introduced into cold-blooded animals, they

<sup>2</sup> *Proceedings Acad. Nat. Sci., Philadelphia, V.*, p. 212.

would probably not only continue to live when introduced into warm-blooded animals, but would grow or increase in size.

The transplantation of tumors has become an important method of pathological research. We should not forget that Leidy originated the method.

Leidy's supreme gift was the ability to see, coupled with an inexhaustible delight in seeing. He saw so well not only with his eye, but with his intelligence and interpreting mind, that his published observations maintain a level of accuracy to which few naturalists have risen. His characteristic accuracy shows equally in his brief notes and in his extended monographs—it seems never to have failed. Dr. Thomas G. Lee says of Leidy's publications that they "probably contain fewer errors of fact and interpretation than those of any other writer on so many and such varied subjects." The joy of seeing is an inborn gift. It manifested itself very early in Leidy and was accompanied by a talent for drawing. This talent was so marked in the boy that his father withdrew him from school when he was sixteen, with the idea of educating him as an artist. But at this age he was already a naturalist, a student of nature by spontaneous instinct. He dissected cats, chickens and other animals and showed such intense interest in comparative anatomy that it was decided that the lad should study medicine. He attended lectures on medicine at the University of Pennsylvania and obtained the degree of doctor of medicine in 1844, and for two years actually practised. In 1846 he was demonstrator of anatomy in Franklin Medical College, and in 1847 he became a teacher in the university under Dr. Horner. In 1850 he had the great advantage of a trip to Europe with Dr. George B. Wood, to collect material to illustrate Dr. Wood's lectures. It gave the young

naturalist fresh stimulus, for he made the acquaintance of a number of famous anatomists and physiologists. The late Mr. Isaac Hinckley was fond of relating how Dr. Wood found it difficult to persuade Leidy to overcome his modesty so far as to send in his card also to Johannes Müller. Presently Müller came into the room, crying out, "Which is Leidy?" Extreme modesty was a marked characteristic of Joseph Leidy throughout his life, and was accompanied by an amiable unselfishness, which endeared him alike to his friends and his students. In 1858, after the death of Dr. Horner, Leidy was made professor of anatomy in the university and continued to fill the chair until his own death, thirty-three years later.

Leidy's death terminated the career of a man whose noble and unflagging devotion to science secured a rich harvest of discovery. He has left a message to us which I deliver to you in his own words:

The study of natural history in the leisure of my life, since I was fourteen years of age, has been to me a constant source of happiness; and my experience of it is such that independently of its higher merits, I warmly recommend it as a pastime, which I believe no other can excel. At the same time, in observing the modes of life of those around me it has been a matter of unceasing regret that so few, so very few, people give attention to intellectual pursuits of any kind. In the incessant and necessary struggle for bread we repeatedly hear the expression that "man shall not live by bread alone," and yet it remains unappreciated by the mass of even so-called enlightened humanity. In common with all other animals, the engrossing care of man is food for the stomach, while intellectual food too often remains unknown, is disregarded or rejected.

It is an honor to Philadelphia that the statue of Joseph Leidy stands by the great city hall. It is an honor to the University of Pennsylvania that his name is to be from this evening forth associated with the university's highest work. We are gath-

ered here to express our reverence for the man and our admiration for the scholar. It is our part to keep alive the tradition of truth-loving, of scientific devotion and of perfect modesty which is our legacy from Joseph Leidy.

CHARLES S. MINOT

HEREDITY AND MICROSCOPICAL  
RESEARCH<sup>1</sup>

I have been much honored by the invitation to deliver the first lecture of a series established in honor of Joseph Leidy, a man distinguished alike for the diversity and importance of his original contributions to knowledge and for the far-reaching influence that he exerted on other men of science, in his own time and after. No American naturalist could be named whose biological interests ranged over a wider field; and the selection of my topic this evening has been influenced in some measure by the fact that Leidy was an almost solitary pioneer of microscopical investigation in this country, at a time when the cell-theory was in the earliest stages of its development, and when no one could have imagined the brilliant future that lay before it. Did time permit I would gladly dwell for a moment on his early observations on the structure and division of cells, and on the activities of the simplest forms of life. Much of his subsequent work lay in a very different field of inquiry, but his interest in microscopical investigation never deserted him, witness to which was borne by the publication in his later life of a beautiful monograph on the fresh-water rhizopods, which at once took its place as one of the classics of American zoology.

<sup>1</sup>A lecture delivered before the University of Pennsylvania, April 17, 1913, on the Joseph Leidy Foundation. With the exception of three general diagrams it has been impracticable to reproduce the figures that were shown by means of lantern slides.

More than half a century has passed since Leidy's earliest studies with the microscope. The main motive power behind the unparalleled advance in biology during this period has been the persistent effort to explain the activities of living things through investigations upon their structure, whether anatomical, physical or chemical. This effort entered upon a new era with the discovery of protoplasm and the promulgation of the cell-theory; for its final objective was now seen to lie in minute structural elements, the cells, of which the tissues are composed. Little by little it became clear that the cell, whatever else it be, is a microscopic chemical engine, where the energy of the foodstuffs is finally set free, and applied to the work of life. The question inevitably arose whether we can discover within the cell any visible apparatus by which this is accomplished. The inquiry has a thousand aspects; I ask your attention to that which relates to the problem of heredity.

It long since became clear that the cell-theory offers us a general explanation of heredity. Heredity is a consequence of the genetic continuity of cells by division, and the germ-cells form the vehicle of transmission from one generation to another. This fundamental discovery divested heredity of the mystery in which it had so long been enveloped, though it must always remain among the most wonderful of phenomena. But this result only cleared the way for further advances. Our scientific curiosity is aroused in the highest degree by more specific problems of heredity. Why do individuals now and then appear that show little resemblance to their immediate progenitors but "revert" to much more remote ancestors? Why do the grandparents often exert definite effects upon their grandchildren of which no suggestion is given by their children? What

explanation can be offered of the combinations and recombinations of parental or grandparental characters that appear in definite numerical proportions in hybrids? We may glance at a few particular cases that will serve to place some of these questions before you in more concrete form. In the first view we see the results of crossing two distinct races of sweet peas, each of which is pure white and produces only white offspring so long as strictly inbred. On crossing the two races the hybrids are always deep purple, like the wild Sicilian species, and in this respect they no doubt revert to an early common purple ancestor of the two white races. The offspring of the hybrids include a variety of purple, red and white forms, among which are whites that are identical with the two original grandparents. Here is a somewhat similar case in domestic fowls. You see two different white races, each of which breeds true; but when crossed together they produce deeply colored hybrids, showing a pattern of plumage that is closely similar to that of the wild jungle fowl from which both white races are probably descended. How is the reversion shown in this and the preceding case to be explained?

Let us look at some more complicated phenomena. We have here the result of crossing two differently colored races of fowls, the barred Plymouth Rock and the black Langshan. If the barred cock be paired with the black hen, all the offspring are barred, like the father. If the barred hybrids be paired together the progeny includes, on the average, three barred to one black, and the black bird is *always a female*. Quite different, and even more singular, is the reverse cross shown in the next view, where the black cock is paired with the barred hen. Half the offspring are now barred and half black; and the remarkable fact is that the barred birds are all males,

the black ones all females. In color pattern the sons are like their mother, the daughters like their father—an example of the so-called “criss-cross” heredity. Upon pairing these hybrids together, the following generation (grandchildren of the original forms) includes males and females of both types, barred and black. In the following view we see a quite analogous form of heredity, observed by Morgan in crossing a long-winged and a short-winged race of fruit-flies (*Drosophila*). When the male of a long-winged race is paired with the female of a short-winged race, all the sons are short-winged like their mother, all the daughters long-winged like their father. On pairing these two, the offspring are of all four types, long wings and short wings occurring in both males and females.

Such results seem at first sight capricious, almost fantastic, but this first impression is erroneous. The results are not capricious, but constant. The experiments may be performed over and over again, always with the same result, so that the outcome may be unfailingly predicted in advance; and this demonstrates that such forms of heredity, and heredity in general, must be due to some definite apparatus in the germ-cells. I shall try to show that microscopical research has revealed to us at least something of the nature of this mechanism, and that it has practically solved some of the very puzzles that have just been propounded. In order to indicate the nature of this solution, I must first ask attention for a moment to the so-called “unit-characters” and their behavior in heredity, on which the attention of both cytologists and experimenters on heredity has been largely concentrated in recent years.

Unit-characters have become too familiar to require more than brief illustra-

tion. Examples of them have just been seen in the colors of flowers or of plumage, and in the structure of the wings in flies. Their interest lies especially in the fact that they are transmitted independently of one another, as if they were separate and independent things. By appropriate crossing experiments, such as we have just seen, particular groups of such characters may be split up and recombined, over and over again, in constantly new combinations, with no alteration of their individual character. Let us look at one or two examples of this. Here are the results of crossing two different races of wheat (from experiments by Biffen). One parent is a bearded variety with short, dense heads; the other a beardless form with long, loose heads. The hybrid is intermediate in shape, and is beardless. On pairing the hybrids together all combinations of the four original characters, and of the hybrid character, appear in the grandchildren, namely, (1) short beardless, (2) short bearded, (3) hybrid bearded, (4) hybrid beardless, (5) long bearded and (6) long beardless. These six types appear in definite numerical ratios, and it is evident that the bearded or beardless character has been transmitted quite independently of the shape of the head.

Another and very striking case of the same kind is here seen, again from Morgan's experiments on fruit-flies. The grandfather has white eyes and yellow body color; the grandmother red eyes and gray body color. In the first generation all the offspring have red eyes and gray color. Among the grandchildren, however, appear not only both the original combinations but two new ones, namely, white-eyed grays and red-eyed yellows. Here again the second generation of hybrids shows all possible combinations of the four original unit-characters, white eye, red eye, yellow color and gray color. With a

larger number of unit-characters the same would hold true, but the number of combinations would be much larger.

We catch a glimpse here of the methods by which the modern breeder of plants or animals is able to break up known combinations and recombine them into new types, somewhat as the organic chemist splits up known organic compounds and recombines the products into new compounds, perhaps unknown before. Our ability to do this is often of high practical value. As de Vries has said, most hybrids owe their character to a new combination of qualities. "It is the combination that is new," he says, "not the qualities themselves. Some characters are derived from one parent, others from the other. Each of these may be simply inherited, . . . but by their new combinations they yield varieties of higher practical value, and notable examples are afforded in those cases where one parent has contributed vigor of growth, hardiness in winter, resistance to disease or productivity, and the other bright flowers, palatable fruit or nutritive seeds." An example of this which he cites is Luther Burbank's celebrated white blackberry, produced synthetically by uniting in one race the light color of the fruit of an inferior variety of cultivated bramble with the large and succulent fruit of the Lawton blackberry. Another familiar example, also cited from Burbank's work, is the so-called Shasta daisy, which unites the desirable qualities of plants from three different continents. An English daisy has contributed its large flowers and tall, stiff stems; a Japanese species its whiteness of bloom; an American field daisy its profusion of flowers and hardiness in winter. Many other examples might be given to illustrate how by disassociation, recombination and selection desirable qualities may be brought together and undesirable ones eliminated; and by

this principle the improvement of domestic races of plants and animals is being attempted in many parts of the world to-day.

Now, it is obvious that we should be able to understand the behavior of unit-characters, at least in some degree, if it could

question how the splitting up and recombination of particular groups of such characters takes place. The main part played by microscopical research has been to bring forward proof that the hereditary characters are somehow connected with separate bod-

FIG. 1

be shown that they are somehow dependent individually upon separate structural elements or different chemical substances that may be separately transmitted through the germ-cells. It is just this which microscopical research and experimental researches on heredity, taken together, have demonstrated. They have accomplished more than this. They have not only shown with a high degree of probability how the transmission of unit-characters is effected, but have thrown at least some light on the

ies, contained in or formed from the cell-nucleus, and known as the *chromosomes*. Besides the chromosomes the cell also contains another kind of bodies found in the cell-protoplasm, and known as *chondriosomes* or *plastosomes*. These too are very likely connected with heredity; but their true significance has not yet become very clear, and we shall hardly have time to consider them within the limits of this address.

With the aid of the accompanying diagram (Fig. 1) we may consider a few es-

sential facts concerning the chromosomes, leaving aside most of the complicated technical details. In each species of plant or animal the chromosomes are of constant, or nearly constant, number. They divide as the cell divides, and are thus transmitted from cell to cell. In the fertilization of the egg two similar groups of chromosomes are brought together, one contributed by the egg, one by the sperm-cell; and as the egg step by step divides to build up the body

against it must give way before the fact that in certain hybrids—in particular, certain fish-hybrids observed by Moenkhaus—the chromosomes of maternal ancestry can actually be distinguished by the eye from those of paternal. Finally, when new germ-cells are produced for the formation of the following generation the double chromosome-groups are again reduced to single ones in preparation for the succeeding process of fertilization.

FIG. 2

of the embryo the chromosomes also divide at each cell-division. Every cell-nucleus thus receives a double group of chromosomes, consisting of two single groups descended respectively from the two groups that originally came together in the fertilized egg. The two single groups of each nucleus are thus of maternal and of paternal ancestry, respectively. This all-important conclusion has been obstinately contested and is still denied by a few writers. I think, however, that all arguments

These are not theories but observed facts. It is impossible to overlook the very precise parallel which they show to what Gregor Mendel and his successors have proved to be true also of the unit-characters, as will be made clear by the accompanying diagram (Fig. 2). When two similar or nearly similar individuals unite in fertilization they contribute to the germ two corresponding groups of unit-characters, which are designated in the diagram by two series of letters A-D and a-d, respectively. The

offspring are therefore of double or "duplex" hereditary constitution. When the germ-cells are formed, as Mendel first proved by experiments on hybrids, they are found to carry only a single or "simplex" group of characters. So closely parallel is all this to what we have learned about the chromosomes that we can just as well use the diagram for the chromosomes as for the characters. Chromosomes and characters alike form a single or simplex group in the germ-cells, a double or duplex group in the body of the offspring; and this alone is sufficient to make it extremely probable that chromosomes and characters are somehow connected. Exactly what is the nature of this connection we are not able to say with certainty; but we might reasonably assume, for instance, that each character depends upon some particular chemical substance, or group of substances, contained in the chromosomes, and that different chromosomes differ in respect to the substances which they carry. Such an assumption would be thoroughly in accord with the principles of chemical physiology and with the results of experiments upon the physiology of development.

The diagram brings out another fundamentally important fact that was also proved by Mendel's experiments, namely, that in the formation of the simplex character-groups all possible recombinations of the original parental unit-characters (within the limits of a single complete group) are effected. Only a few of the germ-cells receive the original combinations unchanged (A-D or a-d). In most cases new simplex groups are formed by recombination, such that each germ-cell receives always a complete single series (from A or a to D or d), but any particular member of the series may be derived from either parent. The number of such possible combinations varies, of course, with

the simplex number of unit characters; with 4 characters, as in the present case, it is 16; with 15 characters it would be more than thirty thousand. Any individual may thus produce many different kinds of germ-cells, equivalent in a general way but differing slightly in respect to their individual hereditary components. This result follows from the fact, discovered by Mendel again, that corresponding or homologous parental components of the duplex groups (such as A and a, or B and b) never enter the same germ-cell; and this is the essential fact in "Mendel's Law." We could readily understand this if before the germ-cells are formed corresponding parental components become associated in pairs (Aa, Bb, etc.) and then separated or disjoined in an ensuing process of division. If the process of disjunction took place in each pair independently of the others, all combinations would obviously be produced in the resulting germ-cells. Now, it is certain that something like this actually takes place in the case of the chromosomes. In the process known as *synapsis*, which takes place shortly before the last two cell-divisions concerned in the formation of the germ-cells, the chromosomes do in fact unite in pairs, two by two. There is reason to believe that the two members of each pair are respectively of maternal and paternal derivation; and the probability of this view, first stated by Montgomery, has steadily increased. Observation has made it extremely probable that in the course of the following two divisions the two members of each pair, or two somethings that they contain, are separated so as to pass into different germ-cells (Fig. 1). One of the most interesting recent discoveries in cytology is the fact that in some animals and plants a paired arrangement of the chromosomes is assumed long before the period

of synapsis, and may even be seen more or less distinctly throughout the life of the organism.

As has been said, the remarkable parallel between chromosomes and unit-characters constitutes in itself strong (though indirect) evidence that the latter depend in some way upon the former. Specific experimental evidence directly demonstrates the correctness of this conclusion. If, for instance, the orderly distribution of the chromosomes in the fertilized egg is artificially interfered with (as may be done in several ways) the development of the embryo is correspondingly disturbed. Boveri has proved that when abnormal combinations of the chromosomes are thus produced in the fertilized eggs of sea-urchins the offspring are almost always abnormal, deformed or monstrous. Recent experimental studies have proved by various methods that certain interesting abnormalities shown in hybrids are preceded by corresponding disturbances in the chromosomes. Again, it is now possible to fertilize the eggs of such animals as sea-urchins by the spermatozoa of animals as widely different as worms or mollusks. The offspring of such "heterogeneous" crosses show only the characters of the mother. They are typical sea-urchin larvae; and the explanation, demonstrated by microscopical observation, is that only the chromosomes of the mother are able to survive in the fertilized egg. Those of the foreign father (*i. e.*, of the sperm cell) sooner or later perish and degenerate within the egg.

Still another fact, of the same unmistakable import, is the recently demonstrated relation between the chromosomes and sex. Sex is now definitely known to be inherited like other characters; and within a few years the decisive proof has been attained that the heredity of sex is connected with a particular chromosome

known as the "sex-chromosome" or "X-chromosome." In a large class of cases, to which man almost certainly belongs, the male contains but one of these chromosomes, the female two; hence in such cases the total number of chromosomes in the female is one greater than in the male. In respect to these particular chromosomes, accordingly, the male always remains of simplex composition (XO), while the female is of duplex (XX). Observation has proved further than when the duplex chromosome-group of the female are reduced to simplex ones each mature egg retains a single X-chromosome, while in the male only half the spermatozoa receive X and half do not. From this it follows that when the egg (X) is fertilized by a sperm-cell containing X the result is a female (XX), while if fertilized by a sperm-cell without X, the result is a male (XO). I shall try to show a little later how clearly and simply these facts explain certain very curious special phenomena connected with the heredity of sex.

The specific and direct evidence thus briefly outlined has definitely established the fact that the chromosomes are causal agents in heredity; and it has already become evident that the study of their modes of distribution, combination and recombination provides us with a key which will unlock many special puzzles of heredity which would otherwise seem to us insoluble. I will attempt to make this clear in greater detail by considering three of the particular cases that have already been touched upon, taking them up in the order of their difficulty.

The simplest of these cases is that of reversion, illustrated by the sweet peas. It is evident from the experimental results that the purple color of the flowers requires the cooperation of at least two things, either of which alone is unable to produce

any color. These two things may for the moment be called "A" and "B." Both A and B must obviously have been present in the original purple race from which the two white races are descended. One race has at some time in its past history lost A, the other B; and each loss has produced a specific type of white race which breeds true. By crossing the two A and B are again brought together, thus restoring the original combination AB; hence the "reversion" to the purple wild type. Now, the things which we have called "A" and "B" may very well be different chemical substances. If we assume them to be borne by different chromosomes, brought together in the hybrid, the whole matter becomes at once clear and simple. It seems probable that all kinds of reversion may be explained by the same principle.

The second case is that of "criss-cross" heredity in the short- and long-winged flies, where the sons are like their mother, the daughters like their father. The explanation of this case is less easy to follow than that of reversion, but is more specific. This case, and many others of similar type, may be completely explained through our knowledge of the relation of the chromosomes to sex. These flies agree with the general rule already referred to, that the males contain a single X-chromosome, or sex-chromosome, the females two. All the facts revealed by experiment are very simply and completely accounted for by the single assumption that the X-chromosome is responsible not only for sex, but also for the short-winged character. Specifically, the assumption is that the short wings are due to the lack or defect of something (let us again say some definite chemical substance) that is contained in the X-chromosome. Let us see just how this works out. We may write the formula for the short-winged female as  $xx$  (the small

letters indicating the defect in X that is responsible for defective wing development), while that of the normal (long-winged) male is XO. Such a female produces eggs of only one type,  $x$ , while the normal male produces sperms of the two types X and no X or O. Fertilization thus can only give rise to the two combinations  $xX$  and  $xO$ , the former being females, the latter males. The males are short-winged because they contain only the defective  $x$ . The females likewise contain such an  $x$ , but they are nevertheless long-winged because they also contain a normal X, which is sufficient to ensure normal wing development. It follows that the daughters are long-winged like their father, the sons short-winged like their mother. I need not trace this explanation further into its details. It is enough to say that upon this one assumption the results of many other kinds of crosses among these flies work out perfectly; and a similar explanation will completely account for other cases of criss-cross fertilization, for such curious phenomena as the heredity of color-blindness in man, and many other cases in which particular somatic characters are linked with sex in a definite way. These cases offer, indeed, a brilliant example of the clearness and simplicity of the causal explanations that microscopical research has helped to give of complicated special phenomena of heredity.

As a third and last example I select an even more interesting and instructive case, the complete analysis of which carries us to the firing line of research in this field. It illustrates the influence of the grandparents upon the combinations of unit-characters seen in the grandchildren. It is a very curious fact, only recently discovered, that in certain cases hybrids of identical composition exhibit marked differences in their output of offspring that can

only be explained by an exact knowledge of the grandparents. We have already seen a concrete example of this; but before returning to it the essential result may be explained by means of a diagram. Let us consider the case of a hybrid that contains four characters, which we will designate as A, a, B and b. The hybrid AaBb can be made in two ways, according to the composition of the parents. First, one parent may contribute AB and the other ab; or, secondly, one parent may contribute Ab and the other aB. These two crosses seem to give precisely the same result, AaBb. The hybrids produced by the two methods look exactly alike; they produce the same kind of offspring (grandchildren of the original forms). The remarkable fact is, however, that in some cases (probably in many) the offspring of the two kinds of hybrids differ in respect to the numerical proportions in which different combinations of the grandparental characters appear. In both cases the grandchildren are of four visibly different types, AB, aB, Ab and ab. Following the first cross, however ( $AB \times ab$ ), the classes AB and ab are in great excess among the grandchildren, sometimes in very great excess; while following the second cross ( $Ab \times aB$ ) it is the classes Ab and aB that are in excess. In other words, in each case a large majority of the grandchildren are of the same type as their grandparents, while a small minority show new combinations of the grandparental characters. To change the statement, if A and B enter the hybrid together they tend to come out together in the grandchildren; if they enter separately they tend to come out separately. Why should this be so?

The facts will become clearer if we look again at the actual case of the fruit-flies already referred to, which was worked out by Professor Morgan. The grandfather

combines white eyes and yellow body color; the grandmother red eyes and gray color. White eyes and yellow color here enter the hybrid together, while white eyes and gray color, or red eyes and yellow color enter separately. The hybrids in the first generation all show red eyes and gray color, like the mother. On pairing the hybrids together, all four combinations appear—red eye and gray color, white eye and yellow color, white eye and gray color and red eye and yellow. The last three of these are *seen* only among the males; for although also present among the females they do not come into actual view, because in this sex white eye or yellow color is dominated or concealed by red eye or gray color. We may therefore confine our attention to the males. Now, on counting the relative numbers of these types among the grandsons a remarkable result constantly appears. An enormous majority of them—more than 100 to 1—show the same combinations as the grandparents, namely, white eye and yellow color, or red eye and gray color; while the two new combinations, white eye and gray color, and red eye and yellow color, are correspondingly rare. This, I repeat, is obviously because the characters that enter the hybrid together tend to come out together in the grandchildren; those that enter separately tend to come out separately. This at once suggests that the difference of result depends upon whether the two characters in question are borne by a common carrier in the germ-cells or by different carriers. White eye and yellow color tend to hold together because they enter the hybrid in some common carrier. White eye and gray color, or red eye and yellow color tend to remain separate because they enter the hybrid in different carriers. What are these carriers? Very extended experiments, analogous to that just de-

scribed, and involving the breeding of many thousands of these flies, have steadily increased the probability that these carriers are nothing other than the chromosomes. These experiments make it almost certain that in the cross we have been considering white eyes and yellow color are alike determined by the same chromosome, while red eyes and yellow color must obviously have been carried originally by different chromosomes, since they came from different grandparents.

There is here, as in the case of the short-winged flies, almost conclusive proof that a single chromosome may be responsible for the heredity of more than one character; and experiments of the same type have proved that a single chromosome may be responsible for many characters—at least twenty, and probably many more. Independent microscopical investigation has provided a very definite basis for this conclusion, having made it almost certain that the chromosome is a compound body, which includes many smaller elements, perhaps different chemical substances, each of which may play a definite part in determination. Both kinds of evidence indicate that these different elements are arranged in the chromosomes in linear series and in a definite way. The chromosomes arise from long threads, which split lengthwise throughout their whole length during division. In this way all the separate elements or substances which they contain may be equally divided and distributed to the daughter cells.

And this leads us finally to one more point that now forms a center of interest in these studies. Although (in such cases as we have been considering) characters that enter the hybrid together tend to come out together in the grandchildren, they do not always do so. As we have seen, in a few of the grandchildren characters that

were originally associated have separated so as to produce new combinations—such, for example, as the white-eyed gray flies, or the red-eyed yellows. How can this be reconciled with the conclusion that they were originally borne by the same chromosome? A possible answer to this question has been offered by Janssens's theory of the "chiasmatype," which has been more specifically and very ingeniously worked out by Morgan and some of his pupils. Reference has already been made to the fact that at a certain period, shortly before the germ-cells are formed, corresponding maternal and paternal chromosomes become coupled in pairs, side by side (synapsis). This process is always followed by a more or less intimate union of the two threads, perhaps in some cases by actual fusion. The evidence is still more or less conflicting as to exactly what follows; but it is certain that at a later period two separate and parallel threads again become distinct, and these *may* separate so as to pass unchanged into different germ-cells. These two threads are believed by many observers to be identical with those that originally united in synapsis, but this is in dispute. The fact of particular interest in this connection is that the two threads often become twisted around each other like the strands of a rope; and the observations of Janssens indicate that in some cases these threads may fuse at certain points where they cross and then split apart at these points in the longitudinal plane. By this process, as will be made clear by the accompanying diagram (Fig. 3), the possibility is given of an *orderly* exchange of certain regions of the threads between the two chromosomes of each pair. Now, it has been suggested that in this way two chromosomes that originally carry (let us say) AB and ab, may undergo such an exchange as to produce the new chromo-

somes *Ab* and *aB*, as shown in the upper part of the diagram. If this should happen only occasionally it would fully explain how it is that two characters borne by the same chromosome tend to remain together,

of a series of undoubted facts; and it is certainly worthy of the most attentive further examination.

The three cases that have been considered have led us, step by step, to the border

FIG. 3

yet *may* separate so as to pass into different chromosomes and hence into different germ-cells. As shown in the lower part of the diagram, a similar explanation may be extended to much larger series of characters, the behavior of which in detail may depend upon their arrangement in the threads, or on the character of the twisting. On the basis of this hypothesis an attempt has recently been made by Sturtevant to calculate from the observed results the degree and character of the twisting of the chromosomes, and the relative position of the different specific elements within them. This, admittedly, is a bold venture into a highly hypothetical region. Its justification is the pragmatic one that it "works." The hypothesis gives us the only intelligible explanation that has yet been offered

line of research in this field. I have not hesitated, in discussing the last case, to advance beyond the solid ground of observed fact into a debatable and hypothetical region; for it is by just such venturesome advances that new possibilities of discovery are opened. We have much to gain and nothing to lose by the use of explanatory hypotheses that are naturally suggested by the facts and help us to formulate them for analysis, so long as such hypotheses are not allowed to degenerate into dogmas accepted as an act of faith, but are only used as instruments for further observation and experiment. The "chiasmatype" hypothesis is no more than this; and though it is directly suggested by observed facts it remains for the present unproved. The more general conclusions that have been indi-

ated regarding the chromosomes stand, however, upon much firmer ground. That the chromosomes are in fact causal agents in determination can now be doubted, so I think, only by those who refuse to reckon squarely with the whole body of evidence. That the distribution of the chromosomes, or of smaller elements that they contain, gives us at least a partial explanation of the behavior of unit-characters has become in a high degree probable. The stubbornness with which each step in the establishment of these conclusions has been contested has been largely due, I think, to a misapprehension for which the advocates of the chromosome-theory are themselves in part responsible. The chromosomes have often been spoken of as if they were central, controlling factors in heredity, or as if they were actual bearers of the unit-characters—the latter form of expression has in fact been employed, for the sake of brevity, in the foregoing discussion. But it seems to me that such expressions are, to say the least, misleading; they are certainly unnecessary. It is perfectly obvious that chromosomes do not bear hereditary characters as such; they bear only *somethings* that are necessary to the production of characters. I again repeat that these “somethings” may be at bottom of chemical nature. We find it convenient, in order to avoid circumlocution, to speak of these things or substances as “determiners”; and there is no objection to doing this so long as we do not forget that many other things are concerned in the production of every character. Experiment has made it certain that the cell protoplasm is thus concerned. It is possible that the chondriosomes or plastosomes may here play an important part. In any case, the conclusion is not to be escaped, I think, that the whole cell-system is directly or indirectly involved in the production of

every hereditary trait. To treat the chromosomes as if they were central governing or controlling factors in the cell is a procedure of more than doubtful expediency. For the present, at least, all the requirements of investigation are sufficiently met if we think of the chromosomes, or that which they carry, only as *differential factors* in heredity, not as its primary or exclusive “determiners.” Whether they possess a significance more fundamental than this is a question that may well await the results of further inquiry.

I can refer here to only one or two of the many disputed questions of detail regarding the chromosomes. One of the most important is whether the chromosomes retain their individuality intact in the nuclei of the “resting period” or interkinesis that intervenes between successive cell-divisions. Some of the most careful recent cytological studies in this direction seem to show that such is not the case. Nevertheless these same studies, together with recent experimental evidence, give very strong ground for the conclusion that a definite relation of genetic continuity exists between the individual chromosomes of successive generations of cells. On the one hand, the cytological studies of Boveri, Bonnevie, Vejdovsky and others, almost conclusively prove in certain cases that each chromosome is formed directly from the substance of a corresponding chromosome in the preceding generation. On the other hand, cytological and experimental evidence combine to show that alterations of the chromosome-groups, involving the addition to or subtraction from the group of one or more *particular chromosomes*, are perpetuated generation after generation of cells, even throughout the life of the individual. Nature performs such an experiment every day in the production of sex; for the particular chromosome-com-

binations established by the entrance into the eggs of spermatozoa with or without the X-chromosome persist throughout the whole development of the individual until new germ-cells are formed.

A second fundamentally important question, concerning which no general consensus of cytologists has yet been reached, relates to the mode of union of the chromosomes in synapsis and the subsequent distribution of their substance to the germ-cells. Only in a few special cases has complete proof been attained of a conjugation followed by complete disjunction or separation of the original conjugating chromosomes. Until this complicated and difficult problem has been much more thoroughly studied we shall not be in a position to explain exactly what is the mechanism of Mendel's law of heredity and the distribution of the unit-factors to the germ-cells. We are not dealing with a closed chapter in the study of heredity. Both genetic and microscopical research are still in a formative stage. It is hardly a decade since they finally converged upon the same specific problems. We must not yet make too exacting a demand upon the explanatory capacity of either; and it is a part of the present interest of the subject that so much still remains to be accomplished.

We have thus arrived at some of the most advanced and difficult questions in this field of inquiry. Perhaps I have not succeeded in making entirely clear even the few illustrative cases that have been considered. If so, I must plead in extenuation that the subject is beset with technical difficulties; and we biological folk have come to speak a language that is strange to many of our fellows. But I have been less concerned with the presentation of particular results or the critical discussion of details than with the indication of a point of view; I have only wished to point out one of the pathways along

which students of cytology are attempting to cooperate with students of genetics in their attack upon the problems of heredity. I would like to urge in closing that such explanations as have here been briefly indicated are not mere vague and general notions. They are specific and detailed interpretations of observed facts. They enable us, up to a certain point, to comprehend what goes on in the germ-cells, to form perfectly clear mental pictures of the apparatus of heredity, and of its mode of action in particular cases. They contain no mystical or transcendental element. I repeat that they are entirely in accord with the principles of chemical physiology, and with the experimental results upon the physiology of development. To this extent at least the explanations are real and represent a partial solution of the problem of heredity. No one would maintain that these explanations are final. I do not doubt that with advancing knowledge we shall in time come to look back upon many of our present conceptions as crude and naïve. Discovery in this great field of research has made no approach to its limit. Great progress in the future is certain. But if you ask whether we may hope to reach at last a complete or final solution of the problem of heredity, I fear the answer must be, no. The man of science should be the first to admit that science can not attain to a complete understanding of anything. The explanation of any phenomenon only uncovers new phenomena behind it that still demand explanation, in endless succession; and such is the essential characteristic of scientific progress. Science does not aim at ultimate explanations; and could we find them, science would be emptied of its interest to the investigator.

EDMUND B. WILSON

COLUMBIA UNIVERSITY

### CHANCELLOR JORDAN AND PRESIDENT BRANNER

At the commencement of Leland Stanford Junior University on May 19 Dr. David Starr Jordan made a statement as follows:

I wish at this time to make a personal statement. In the interest of larger duties toward the university and toward the public, I have expressed to the board of trustees the wish to be relieved so far as may be from routine duties of the presidency.

In appreciation of this wish, and for the expressed purpose of allowing me "to represent more fully the university in its functions toward the public, and the relations of the university to educational agencies outside the university itself," the board of trustees at its meeting on May 23 will create the new office of chancellor of the university.

The position of president will be filled by Dr. John Casper Branner, my intimate friend for forty-three years, my academic colleague for twenty-nine years, and, as vice-president of the university for fifteen years, my closest administrative associate.

In accepting the chancellorship, and withdrawing from the immediate direction of administrative affairs, I shall abate no part of my interest in the university to which I have given the best years of my life, and to which I hope the best that remains will also be dedicated.

In placing the immediate control in the hands of one of the ablest of American scholars, one of the most successful of teachers and most loyal of men, I am sure that the board of trustees has made no mistake. So long as Dr. Branner shall direct its affairs the university will continue to develop the highest purposes of its founders, and of our colleagues, who, through twenty-two eventful years, have maintained and carried forward its standards and ideals.

Dr. J. M. Stillman then made the following statement:

With the consent of the president and at the request of members of the board of trustees, I am to speak a word of appreciation and welcome to President Jordan on assuming the new dignity of the chancellorship of the university.

The creation of this office has had two purposes: First—the division between the offices of chancellor and president of the burden of administrative duties and responsibilities hitherto vested solely in

the president, and which the development of the modern university has made increasingly laborious and onerous. Second—in high appreciation of the great service President Jordan has rendered and is rendering, not merely to this university, but to the world's work in the cause of education, science and civilization, it is intended that the institution of this new office shall, by thus relieving him of much of the routine of executive work, enable him to devote his attention in increasing measure to the greater problems within and without the university.

For twenty-two years President Jordan has been the inspiration of Stanford University. What it is is due mainly to his high ideals, his breadth of outlook and warmth of sympathy. These qualities and abilities the university needs in the future as in the past, and these the office of chancellor ensures us. Trustees and faculty, alumni and students, will continue to profit by his wisdom and his enthusiasms. But it is also recognized that the world at large has a claim upon his abilities which it should be the mission of Stanford to further and to encourage.

In the belief that the division of administrative functions between two such cooperative and sympathetic leaders as Chancellor Jordan and President Branner, will promote the efficiency, usefulness and influence of the university, and that under their joint guidance the aims and ideals of Stanford University will be carried forward to greater and grander development, I venture to assume that I express the sentiment of the whole university community in extending to Chancellor Jordan our congratulations upon his well-deserved and welcome respite from a large share of administrative detail, and upon his increased opportunities for the highest service not only to this university, but to the wider world beyond its gates.

### THE PENSION PLAN OF THE AMERICAN MUSEUM OF NATURAL HISTORY

For a long time the trustees of the American Museum of Natural History have had under consideration a plan for adequately providing for employees who were of mature age or who had been long in the service, and who through their efficiency and faithfulness were entitled to some recognition. A plan was finally worked out by a committee of trustees and a committee of employees and was adopted by the trustees at the annual meeting in Feb-

ruary. The plan went into effect on March 1, 1913.

The plan is similar to those in successful operation in many great manufacturing corporations in the United States. It is a contributory system, the subscribing employees contributing 3 per cent. of their salaries, and the trustees contributing an equal amount to the fund.

The plan already briefly noted in *SCIENCE* provides:

1. Pensions.—Six classes of pensions according to length of service and age, the pensions varying from 25 per cent. to 50 per cent. of the average salary of the last three years.

2. Health Insurance.—Gratuity to the employee in case he is totally disabled through illness, or his position is abolished.

3. Life Insurance.—A gratuity to a beneficiary, in the event of the death of the employee, and under certain conditions in the event of the death of a pensioner.

4. For the return of the employee's contribution with simple interest at 3 per cent. in case the employee leaves the service of the museum before he is eligible for a pension.

The plan also makes provision for exceptional cases; leave of absence without pay; absence from the service for a certain period; return to the service; reduction of present rate of contribution when feasible, and for the amendment or alteration of the plan as circumstances may warrant in the future.

#### SCIENTIFIC NOTES AND NEWS

At the annual meeting of the American Academy of Arts and Sciences held on May 14 last, it was voted to award the Rumford Premium to Professor Joel Stebbins, of the University of Illinois, for his development of the selenium photometer and its application to astronomical problems.

The gold medal of the Swiss Geographical Society will be presented to Admiral Peary at a banquet to be given at Geneva, on May 31.

DR. ALFRED H. BROOKS, of the U. S. Geological Survey, has been awarded the Conrad Maltebrun gold medal of the Paris Geographical Society.

IN appreciation of his services in reestablishing the American Rainbow trout in Germany, Dr. Hugh M. Smith, United States Commissioner of Fisheries, has been presented with a medal by the German Fishery Society.

DR. HENRY S. CARHART, emeritus professor of physics in the University of Michigan, and Professor F. R. Moulton, professor of astronomy in the University of Chicago, have been made honorary corresponding members of the British Association for the Advancement of Science.

PROFESSOR HERMANN VON VÖCHTING has been elected a foreign member of the Linnean Society, London.

DR. GISBERT KAPP, professor of electrical engineering in the University of Birmingham, has been appointed president of Section G (engineering) of the British Association for the meeting to be held in Birmingham in September next.

ANNOUNCEMENT is made at the University of Chicago of the joint award to Dr. George L. Kite and Mr. Esmond R. Long, graduate students in the department of pathology and bacteriology, of the Howard Taylor Ricketts prize of \$250 for original research in that department. The prize was established by the widow of Dr. Ricketts, who died in the City of Mexico from typhus fever contracted while studying the disease.

THE committee on medical research of the American Medical Association has awarded a grant of two hundred and fifty dollars to the department of bacteriology of the Hoagland Laboratory, Brooklyn, to defray the expenses of an investigation on the immunity reactions of edestin, a report of which is shortly to appear in the *Journal of Infectious Diseases*.

AMONG American astronomers who expect to attend the meeting of the International Solar Union to be held at Bonn, Germany, in August next, are Professors E. C. Pickering, Harvard College Observatory; Frank Schlesinger, Allegheny Observatory; J. A. Parkhurst, Yerkes Observatory; C. E. St. John,

Mount Wilson; H. N. Russell, Princeton, and J. S. Plaskett, Ottawa.

MR. EDWIN HATFIELD ANDERSON has been promoted to be director of the New York Public Library, succeeding the late Dr. John S. Billings.

C. S. RIDGWAY, assistant professor of botany at the Alabama Polytechnic Institute, Auburn, Ala., has resigned in order to accept an appointment in the Bureau of Plant Industry at Washington.

MR. LLOYD B. SMITH, professor of geology in the Carnegie Institute of Technology of Pittsburgh, Pa., has resigned to enter the employ of the Associated Geological Engineers in the examination of oil and gas properties.

DR. KARL GEISER, head of the department of political science in Oberlin College, will spend the summer in Germany investigating rural problems with special attention to rural local government.

A BIOLOGICAL expedition is being sent out by the University of the Philippines and the Bureau of Science. It started from Manila on April 5 for Taytay Bay on the northeastern coast of the Island of Palawan, and will remain in the field for two months. The party will consist of Dr. Merrill, chief of the division of botany of the Bureau of Science, Mr. Schultze, entomologist of the Bureau of Science; Mr. Rowley, instructor in geology, of the University of the Philippines; Messrs. Griffin, Cowles, Wharton, Day and Light, of the department of zoology of the university, and Mr. Barnes, teacher of zoology of the Bureau of Education. Including the assistants and laborers, the working party will consist of about twenty-five persons. The expedition will be under the direction of Professor Griffin. The region to which the party goes is entirely unexplored, but is said to be extremely rich in its fauna and flora.

AT the annual general meeting of the Institution of Civil Engineers, held in London on April 29, the result of the ballot for the election of officers was declared as follows: *President*, A. G. Lyster; *Vice-presidents*, B. H.

Blyth, J. Strain, G. R. Jebb, A. Ross; *other Members of Council*, J. A. F. Aspinall, J. A. Brodie, W. B. Bryan, Col. R. E. B. Crompton, C.B., J. M. Dobson, Sir H. F. Donaldson, K.C.B., E. B. Ellington, W. H. Ellis, W. Ferguson, Sir Maurice Mitzmaurice, C.M.G., Sir J. P. Griffith, Dr. C. A. Harrison, W. Hunter, H. E. Jones, Sir Thomas Matthews, Dr. W. H. Maw, C. L. Morgan, B. Mott, A. M. Tipplett, Sir Philip Watts, K.C.B., W. B. Worthington, Dr. Dugald Clerk, F.R.S., R. S. Highet, Dr. E. Hopkinson, F. Palmer and H. N. Ruttan.

THE special faculty committee from the University of Wisconsin appointed by President Charles R. Van Hise to receive and provide entertainment for the party of over 100 citizens of Pennsylvania, Maryland and Connecticut who spent the four days between May 21 and May 24, inclusive, inspecting the University of Wisconsin consisted of the following men: Professor L. E. Reber, dean of the Extension Division; Professor J. G. D. Mach, representing the College of Engineering; Frank Barron Morrison, representing the College of Agriculture; Professor Julius E. Olson, of the Scandinavian Department; Professor Ralph Starr Butler, of the Extension Division; W. H. Lighty, secretary of the Extension Division; Professor Dana C. Munro, head of the History Department; Professor George C. Comstock, head of the Astronomy Department; Dr. Hermon C. Bumpus, business manager of the university; Professor Scott H. Goodnight, of the German Department, and Professor E. A. Ross, head of the Department of Sociology.

PROFESSOR HENRY L. BOLLEY, head of the botany department at North Dakota Agricultural College, gave a public lecture at the College of Agriculture of the University of Wisconsin this week, in which he explained his theory for crop failure which results when cereal grains are planted in the same fields for several years. It was argued that the failure of the crop is not due to exhaustion of the soil fertility, but to the accumulation of soil parasites which are poisonous to the cereal grains.

PROFESSOR JULIUS STIEGLITZ, of the University of Chicago, lectured on May 21 at the University of Illinois on "Combustion, or the Electric Theory of Oxidation."

DR. FRANK SCHLESINGER, director of the Allegheny Observatory, delivered a lecture on "Astronomical Photography" before the Royal Astronomical Society of Canada, at Ottawa, on April 22 and at Toronto University on April 24.

THE Bakerian lecture of the Royal Society was delivered by Sir J. J. Thomson on May 22, the subject being "Rays of Positive Electricity."

THE first Wilbur Wright memorial lecture was delivered by Mr. Horace Darwin, F.R.S., at the Royal United Service Institution on May 21, under the auspices of the Aeronautical Society, which has raised a fund for the annual delivery of a lecture to commemorate the work of Wilbur Wright.

ADDISON BROWN, ex-judge of the United States Court, for many years a member of the New York Academy of Sciences, a fellow and a patron, died at his residence in New York City on April 9, 1913, in the eighty-fourth year of his age. Judge Brown's favorite studies were botany and horticulture, but he also took great interest in astronomy. He was a member and benefactor of the New York Botanical Garden, one of its original incorporators, and, at the time of his death, its president. The council of the New York Academy of Sciences has passed a resolution, drawn up by a committee consisting of N. L. Britton, J. J. Stevenson and E. O. Hovey, which reads as follows:

WHEREAS, The council of the New York Academy of Sciences has learned of the death of Ex-Judge Addison Brown, who for many years has been active in promoting the welfare of botany and its related sciences in this city,

*Resolved:* That the council appreciates his services to science, and mourns his loss; that the above memorial and preamble be entered on the minutes of the council and a copy be sent to his bereaved family.

DR. WILLIAM HALLOCK, professor of physics in Columbia University since 1892, known for

his researches in physics and for his interest in educational and scientific organization, died on May 20, aged fifty-six years.

DR. WILLIAM MCMURTRIE, one of the leading industrial chemists of the United States, formerly chief chemist of the Department of Agriculture and professor of chemistry in the University of Illinois, died on May 24, aged sixty-two years.

DR. ERNEST KITTL, director of the Royal Natural History Museum at Vienna, professor in the Vienna Institute of Technology, known for his contributions to geology, died on May 1, in his fifty-ninth year.

THE U. S. Civil Service Commission announces an examination for electro-metallurgist on June 18, 1913, to fill a vacancy in the Bureau of Mines, Department of the Interior, for service in the field, at a salary ranging from \$1,500 to \$1,800 a year.

THE Newcastle city council has decided to invite the British Association to meet in Newcastle in 1916.

THE Minister of the Interior of the Canadian government has authorized the purchase and installation of a reflecting telescope of not less than sixty inches aperture for the Dominion Observatory. The telescope will probably be erected at a suitable site in the Canadian Rockies.

THE legislature of California has passed a bill, drawn by Dr. Charles L. Edwards and introduced in the assembly by Mr. Frank H. Mouser, providing for a survey of the coastal waters preliminary to the establishment of a legally protected aquaculture. It is intended to divide the California coast into from three to five districts within which a considerable number of perpetual reservations will be formed for the natural and artificial propagation of animals and plants inhabiting the sea. The law will provide for leasing of sea farms and the patrol and protection of the coastal waters. The survey is placed under the Scripps Institute of Biological Research of which Dr. W. E. Ritter is director. A report is to be made to the governor on or before November 1, 1914.

THE United States Geological Survey had another close call on Sunday, May 18, in a destructive fire that practically gutted the basement of the entire building which it occupies. Owing to the congested condition of the store rooms and document rooms and to the escape of gas, the fire proved to be most stubborn and difficult to handle and resulted in the collapse of some 20 firemen, among them the chief of the Washington fire department. There was little flame, but the smoke poured in dense volumes from the Survey building, suffocating the firemen, who, however, fought desperately to keep the fire confined within the basement. The chief of the fire department states that had it got past the staircase which the men were holding and into the elevator shafts probably the entire building and possibly other adjacent buildings would have been consumed. The destruction, as it was, resulted in a loss of about \$75,000, mostly in topographic maps, geologic folios, and reports, which, however, can be replaced. The unpublished data and other material in the upper floors of the building, having an estimated value between four and a half and five million dollars, were fortunately unharmed. "The only thing that saved the rest of the survey building from total destruction," said Director Smith in an interview, "was the efficiency of the Washington fire department, aided as it was by some fire-proof doors leading from the basement to the upper hall, which had been erected on the recommendations of the chief of the fire department and the fire marshal. In its present quarters, after installing every possible safeguard, it appears that the government must rely upon the bravery and efficiency of the Washington fire department." The survey's campaign of last winter resulted in the authorization by congress of a new survey building to cost \$2,596,000, but work on it can not begin until the money is made available in the next appropriation bill. Then, according to the usual time required in the construction of government buildings, it will be from three to four years before the survey can get out of its present quarters.

As a result of the fire in the Geological Survey building the director has announced a "fire sale" of geologic folios. The entire basement, in which the folios were stored, was filled with dense smoke and many of the folios were burned, others scorched, and all more or less damaged by water. With the approval of Secretary Lane the director announces that he will sell the entire remaining stock of some 150,000 folios, four fifths of which are probably as near perfect as goods usually offered in a smoke or fire sale, at the nominal price of 5 cents each. The regular retail price of the standard folios is 25 cents, but a few unusually large folios have sold for 50 cents, and the regular price of the "field edition" of the later folios, a more convenient form for use in the field, is 50 cents. All these are now to be had at 5 cents each, but no wholesale rate applies. The stock includes probably 50,000 to 100,000 copies on which the real damage is practically negligible. Application should be made to the director, U. S. Geological Survey, Washington, D. C., and remittance made by money order or in coin. Lists will be sent on application.

AN exhibition by the Pennsylvania Forestry Association was held in Horticultural Hall, Philadelphia, May 19 to 24. The association had arranged to make this exhibition as comprehensive as possible and, to that end, had included specimens of various woods, barks, leaves, seeds and other indicative features, growing seedlings, forest animals, fish, birds and insects of Pennsylvania, uses of lumber, wood preservation, wood substitutes, utilization of waste forest products. Exhibits were received from: Pennsylvania Department of Forestry, Chestnut Tree Blight Commission, Pennsylvania Fish Protective Association, Lumberman's Exchange of the City of Philadelphia, Pennsylvania State College, Pennsylvania State Museum, University of Pennsylvania, U. S. Forest Service, and a number of important associations or corporations interested in forest preservation, lumber production, etc. A series of addresses (some liberally illustrated) was given by men prom-

inent in the field of forestry, in the afternoons and evenings of the week.

THE Wistar Institute in Philadelphia is remodeling a building  $90' \times 31'$ , three stories in height, to be used for an animal house. The first floor and basement are to be entirely of iron and concrete construction with rooms varying in temperature and light according to the requirements of the colony. The building will have space sufficient for 1,000 cages, and will be equipped with steam heat, electric lights and hot and cold water. A covered passageway will connect it with the present museum and laboratory building. The building will contain a balance room where accurate weights and measurements may be taken. The necessary apparatus for the preparation of food and a crematory for the disposition of waste material and the heating of water will be installed. The building will furnish more ample space for the work in progress and give opportunities for extending the experimental work with animals. The colonies of white rats and opossums will be transferred from the laboratory building and the farm in New Jersey to this building as soon as it is ready.

A HUNDRED new maps a year are the product of the big engraving and printing plant of the United States Geological Survey at Washington. About two atlas sheets a week are turned out in the construction of the great topographic map of the United States. The 15 new sheets added during the last six weeks to the 2,200 now carried in the regular stock show good examples of the widely different kinds of country covered by the government topographers. The areas mapped on these sheets range from the high forested mountain region of Colorado to the low, rich alluvial bottom lands of Mississippi and Louisiana—lands valuable for mineral resources, and lands rich in agricultural possibilities beyond the dreams of avarice. For any comprehensive development of these areas the topographic base map becomes the first engineering necessity. The scale of the maps varies from 1 inch on the paper, representing half a mile of country, with a contour interval of only 5 feet, for the Mississippi delta lands

—showing a very detailed survey suitable for a drainage base—to 1 inch representing 2 miles, with 100-foot contours, for the Castle Rock quadrangle, Colorado—covering an area which does not require such refined work. The Castle Rock area contains coal and lignite and a report on it will be made later by the survey in the form of a geologic folio; but the vicinity of Castle Rock is also famous for its potatoes, which are comparable to the famous Greeley potatoes, and for other agricultural products. The western portion of the area includes part of the Pike National Forest, and for national forest administration the map affords an ideal base. Three of the maps represent lands along Mississippi River in the Yazoo Delta; they show parts of the Moon Lake quadrangle, the Hollywood (Tunica County) quadrangle and the Lake Cormorant quadrangle, all in Mississippi. These maps were made in cooperation between the Federal Survey and the Tallahatchie Drainage Commission of the state of Mississippi. They are on the scale of 1 inch to half a mile, with 5-foot contour intervals, and show every slough and swampy place and every inequality of the area which must be taken into consideration in planning a drainage system that shall make these lands the most productive in the United States. Farther down the river, in Louisiana, similar areas have been mapped in cooperation between the Federal Survey and the Fifth Louisiana Levee District of the state of Louisiana, the sheets portraying portions of three quadrangles, the Ashton Bridge, Millikin and Millikens Bend—land built from the silt brought down by the great river and of nearly inexhaustible fertility. Another map of an area cut by the course of the Mississippi—the Milan quadrangle, Illinois—shows country of a different character. Here at Rock Island the Father of Waters is less of a problem. This map was made in cooperation between the Federal Survey and the state geologist of Illinois. The scale of this map is 1 mile to 1 inch and the contour interval 20 feet. A still different contour interval—50 feet—is that of the map showing the Salinas quadrangle, in Monterey County, California, where the work was done in coopera-

tion between the Federal Survey and the state of California.

We learn from *Nature* that it is proposed to celebrate the centenary of the foundation of the Indian Museum in Calcutta next February. Originally founded as a branch of the Asiatic Society of Bengal at the suggestion of Wallich, the botanist, on February 2, 1814, the Indian Museum became a government institution in 1867, after prolonged negotiations with the government of India, which accepted the society's collections to form the nucleus of an imperial museum in Calcutta. A centenary committee has been formed with Lord Carmichael, the governor of Bengal, as chairman, and Sir Asutosh Mookerjee, vice-chancellor of the Calcutta University, as vice-chairman. The committee has decided to publish an official history of the museum, to raise a special fund for the improvement of the public galleries, and to hold a reception in the museum on the anniversary of its foundation.

#### UNIVERSITY AND EDUCATIONAL NEWS

THE General Education Board at its May meeting made appropriations of \$837,600. Conditional appropriations for colleges are as follows:

John B. Stetson University, Deland, Fla.	\$ 50,000
Northwestern University, Evanston, Ill.	100,000
Pomona College, Claremont, Cal.	150,000
Union College, Schenectady, N. Y.	75,000
Williams College, Williamstown, Mass.	100,000
Appropriations for special purposes are as follows:	

For demonstration work in agriculture in the southern states, which include the boys' corn club work	180,050
For the promotion of girls' canning and poultry clubs throughout the south	75,000
For agricultural demonstration work in five counties of Maine	14,500
For the beginning of agricultural demonstration work in New Hampshire	7,500
For professors of secondary education in the several state universities of the southern states	30,550
For state supervisors of negro schools in several southern states	20,000
Schools for negro students in the south	35,000

A NEW chair of bacteriology is to be founded in Edinburgh University under a bequest from Mr. Robert Irvine, of Royston, Granton. *Nature* states that at his death, eleven years ago, Mr. Irvine bequeathed 230 shares of £10 each in a company for developing the resources of Christmas Island for the purpose of establishing the chair when the interest from the shares should reach £25,000 or £30,000. The accumulated dividends on these shares now reach more than £30,000. It is understood that £25,000 will go towards the maintenance of the professorship, and that the remaining £5,000 will be used in providing the class-rooms, laboratories and the necessary equipment.

DR. P. M. DAWSON, a graduate of Johns Hopkins University, and of its medical school, and for eleven years a member of its physiological staff, has been appointed instructor in physiology at the University of Wisconsin Medical School.

THE following promotions and new appointments have been made in the Stanford University Medical Department: Dr. Thomas Addis has been promoted to associate professor of medicine, Dr. E. C. Dickson and Dr. W. W. Boardman have been made assistant professors of medicine; Dr. Leo Eloesser and Dr. F. E. Blaisdell have been made assistant professors of surgery. Dr. R. G. Brodrick, of the San Francisco Board of Health, has been appointed assistant clinical professor of hygiene and public health. In the division of medicine Dr. W. F. Schaller has been made assistant clinical professor, assigned to neurology, and Dr. J. M. Wolfsohn, clinical instructor, assigned to neurology. Dr. A. A. O'Neill has been promoted to clinical instructor in medicine and Dr. G. A. Rothganger has been appointed instructor in surgery.

#### DISCUSSION AND CORRESPONDENCE

##### THE CALIFORNIA ACADEMY OF SCIENCES

THE California Academy of Sciences in San Francisco is an institution of about 400 cor-

porate members. The academy is endowed with property approximating a million dollars in value, with the income of which collections and expeditions are maintained, and curators and other scientific and administrative employees are engaged. The members elect annually a board of seven non-salaried trustees, who fix the salaries of employees and otherwise administer the business affairs of the institution; and a non-salaried council, consisting of the president, two vice-presidents, two secretaries, the treasurer, the librarian and the director of the museum of the academy. The council plans the scientific work of the academy, appoints the curators, and recommends their salaries to the trustees.

Leverett Mills Loomis became curator of ornithology in the academy June 12, 1894, and has held the position continuously since that time. At the annual election in January, 1902, he was elected director of the museum, and was reelected to this office each year until and including 1912. In December of 1912 the nominating committee of the academy, regularly selected by the council and trustees in joint meeting, presented for 1913 a ticket of officers the same as the incumbents during 1912, with the sole exception that another candidate was nominated for director of the museum in place of Mr. Loomis. Although there is constitutional provision for contesting elections, no such contest was made, and Mr. Loomis's tenure of the directorship thereby came to an end with 1912.

During January and the first half of February, 1913, the council reappointed—and the trustees subsequently voted salaries for—all curators and assistants who had served during 1912, excepting Mr. Loomis, who was not reappointed as curator of ornithology.

At the stated meeting of the academy, that is to say, of the corporate members, on February 17, 1913, notice was given that the following resolution would be offered at the next stated meeting, and notice thereof was ordered sent to all members:

That the academy regrets the action of the council in not recommending to the trustees the

appointment of L. M. Loomis as curator of ornithology, for the year 1913. Mr. Loomis has held this office for more than eighteen years, has twice built up a unique collection of birds for the academy, and his integrity, scientific competence and executive ability are unquestioned. The directorship of the museum is an elective office; the executive curatorship of the academy, though appointive, is an adjunct to the directorship, and may therefore justifiably go with it; but the curatorship of ornithology, like all other departmental curatorships, should be bestowed and reawarded only on the basis of merit and service. The failure to reappoint Mr. Loomis would therefore be a breach of fairness on a point of policy in which all reputable scientific institutions are in accord. It could be construed only as the intrusion of personal jealousies or political enmities into the field of scientific service, and would accordingly bring the academy into bad repute as to its equity in dealing with scientific employees. The academy therefore earnestly requests its council to appoint Mr. Loomis curator of ornithology for 1913, and urges upon its trustees to engage Mr. Loomis to take charge of the department which he has so long, so faithfully and so successfully administered, at the salary which it has been and is the practise to pay to academy curators giving full time to their duties.

At the stated meeting of March 3 a substitute for this resolution was offered by the original proponent, and adopted as follows by the academy:

As the council at recent meetings has failed to recommend the reappointment of L. M. Loomis to the curatorship of ornithology, and as it seems that said action could not have been made with all bearings of the question in mind, the academy herewith respectfully requests the council to appoint Mr. Loomis curator of the department of ornithology, and urges upon its trustees to engage him to take charge of this department, at the salary which is customarily paid by the academy to curators giving full time, with the following considerations in view: the long service of Mr. Loomis as a curator in the academy; the success achieved by him in accumulating large and valuable collections of birds; and the moral basis of the relation of an institution to employees of long standing.

At the next stated meeting of the academy, on March 17, 1913, the following communication from the council was read:

SAN FRANCISCO, CAL.,

March 17, 1913.

TO THE MEMBERS OF THE CALIFORNIA ACADEMY  
OF SCIENCES:

Having been officially notified of your request as adopted by resolution at the stated meeting of the academy on March 3, that Mr. L. M. Loomis be re-appointed curator of the department of ornithology at the compensation which is customary for curators devoting full time to the affairs of their departments, your council desires to assure you that this request is receiving their earnest and most serious consideration.

For the council,

C. E. GRUNSKY,  
*President*

J. W. HOBSON,  
*Secretary*

At the stated meeting of April 7 the council reported to the academy that it had adopted the following resolution:

Having under consideration the request of the academy that the council reappoint Mr. Loomis curator of the department of ornithology for the current year, be it

*Resolved*, that it is the sense of the council that such reappointment would not be for the best interests of the academy.

Upon presentation of this report from the council, the following resolution was moved and was adopted by the academy:

The academy condemns and disavows the refusal of its council to reappoint L. M. Loomis curator of ornithology, without any charge having been brought against him after eighteen years of faithful and efficient service, as an act of unfairness, and as bringing reproach on the name and equity of the academy.

A. L. KROEBER

#### UNIVERSITY LIFE IN IDAHO

TO THE EDITOR OF SCIENCE: In reply to Professor Kellogg's letter in the issue of SCIENCE, May 16, 1913, regarding the reported dismissal of Professor Aldrich, of the University of Idaho, I may say that I have not made any recommendation regarding Professor Aldrich's tenure of office to the board of regents, nor to any member of the board—nor have I been asked to do so. I am informed that the action

of the board was undertaken on its own responsibility and in fulfilment of its public trust, and the action was confirmed by the new board of education organized for all of the educational institutions of Idaho. I had no part in either proceeding. Accordingly, I am not entitled to share in either the credit or the criticism of the result. The rest of Professor Kellogg's letter is likewise unsupported in fact.

JAMES A. MACLEAN,

*President, University of Manitoba*

#### THE COTTRELL PROCESS FOR DEPOSITING DUST AND SMOKE

MR. LINN BRADLEY, of the Research Corporation, recently gave a lecture on the Cottrell Process<sup>1</sup> before the Lehigh Valley Section of the American Chemical Society. It was my privilege to help Mr. Bradley in his experimental demonstration of the process, and I suggested to Mr. Bradley a modification which proved to be very satisfactory for the lecture table.

A glass tube two inches in diameter and four or five feet long is supported in a horizontal position with a heavy wire or metal rod lying along the bottom of the tube and connected to one terminal of a small Holtz machine. A very fine wire is stretched through the tube and supported on two glass columns beyond the ends of the tube, and this fine wire is connected to the other terminal of the electric machine. The best procedure is to keep the machine running continuously with its terminals short-circuited. Then the tube is filled with any kind of smoke, the short circuit is quickly removed, and the smoke is seen to be deposited very quickly indeed.

Those who are not familiar with the process may be interested to know the action which takes place, which is as follows: The voltage between the fine wire and the heavy wire or rod is sufficient to cause a continuous corona

<sup>1</sup>The Cottrell process has been placed in the hands of the Research Corporation of New York City; any proceeds which may come from the practical use of the process are to go to the Smithsonian Institution of Washington.

discharge from the fine wire. In this corona discharge the air molecules are dissociated into ions and these charged ions quickly attach themselves to the particles of dust or tar. The intense electric field between the two electrodes then drags the particles of dust or tar to the large electrode, where they are deposited.

W. S. FRANKLIN

#### A LOCAL MAGNETIC STORM

IN SCIENCE, of March 21, reference is made to a paper just published by the Academy of Science of St. Louis with the above title. In this paper evidence is presented to show that atmospheric ions tend to set like magnets along the lines of the earth's magnetic field. The effect of gusts of wind in disturbing these ions, and in thus producing continual swaying of the lines of force due to variations in permeability, is pointed out.

A more local and somewhat similar magnetic storm may be artificially produced as follows:

Suspend a needle on a silk fiber. Provide it with a mirror, telescope and scale. Partially compensate the effect of the earth's field by bar magnets set in parallel position. Place two bar magnets on opposite sides of the needle, as in the Gaussian method of deflection. Place a plate of glass over one magnet, and sprinkle iron filings upon it. The deflecting effect of that magnet is increased. The needle no longer lies in the magnetic meridian. Balance the effect on the needle by adjustment of the other deflecting magnet and tap the plate. The permeability of the space around the magnet is again increased. A new readjustment may be made. Disturb the iron filings by means of a brush, applied to any small area of the plate. A magnetic storm is thus produced. If the filings were free to move without friction, they would all respond to the disturbance. The needle does respond. If the filings are made to accumulate near the poles, the deflecting effect of the magnet is greatly increased. If the magnet is supported at its middle part so that it is

lifted above the plate of glass, the poles may be loaded with iron filings. The apparent magnetic moment of the bar may thus be increased about 8 or 10 per cent. Such a magnetic storm as is thus produced in the surrounding space appears to be similar to that produced in the field of the earth, when atmospheric ions accumulate around the magnetic poles of the earth. If any of these Faraday lines are disturbed, they are all disturbed. The balanced needle tells the story.

It seems very probable that the daily variations in the earth's field may be explained as due to this change in permeability brought about by ionization of the air by sunlight. The lines of force sway in opposite directions during the forenoon and afternoon of each day, their lateral motion being greatest in the equatorial belt. There is also apparently a similar swaying in a vertical direction.

In the forenoon the north end of the needle swings towards the west in the northern hemisphere, while the south pole swings towards the west in the southern. In the equatorial belt the needle suffers no change. These daily variations are modified by summer and winter conditions, as they should be if the above explanation is valid.

FRANCIS E. NIPHER

#### PLUS AND MINUS

IN a review of my book, "On the Foundation and Technic of Arithmetic," in SCIENCE, April 18, 1913, Professor Cajori, after quoting a sentence, says:

In view of the fact that historians have been in doubt as to the exact origin of + and —, the authority for Halsted's categorical statement would be interesting.

Hoping the readers of SCIENCE may be of the professor's mind, I venture an outline.

Minus, as the oral rendering of the symbol —, takes a sense which did not exist in Latin of any period. Murray says it probably originated in the commercial language of the middle ages. In Germany the Latin words *plus* and *minus* were used by merchants to mark an excess or deficiency in weight or measure. The earliest known examples of the

modern sense of *minus* are German. In the *Bamberger Rechenbuch* (1483) the tare to be deducted from the weight of a package is called *das Minus*. An Italian writer of the fourteenth century used *meno* to indicate the subtraction of a number to which it was prefixed. The symbol itself, —, De Morgan, most sound and erudite of mathematicians, says arose as a merchant's mark. Its adoption was helped by its likeness to the *obelus* used by ancient critics to indicate that a passage should be removed from the text. This obelus or obelisk was a straight horizontal stroke, either simple (—), or with a dot above and one below (÷), and in Denmark the sign ÷ is used for *minus*.

English examples of *plus* do not occur so early as those of *minus*; e. g., 1481-90 *Howard Househ. Bks.* (Roxb.) 417, v. yerdys, mynys the nayle, welwet blake. Cajori says Eneström shows "that with Widman + meant simply 'und' (and)," but how can this be brought to tally with the fact that Widman explicitly directs that the signs — and + be read *minus* and *mer* (mehr)? He uses them as signs already well known in his "Behende und hübsche Rechnung auf allen Kauffmannschafft" (1489); "was — ist, das ist minus, und das + ist das mer."

The adoption of the form + would be greatly helped by its likeness to a form of &=et, and Widman seems to have used the long preexistent form + in the two senses, *mehr* and *et*.

GEORGE BRUCE HALSTED

#### SCIENTIFIC BOOKS

*Schutzfermente des tierischen Organismus. Ein Beitrag zur Kenntnis der Abwehrmassregeln des tierischen Organismus gegen Körper-, blut- und zellfremde Stoffe.* By EMIL ABDERHALDEN. Berlin, Julius Springer. Eight text figures; pp. xi + 110. Paper cover, 3.20 M.; bound, 3.80 M.

In this little pamphlet Abderhalden gives an interesting survey of a method which the living organism employs to protect itself from the effects of foreign soluble substances which have entered its circulating juices. Under

normal conditions, for example, proteids do not reach the tissue cells in their native state, but only as fragments. This degradation of proteids is normally accomplished by the ferments of the gastro-intestinal canal, and some of the degradation products, after absorption, are then synthesized by the tissues into its own characteristic proteid. Native foreign proteids in the circulation are useless and often directly harmful to the tissue cells. However, when this contingency occurs experimentally or through disease, the invaded body is not entirely helpless, but digestive ferments are formed in the circulation, possibly from the leucocytes, which attack the foreign proteid and digest it. These protective ferments are formed very swiftly and have been demonstrated by Abderhalden in the plasma or serum twenty-four hours after the subcutaneous injection of the foreign proteid, while the plasma or serum of normal, non-injected individuals shows no trace of this ferment.

Similar results were obtained by Abderhalden when carbohydrates were injected, or when fats were driven unchanged into the blood by forced feeding. Here again he was able to show the presence of ferments in the blood which were able to split the foreign substance.

These facts were established by Abderhalden and his pupils largely through the use of the polariscope. When optically active or racemic substances are split by ferment action, the optical activity of the mixture changes and this change shows, in the first place, that a decomposition has occurred; in the second place, the character of the change may show what substances have been formed, provided that the chemical structure of the original substance used is accurately known, which is the case with many of the optically active polypeptids.

The facts briefly mentioned above have received an important application in the diagnosis of pregnancy. The circulation of the pregnant organism contains cells from the chorionic villi, and the maternal body reacts to these cells by forming peptolytic enzymes

not present in the non-pregnant individual. If now the serum or plasma of a pregnant woman is added to peptone prepared from human placental tissue and the mixture observed by the optical method, the initial rotation changes, while with serum from a non-pregnant woman, the initial rotation remains unaltered. As this phenomenon could be detected as early as the first month of pregnancy, the procedure promises to be of great value in the differential diagnosis between extra-uterine pregnancy and tumors of the adnexa. It may, perhaps, be added that this ingenious method apparently does not remove all the difficulties and doubts which surround the early diagnosis of pregnancy, for recent investigations seem to show that a positive reaction may also be obtained under other conditions than pregnancy.

The booklet may be recommended as a very readable, stimulating summary of a large number of investigations by Abderhalden and his pupils.

J. AUER

ROCKEFELLER INSTITUTE

*Methods for Sugar Analysis and Allied Determinations.* By ARTHUR GIVEN, B.S. Philadelphia, P. Blakiston's Son & Co. 1912. Pp. 75. Price \$2.00 net.

According to the preface, this book has been made, because, as the result of ten years' experience, the author has found that "it has become increasingly evident that the present methods as given in many of the books on sugar analysis and in the A. O. A. C. methods are not sufficiently explicit as to the proper method for a particular case, thereby confusing the novice, and making it difficult to secure uniform results. . . ."

The methods presented by the author are those which he, "from long practise on a very large variety of substances, considers to be best adapted for the purposes in hand."

In its limited range of seventy-five pages the book endeavors to cover the analysis of sugar-cane, cane-sugar and beet-sugar and their derived products, maple-sugar and maple-syrup, honey, commercial glucose, dextrin,

starch, condensed milk, milk chocolate, etc. A few tables and illustrations are scattered through the text.

There is undoubtedly room on the shelf of many an analyst for a work which shall give tested and tried methods for the analysis of sugar and allied, saccharine, products. The author has brought together some material of value for this purpose; there is however—in spite of his conviction—room for considerable doubt as to whether his choice of methods would always commend itself to the approval of other experienced analysts.

In discussing the determination of sucrose in raw sugars, the use of Wiley's correction factor is recommended to obtain "the true polarization in sugars polarizing over 90°" if the temperature of polarization varies from 20° C., and then the author goes on to state that such correction is not applicable "where the reducing sugars exceed 3 per cent., as differences in temperature affect the reducing sugars more strongly than sucrose."

It would be interesting to learn why and how this arbitrary limitation of 3 per cent. has been decided upon by the author, and how he would obviate the disturbing influence of the precipitate-error in clarification which tends to offset the reduction in the specific rotatory power of sucrose caused by an elevation of temperature above the temperature at which the polariscope has been graduated.

The concise, not to say terse, manner of expression employed in the book is a good feature, yet a few additional words of explanation would not have been out of place in several instances, for example in giving the formula to be used in the Clerget method (p. 11). The novel way of printing the names of several of the more common sugars (p. 36) is apt to introduce more confusion in this already troublesome issue and the data given in that table are not always correct—thus, f. i. raffinose is hydrolyzed by invertase into d-fructose and melibiose, and not into d-glucose and d-galactose, as stated. Hydrolyzation of raffinose into d-galactose and sucrose is effected by emulsin.

F. G. WIECHMANN

*Principles of Economic Zoology.* By L. S. DAUGHERTY, M.S., Ph.D., Professor of Zoology, State Normal School, Kirksville, Mo., and M. C. DAUGHERTY, Kirksville, Mo. Philadelphia and London: W. B. Saunders Company. 1912. Cloth, 12mo. Pp. 410. 301 illustrations. \$2.00 net.

This recent text-book presents a number of commendable features and adds another to the rather numerous list of available text-books for the beginner in zoology. It seems more particularly adapted for the normal school work in which the authors are engaged, and this perhaps accounts for the effort to include a very large number of examples rather than to give a more detailed and exact description of representative forms in the principal groups of animals. Possibly the great number of forms mentioned would be confusing, but in the hands of a skillful teacher the book could certainly be very useful in the extending of acquaintance with animal forms in general. The economic feature of the work, which has been emphasized in its title, will make it welcome in many schools where attention to this phase of the subject is desired. While these references are usually brief they generally sum up in fairly compact form the more important economic points, and are quite suggestive for references to more extended works in this field.

The illustrations are numerous, usually well selected and very well printed, and add a very important feature to the book.

One point which seems somewhat of a blemish is the inclusion of a discussion of economic or other matter referring to an entirely different class under a sub-heading which is restricted to some minor division of the group, for example pages 40, 44 and 70, the discussion of economic importance included in a paragraph under minor classes in the branch, relate for the most part to species included in entirely different classes and without especial attention of the student might very likely be supposed to refer to the class in which the paragraph occurs. This fault is one which might easily be corrected by a different arrangement of sub-headings.

The substance in general seems to be carefully stated and while there are some errors, due no doubt to lack of first-hand knowledge, the preparation shows care, and while stated to be essentially a compilation, the authors are to be commended for the success shown in selection and presentation of material.

In typographical respects the book is very satisfactory and a credit to the publishers.

HERBERT OSBORN

#### THE MINERAL WEALTH OF CANADA

ALTHOUGH the discussion of reciprocity with Canada is now quiescent, yet all citizens of the United States are naturally interested in the development of our sister country. This is especially true of the readers of SCIENCE, because Canada has given to this country such a large number of eminent, influential and successful educators and scientists.

A recent publication of the Canadian Department of Mines gives us many items relating to the mineral wealth and to some of the resulting manufactures that ought to be of importance to our own people. This work is entitled "A General Summary of the Mineral Production of Canada during the Calendar Year 1911," by John McLeish, B.A., chief of the Division of Mineral Resources and Statistics.

From this we learn that the total value of the mineral products of Canada in 1911 was \$103,220,994, or \$14.42 per capita. The production was distributed amongst the various Canadian provinces arranged in order of the values as follows: Ontario, \$42,796,162; British Columbia, \$21,299,305; Nova Scotia, \$15,409,397; Quebec, \$9,304,717; Alberta, \$6,662,673; Yukon, \$4,707,432; Manitoba, \$1,791,772; Saskatchewan, \$636,706; and New Brunswick, \$612,830.

Of these mineral products the metallic were valued at \$46,105,423; the non-metallic at \$57,115,571, of which \$22,709,611 were for structural materials and clay products.

As a matter of comparison it is here pointed out that for the same year 1911 the mineral products of the United States, according to our

National Geological Survey, amounted to \$1,918,326,253, of which \$672,179,600 were for metallic and \$1,245,896,653 were for non-metallic, with a value of \$250,000 for materials not differentiated.

The table here given shows the relative values of some of the important mineral products common to Canada and this country. In those given Canada surpasses the United States in the value of its products only in nickel; but a few decades will doubtless see a great change in the relative values of the arsenic, asbestos (chrysotile), corundum and products of the two countries.

Metallic	Canada Value	United States Value
Pig iron .....	\$12,307,125	\$327,334,624
Silver .....	17,355,272	32,615,700
Gold .....	9,781,077	96,890,000
Copper .....	6,886,998	137,154,092
Lead .....	827,717	36,553,320
Zinc .....	101,072	30,964,794
Nickel .....	10,229,623	127,000
Non-metallic		
Coal .....	26,467,646	626,366,876
Natural gas .....	1,917,678	74,127,534
Petroleum .....	357,073	134,044,752
Peat .....	3,817	272,114
Clay products .....	8,359,933	162,236,181
Cement .....	7,644,537	66,705,136
Gypsum .....	993,394	6,462,035
Lime .....	1,517,599	13,689,054
Sand-lime-brick .....	442,427	897,664
Slate .....	8,248	5,728,019
Stone .....	4,428,757	77,108,567
Corundum and emery ..	161,873	6,778
Grindstones .....	52,942	907,316
Arsenious oxide .....	76,237	73,408
Phosphate rock .....	5,206	11,900,693
Pyrite .....	365,820	1,164,871
Asbestos .....	2,922,062	119,935
Mica .....	128,677	355,704
Mineral waters .....	223,758	6,837,888
Graphite .....	69,576	288,465
Salt .....	443,004	8,345,692
Talc .....	22,100	1,646,018

The mineral statistics were first collected for Canada in 1886, in which year the total value was \$10,221,255, since which time the values have in general increased up to 1910, when they were \$106,823,623 or the maximum.

The falling off in 1911 is attributed to the prolonged strike of the coal miners in the Province of Alberta and the Crownsnest district of British Columbia, as the resulting scarcity of coal and coke in those provinces seriously interfered with the smelting operations.

A matter of practical value to the United States is the question of the mineral exports and imports of the Canadian provinces. The total value of the exports of mine products and the manufactures thereof was \$52,546,593, of which \$11,424,905 was for manufactures. Nearly all of the Canadian copper, nickel and silver are exported, as are a large part of the gold, asbestos and mica. The manufactures of mine products exported are chiefly iron and steel goods, aluminum, calcium carbide, lime, acetate of lime and coke. Of the exports \$33,129,505 were sent into the United States; to the United Kingdom \$6,726,015; while the next largest amount was to Newfoundland and Labrador, \$580,632.

The imports into Canada of mineral products, chiefly in a manufactured or semi-manufactured condition, were in 1911 valued at \$181,839,077. Of these imports iron and steel and the manufactures thereof amounted to \$93,000,000; coal, ores, diamonds (unset) and bort, asphaltum, alumina, clays, etc., equaled \$48,000,000; copper, gold, silver, lead, platinum, tin and zinc reached \$18,750,000; while petroleum and clay products exceeded \$11,000,000.

In view of the above facts the following excerpt from the report is of interest:

The great excess of imports over exports would seem to indicate the existence of large opportunities for the development not only of Canada's mineral production, but also of many manufacturing industries which utilize mine products as raw materials. The fact, however, must not be overlooked that the geographical situation of Canada and the United States, separated by an imaginary barrier 3,000 miles in length, evidently results, notwithstanding the tariffs on both sides, in a mutually advantageous interchange of trade. Then we find large exports as well as imports of coal and of agricultural implements. The con-

tinued large export of crude unrefined ores and metal products and the corresponding imports of refined and manufactured metal products still point to opportunities for the development of metallurgical industries as well as industries for the treatment, refinement and manufacture of non-metallic products.

Owing to our contiguity, our mutual relations, our essential unity of race and general characteristics and identity of language, we can but wish our northern brethren success in the development of their rich mineral country.

AFTER the preceding remarks relating to this subject were in type, but not yet published, a recent "Preliminary Report on the Mineral Production of Canada during the Calendar Year 1912, prepared by John McLeish, B.A.," has been received, although the data are subject to revision for a final report.

The total mineral production is stated for 1912 to be \$133,127,489, or \$29,906,495 over that of the preceding year, and \$26,303,866 over that of 1910, heretofore the banner year. So notable an increase points towards a more general prosperity. The relative rank in production of the different provinces remains as in 1911, except that Alberta and Quebec have changed places, the product of the former being valued at \$12,110,960 and the latter \$11,675,682. For Ontario the value is \$51,023,134, for British Columbia \$29,555,323, and for Nova Scotia \$18,843,324.

Of the value of the total production, as is quite general, the non-metallic is the greater or \$71,949,500, while the metallic is \$61,177,989.

The value of some of the more important Canadian mineral products are given in the table below.

	Value
Coal .....	\$36,349,299
Silver .....	19,425,656
Pig iron .....	14,550,999
Nickel .....	13,452,463
Copper .....	12,709,311
Gold .....	12,559,443
Clay products .....	9,343,321
Cement .....	9,083,216

Stone .....	4,675,851
Asbestos and asbestic .....	2,979,384
Natural gas .....	2,311,126
Lime .....	1,717,771
Lead .....	1,597,554
Gypsum .....	1,320,883

The production of petroleum has been steadily falling off for the past five years, the value for 1912 being \$345,050. The values of the production of copper, silver and gold have increased, especially in the case of gold from the Porcupine District. In brief it may be said that except for petroleum, the values of all the Canadian productions have increased since 1911.

For 1912 the value of the exports of mine products and of the manufactures of mine products has been \$68,585,286, the chief ones being in order of value: silver, gold, copper, coal, nickel, asbestos, automobiles and aluminum.

By comparing the reports of previous years the mineral industries of Canada present, on the whole, very encouraging features for our northern neighbors and prove that a rapid development is taking place.

### SPECIAL ARTICLES

#### ARTIFICIAL PARTHENOGENESIS IN FUCUS

THE occurrence of natural parthenogenesis or the development of the gametes without fertilization has been reported for several forms among the Phaeophyceæ. Berthold and Oltmanns observed it in *Ectocarpus siliculosus*, which possesses, besides zoospores, gametes of two sizes. Both male and female gametes even in the same culture under certain conditions develop parthenogenetically. The question has been raised whether the so-called zoospores are not parthenogenetic gametes. Sauvageau observed that in *Giffordia secunda* antheridia were produced in greater numbers in July, but that none were formed in August or later, while numerous oogonia appeared at this season, many of whose

eggs cleaved very slowly without fertilization. The older observations of Thuret and of Crouan that the eggs of *Cutleria* develop without fertilization have been confirmed by Church, who reports that on the English coast *Cutleria multifida* develops mostly parthenogenetically, female plants being hard to find in August, and that scarcely any occur in the latter part of the season, the eggs developing without fertilization. As was previously observed by Thuret and Bornet, Williams has more recently found that the unfertilized eggs of *Dictyota* and of *Haliseris* segment a few times and then die.

It is evident that the Phaeophyceae show a strong tendency toward parthenogenetic development and that natural parthenogenesis may play an important part in the life history of several species. None of the Fucaceae, however, have been reported as being able to develop without fertilization, although Thuret mentions that unfertilized eggs of *Fucus* kept for several days become pear-shaped and that a cellulose wall is sometimes present. Thuret's observations have not been supported by Farmer and Williams, who have never been able to observe cellulose walls around unfertilized eggs. My own observations are in harmony with those of Farmer and Williams. While working at the Marine Biological Laboratory at Woods Hole, the past summer, it seemed worth while to apply to *Fucus* eggs some of the well-known experimental methods used by Loeb, Winkler, Delage, Lillie and others, whereby unfertilized eggs of certain invertebrates have been made to segment under the influence of artificial physical and chemical stimuli.

*Fucus vesiculosus*, a dioecious species, occurs near the shores between tide marks at Woods Hole, and plants, both in the vegetative and reproductive conditions, are usually abundant. The spermatozooids and oospheres are usually discharged sparingly during ebb tide and abundantly during flood tide. Plants were collected during ebb tide, the distal portions removed and placed in dishes on ice over night. Care was taken that the conceptacles

bearing eggs and sperms were kept separate. When it was desired to obtain the eggs and sperms, dishes containing conceptacles were filled with fresh sea-water, or after first exposing the conceptacles to a hypotonic sea-water, when eggs and sperms were discharged in large numbers. The freshly extruded eggs drop to the bottom of the dishes and can be taken up with a pipette and transferred to watch glasses for experiment. After a short time the eggs show a tendency to adhere very firmly to the bottom of the watch glasses so that fluids can easily be poured off and others added without losing the eggs.

The process of fertilization in *Fucus* has often been studied, and the details of development were especially studied by Thuret and later by Oltmanns. If the mature eggs and sperms are mixed together in the same dish in sea-water, the sperms collect in great numbers about the egg, and attaching themselves to the periphery cause the eggs to rotate rapidly by lashing the water with the cilia. Soon the eggs lose the power of attracting the sperms. They cease their rotation and settle down. Such eggs are fertilized. Farmer and Williams have shown that within five minutes after mixing the sexual cells the sperms have entered many eggs and within ten minutes the sexual nuclei fuse. Soon after fertilization a delicate membrane or cell wall is formed about the periphery of the oospore. As noted by Farmer and Williams, the character of the cytoplasm changes markedly, tending to assume a definitely radiating character, the lines radiating from the nucleus as a center. The oospores rest for about twenty-four hours, during which time there is a rapid increase in the thickness of the cell-wall and a further change occurs in the structure of the cytoplasm like those described by Farmer and Williams. At the periphery of the fertilized egg, just below the wall, the cytoplasm shows a definite alveolar structure.

After some time many of the oospores assume a pear-shaped form and by the next day all have divided. The first division, as has been observed by Rosenvinge and others, is at

right angles to the direction of the light. In the main my observations on the physiology of germination are in accord with those of Farmer and Williams. In watch glasses, placed on a laboratory table, the first division is usually at right angles to the bottom of the watch glass and at right angles to the direction of the light. Abnormalities in cleavage and development as described by Küster were sometimes, but seldom, observed. The cell away from the light is the rhizoidal cell, while from the other cell the young thallus develops. The subsequent cell divisions and growth of the plantlets in watch glasses follow the descriptions of Thuret and of Oltmanns and need no special mention. In watch glasses placed in larger dishes of sea-water, young plants of about 25 cells were grown in the laboratory. No attempt was made to rear the plants beyond these young stages.

In plants used to induce cell division by artificial means great care was taken to prevent contamination by sperms. The female plants were carefully washed with fresh water to kill any sperms which might adhere to them. None of the eggs obtained from such sterilized plants ever developed in the numerous controls, which were run in connection with the experiments, showing beyond a doubt that the female plants treated were absolutely sterile.

Loeb has shown that, when unfertilized eggs of the sea-urchin are placed for one and one-half to two minutes in a mixture of 50 c.c. of sea-water + 3 c.c. of 0.1 *m* acetic, butyric or other fatty acid and then transferred to normal sea-water, a fertilization membrane is formed. This method was applied to unfertilized *Fucus* eggs. In experimenting with the eggs those used at any one time were always divided into three lots. One lot was used as a control, another was fertilized and the third was treated with the solution. If a single egg in the control formed a cell-wall, which seldom happened, the three lots were discarded. In case the eggs were treated with acetic or butyric acid, as above described, a large number of them formed in about ten

minutes a membrane or cell-wall which was exactly similar to the one formed about normally fertilized eggs. By plasmolyzing the eggs the membrane is readily seen. Eggs not treated with a solution or not fertilized undergo cytolysis and degenerate. In any case many of the eggs failed to develop, but about one fourth as many formed membranes under the influence of the solutions as were formed about fertilized eggs. After the formation of the membranes if the eggs are placed in hypertonic sea-water, 8 c.c.-10 c.c. of 2.5 *m* NaCl or KCl + 50 c.c., sea-water for 30 minutes and are then brought back into normal sea-water, development continues. Nearly all of the eggs which have formed a membrane become pear-shaped, showing a rhizoidal papilla, and by next morning have cleaved. The rhizoidal cell is cut off and one or more cleavages have taken place in the other portion of the sporeling. If the cultures are properly aerated, sporelings develop resembling in every respect those grown from fertilized eggs. In place of sea-water containing a fatty acid, solutions of various other cytolytic substances were used, but none stimulated membrane formation or development as well as the acids.

With regard to the first formation of the cell-wall over the surface of isolated masses of plant protoplasm, it is usually attributed to a process of secretion by the outer layer. That the process is a rapid one is shown by the fact that in *Fucus* eggs a cell-wall is formed in ten minutes after the entrance of the sperm. Cell-wall formation may also be artificially induced, as shown above, by various substances. In some cases a cell-wall may appear under certain conditions on the surface of plasmolysed protoplasts in fifteen minutes, as has been shown by Klebs, Palla and others, while in other cases hours are required for wall formation. It would appear that the action of the acids in inducing a cell-wall to be formed about the unfertilized *Fucus* eggs is similar to the action which calls forth membrane formation in the animal egg. Considerable evidence exists indicating that the essential con-

dition for the formation of the fertilization membrane in many animal eggs is an increased permeability of the plasma membrane for substances which pass out and harden in contact with the sea-water. The rôle of the acid, etc., in membrane formation is held by many to be the increasing of the permeability of the plasma membrane of the egg.

That the first effect of the sperm of the Fucaceæ upon the egg is to cause cell-wall formation, conditioned as it seems to me by a momentarily increased permeability of the plasma membrane just as in certain animal eggs, is apparent from the observations of several investigators. Farmer and Williams furnish remarkable evidence showing that the entrance of the sperm supplies the stimulus which leads to the formation of the cell-wall in *Halidrys*. In this form pieces of the oospheres are sometimes pinched off during extrusion. These observers note that such pieces sometimes attract the sperms and become fertilized, surrounding themselves with a cell-wall in the normal way. The cases of merogony induced by Winkler in *Cystosira barbata* may, I think, be explained by assuming that the sperms increase the permeability of the non-nucleated fragments, as well as being the underlying cause of further development. In the normally fertilized eggs of *Halidrys* Farmer and Williams note that the entrance of the sperm causes the eggs to swell and become more transparent. In some cases movements of vacuoles are discernible and the nucleus may change its position. They conclude that these alterations ensue as a definite result of the stimulus given by the sperm. The fertilized egg becomes covered by conical projections, from each of which a fine thread projects, consisting of a series of droplets. After 3-5 minutes the fertilized egg resumes its spherical shape and decreases in diameter. They also observed that the sperms were repelled from fertilized eggs and conclude that this is due to the excretion of some substance which exerts a negative chemotactic and injurious effect on the sperms. Such eggs at once become invested in cell-walls, while

others not exhibiting these phenomena after a time degenerate.

The results of my experiments, in which cell-wall formation and subsequent development were induced in unfertilized eggs of *Fucus*, and the data mentioned above, seem to show that the first effect produced by the sperm upon the egg is purely superficial, causing an increase in the permeability of the plasma membrane. These conclusions are in harmony with those of certain animal physiologists. Therefore, theoretical considerations as to the causes of the change in permeability and the stimulus to further development need not be discussed here.

As yet I have been unable to investigate the nuclear behavior of the parthenogenetic plants of *Fucus*. Farmer and Williams, agreeing with Strasburger, hold that the *Fucus* plant contains the diploid number of chromosomes and that the reduction to the haploid number occurs during the first division in the oogone and in the antherid. Since the eggs of these plants induced to develop without fertilization contain the haploid number of chromosomes, one can assume, unless a regenerative doubling in their chromosome number occurs, that the nuclei of the sporelings contain the haploid number. It would be of interest to grow these parthenogenetic sporelings to sexual maturity and to investigate the chromosome behavior especially during oogenesis and spermatogenesis. Hoyt has carried sporelings of *Dictyota* to maturity by sowing the spores on oyster shells, and transferring these to the open water after the sporelings had become firmly attached. Lewis had used similar methods successfully with the sporelings of certain Floridæ. Fertilized eggs of *Fucus* when allowed to settle down on oyster shells in the bottom of dishes become firmly attached and produce the sporelings. *Fucus* eggs induced to develop by artificial stimuli also produce sporelings on oyster shells. For lack of time I was unable to transfer them to the open water, but the method is suggestive.

UNIVERSITY OF WISCONSIN

ON THE COLLOID-CHEMICAL ACTION OF THE  
DIURETIC SALTS<sup>1</sup>

THIS paper reports a further series of experiments on rabbits which show that *the colloids of the cells and of the juices which bathe them (blood and lymph), and the state in which these exist determine in the main the amount of water such cells and body fluids hold under both normal and abnormal conditions.*

The maintenance of a urinary secretion depends upon two factors, first, upon a supply to the kidney of "free" water out of which to make urine, and second, upon the ability of the kidney cells to do the work necessary in transferring the water from the blood into the uriniferous tubules. Urinary secretion may fail through interference with either of these factors.

The intravenous injection of any amount of blood, blood serum, or a hydrophilic colloid in which all the water is bound to the colloid, is followed by no increase in urinary secretion. This is because no "free" water is given. The same amount of water when given "free," as in the form of a saline solution, is followed by a prompt increase in urinary flow.

When equal amounts of sodium chloride solution are injected we get increasingly greater amounts of urine with progressive increase in concentration of the salt. This is because the salt dehydrates the body tissues, and the "free" water thus obtained is added to that which is being injected. The salt owes its action as a diuretic primarily not to any effect upon the kidney, but to its action in dehydrating the colloids of the whole body.

When equal amounts of equimolecular solutions of different salts are injected it is found that the order in which these produce diuresis is the same as the order in which they dehydrate (protein) colloids. Thus in a series of chlorides the metals arrange themselves in the following order, in which that most powerful in producing a diuresis is named last: sodium, magnesium, strontium, calcium. In a series of sodium salts the acid radicals arrange

themselves as follows: chloride, nitrate (?), bromide, iodide, acetate, phosphate, sulphate. The greatest diuresis of all is produced by a salt which is made up of a powerfully dehydrating base with a powerfully dehydrating acid, for example, magnesium sulphate.

*The diuretic action of these different salts parallels completely their dehydrating effect upon (protein) colloids, a fact which again indicates that they owe their action primarily to their effect upon the body as a whole, acting as diuretics only as they furnish a working kidney "free" water.*

The experiments also betray no evidence of an antagonism between monovalent salts such as those of sodium, and bivalent salts such as those of calcium, strontium, etc. Such salts act *synergetically*, not antagonistically, in physiological reactions, just as they do in test-tube experiments on simple protein colloids.

It is impossible to explain these salt effects upon any osmotic basis, for there exists not even the grossest parallelism between the physiological effect and the osmotic pressure of the solutions employed. Our critics have maintained that osmotic phenomena dominate the picture of absorption and secretion in "living" tissues. They have grown willing to grant that the colloidal theory is operative in "dead" tissues. In the described experiments the osmotic element can hardly be found; the colloidal element appears plainly in every one of them. It is needless to add that our rabbits were alive.

The detailed laboratory findings upon which this article is based have been submitted for publication in the *Kolloid Zeitschrift*.

## SOCIETIES AND ACADEMIES

THE AMERICAN MATHEMATICAL SOCIETY

THE one hundred and sixty-third regular meeting of the American Mathematical Society was held at Columbia University on Saturday, April 26, extending through the usual morning and

<sup>1</sup> A preliminary communication.

afternoon sessions. The attendance included fifty-seven members. President E. B. Van Vleck occupied the chair, being relieved by Ex-Presidents H. S. White and T. S. Fiske. The following new members were elected: Professor E. H. Jones, Daniel Baker College; Mr. L. B. Robinson, Johns Hopkins University; Dr. H. M. Sheffer, Cornell University; Dr. W. B. Stone, University of Michigan; Professor F. B. Wiley, Denison University. Six applications for membership were received. Professors D. R. Curtiss and P. F. Smith were elected members of the editorial board of the *Transactions* to succeed Professors Böcher and White, who retire in the fall.

The following papers were read at this meeting: E. L. Dodd: "The error risk of the median compared with that of the arithmetic mean."

B. M. Batchelder: "The divergent series satisfying linear difference equations of the second order."

P. M. Batchelder: "The hypergeometric difference equation."

H. J. Ettlinger: "On a generalization of a Sturmian boundary problem."

R. L. Moore: "Concerning pseudo-Archimedean and Vollständigkeit axioms."

J. E. Rowe: "The relation between the pencil of tangents from a point to a rational plane curve and their parameters."

E. G. Bill: "Analytic curves in non-euclidean space (third paper)."

Joseph Slepian: "On the functions of a complex variable defined by a differential equation of the first order and the first degree."

Nathan Altshiller: "On the cubic with a double point."

C. F. Craig: "Ruled surfaces associated with certain rational space curves."

H. M. Sheffer: "The generalized principle of duality in Boolean algebras."

T. H. Gronwall: "On the maximum modulus of an analytic function."

L. L. Small: "Note on the summability of properly divergent series."

Maurice Fréchet: "Sur les classes V normales."

Maxime Böcher: "An application of the conception of adjoint systems."

G. D. Birkhoff: "Note on the gamma function."

G. D. Birkhoff: "Solution of the generalized Riemann problem for linear differential equations, and of the analogous problem for linear difference and  $q$ -difference equations."

L. P. Eisenhart: "Transformations of Guichard."

E. V. Huntington: "Sets of independent postulates for betweenness (second paper)."

A. D. Pitcher: "On the connection of an abstract set, with applications to the theory of functions of a general variable."

A. D. Pitcher: "Concerning the property  $\Delta$  of a class of functions."

R. G. D. Richardson: "Oscillation theorems for a system of  $n$  linear self-adjoint partial differential equations of the second order with  $n$  parameters."

H. H. Mitchell: "On some systems of collineation groups."

H. S. Vandiver: "Symmetric functions formed by certain systems of elements of a finite algebra, and their connection with Fermat's quotient and Bernoulli's numbers."

C. A. Fischer: "The derivative of a function of a surface."

C. T. Sullivan: "Properties of surfaces whose asymptotic curves belong to linear complexes."

S. D. Killam: "A note on graphical integration of a function of a complex variable."

K. P. Williams: "On the asymptotic form of the function  $\Psi(x)$ ."

M. G. Gabba: "A set of postulates for general projective geometry in terms of point and transformation."

W. A. Hurwitz: "Postulates sets for abelian groups and fields."

Edward Käsner: "The interpretation of the Appell transformation."

G. M. Green: "Systems of  $k$ -spreads in an  $n$ -space."

J. W. Young: "A new formulation for general algebra."

J. W. Young and F. M. Morgan: "The geometry associated with a certain group of cubic transformations in space."

The summer meeting of the society will be held at the University of Wisconsin, Madison, Wis., during the week September 8-13. The last four days of the week will be devoted to a colloquium, at which courses of lectures will be given by Professor L. E. Dickson, of the University of Chicago, on "Certain aspects of a general theory of invariants, with special consideration of modular invariants and modular geometry"; and by Professor W. F. Osgood, of Harvard University, on "Topics in the theory of analytic functions of several variables."

By William Rickatson Dykes

With 48 colored plates and 30 line drawings in the text.

The volume brings together the available information on all known species of Iris. The most striking feature of the book is the life-size colored plates, reproduced from original drawn from living plants—making it a volume of great beauty as well as of scientific importance.

254 pages, demi folio, half morocco; \$37.50,  
postpaid, \$38.36.

The University of Chicago Press

5753 Ellis Avenue

Chicago, Illinois

## GOODE'S BASE MAPS

For classes in geography, geology, economics, history, etc. 18 subjects. Two sizes: 8x10½ in., 1c; 15x10½ in., 3c; postage extra. Perforated for notebook; suitable for ink or pencil. Samples on request.

The University of Chicago Press  
Chicago, Illinois

### OUR 1913 CATALOG

Contains many new instruments, all new illustrations, lowest prices and valuable information of interest to every science instructor. Send us your name and address and we will send you a free copy.

CHICAGO APPARATUS CO.

Sales Dep't

CHICAGO APPARATUS CO., CHICAGO, ILL.

## JULIEN'S POWER AND FOOT LATHES

Use of Geologists, Mineralogists, Petrographers, Metallurgists, Mining Engineers, in SLICING and POLISHING all hard substances, rocks, etc., and in preparation of MICROSCOPIC THIN SECTIONS.

GUSTAVUS D. JULIEN

3 Webster Terrace NEW ROCHELLE, N. Y.

## ROMEIKE'S PRESS CLIPPINGS

are now an absolute necessity for every scientific man. By methodical searching through the most important papers and periodicals published in this country and abroad we are able to supply you at short notice with information on any subject which perhaps you would be unable to find yourself in libraries or reference books after spending days or even weeks at such a task. Write for further information.

MS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

THE education of medical students has been a subject of perennial interest to both teachers and practitioners for a long time, and although great advances have been made, there is still general dissatisfaction with the results as shown by examination tests and the ability of recent graduates to meet the emergencies or even ordinary duties of professional work.

At the meetings of the council on medical education of the American Medical Association, the confederation of examining boards of the United States and our own association, the faults in preliminary education, in professional training, and the needs of still greater clinical opportunities, have been pointed out and are familiar to you all. Out of all these discussions, two general educational remedies have been advocated.

1. That one or two years of college work, which shall include one year of chemistry, physics and biology, be added to the preliminary training.

2. That a hospital or clinical year be added, making the medical course, as measured by the standards of England and Germany, six years.

In these two propositions certain questions arise which concern this association especially. For us the questions are not merely academic, but questions of administration, standards and pedagogies.

The house of delegates of the American Medical Association at its recent meeting

<sup>1</sup> Presidential address, delivered before the Association of American Medical Colleges at Chicago, February 26, 1913.

decreed that for a medical college to be put in the highest rank, the requirement of one year of college work, including instruction in chemistry, physics and biology, is necessary. This has focused attention on this proposition and many colleges will feel compelled to require it.

In discussing this proposition, the first question that arises is: How is the student to obtain this year's work in the designated sciences?

In states with state colleges or universities, the question has been answered. The high school and university courses are so correlated that with a minimum amount of disturbance the student passes from one to the other. The financial aspect is not a burdensome one, as the fees in the state-supported institutions are relatively small. But in the greater part of the country no such coordination exists, the colleges and universities are disassociated from the high schools, so that there is a greater or less impediment to students passing from the high school to the colleges, as they are not accepted on their high-school credentials. In some, the students are admitted only on examination in addition to their credentials, and others demand special preparation in subjects not included in the high-school course. Universities and colleges should feel it their duty to correlate their entrance requirements with the high-school courses of their locality.

In this connection another obstacle is met with in localities where the universities and colleges are not part of the general educational system, *i. e.*, the attitude of these institutions toward one- or two-year students who are taking the course to meet the medical school requirements. It does not, however, apply to universities with medical schools. The universities frankly admit that they do not want these students, and when we discuss the requirements as re-

lated to sciences and languages with them, they say: "Why should we modify our curriculum to meet the needs of these one- or two-year students? We are not conducting this college as a preparatory school for technical or professional education." And the head of one of the largest universities in the east with no professional school attached, said: "If I find men coming here to meet this requirement, I will change the course so that they can not get the science branches demanded in less than three years."

To meet this requirement, must the course be taken only in an institution having the right to grant the B.A. or B.S. degree? Should the requirement read: "One year's work of college standard, which year must include instruction in chemistry, physics and biology. This year must be in addition to the high-school course"?

This raises at once the most important question of equivalents and all the dangers of evasion. It has been suggested that these courses might be given in technical high schools which only admit students after the completion of a high-school course, and in support of the suggestion, it has been claimed that such a course would be much more definite than that given in many literary colleges, and it would be under the supervision of the educational department of the state. Many deny the right of high schools to do the work of the colleges, and, in addition, urge that it is not meeting the spirit of the requirement.

This raises the next question. What is the object of this added year of preparation?

In general terms, the answer is: "Power to grasp professional subjects."

Is this power gained best by increase in general education in the so-called "humanistic" or "culture" courses, or by tech-

nical training in the sciences? The view point of the institution in which the instruction is taken will determine the character of the course. In institutions with medical schools, the course will be correlated to the future needs of the student. In colleges without such affiliation, these courses will be part of the general college régime which deals with education so as to insure a wide and general character to the subjects it embraces, whereas it is imperative for the future use of such studies, whether in engineering or medicine, under the pressure of modern life, that the student should be equipped with the necessary knowledge in the shortest possible time that is compatible with thoroughness. From a practical point of view, generalities must be abandoned and definite limits set. Are the undergraduate college teachers willing to do this, or will they insist on generalities?

This raises the question of the cultural value of the liberal courses as opposed to the so-called science or technical subjects. All agree that "the preparatory training for life should be liberal and humanizing; that the course of study in the college, in addition to having a broadening influence, should also inculcate in the student some specific kind of mental training which will fit him better to take a high rank in whatever career he may happen to select." As students enter the college to later select medicine, the studies should by scope, content and method give him the specific kind of mental training that will better fit him for his life work.

While valid objection might be raised against introducing into the college course professional instruction, as defined by Karl Pearson, *i. e.*, "training in the art of a specific profession," this does not hold against technical education in the underlying subjects of a profession, and for the

medical profession these subjects are the natural sciences, chemistry, physics and biology being specified as those most helpful.

It has been said that these subjects are lacking in educational value from the standpoint of "general training"; that they do not provide mental training for the man who has no intention of entering a profession. The answer to this objection is that the fault is not in the subjects, but in the manner in which they are taught, and also in the content of the course. President Hill, of the University of Missouri, has emphasized the value of motive in acquiring knowledge and gaining insight into a subject. "Insight normally brings culture, especially in human life, and vocational motive not only does not interfere with, but tends to foster, the development of a deeper and truer insight into the significance of scientific knowledge."

Can a knowledge of chemistry, physics and biology be acquired in one year of college work with sufficient fulness to be of value to the student in his medical course? There are two opinions on this question: one, that a single year is inadequate; that these subjects should be taught as pure sciences and on general lines with no regard to future use; that in one year the student will have only a verbal acquaintance with things that he does not understand. Those who hold this opinion are urging the two-year course, not so much as a preparation for medicine as for the general cultural value. They would have not more than a single year's work in each of the science branches and more of the general college subjects added.

The other opinion is that one year is a sufficient time in which to gain a familiarity with the *principles* of those subjects which have a bearing on medical sciences.

This is a very different thing from teaching them as medical subjects. It would set definite limits on the course and not try to cover the entire science in a single year. In chemistry the general basic principles underlying the science rather than isolated facts should be taught, and these principles can be learned just as well by studying substances and processes in the laboratory which have a distinct bearing on medicine, rather than on metallurgy or mineralogy. Probably the college course in chemistry is the best standardized of all.

In physics, the student needs a fairly wide knowledge so far as it can be gained without higher mathematical processes. Laboratory instruction should form a large part of it. The important topics are specific gravity or relative density (there should be real understanding of what these terms mean), osmotic pressure and diffusion, hydrostatics, acoustics and its common application to sound, pitch, resonance, optics, laws of refraction and reflection, as applied to mirrors and lenses. Heat; the thermometer, laws of specific heat, cryoscopy, calorimetry and the relation of heat to work. Electricity; the elements of static electricity and of galvanic and foradic currents. In mechanics, the statical aspects only. Much of the dynamics usually taught should be omitted, also the study of absolute temperatures, absolute units. The object of the course in physics is that

the student may gain a comprehensive and connected view of the most important facts and laws of elementary physics. There is need of limiting the course in physics, because the courses in universities and colleges are more adapted to train professional physicists than future practitioners of medicine. The two need a different training. A study of the curricula at many colleges shows that in one single year an elementary course requiring very little mathematics is followed by a highly specialized mathematical course, having practically no reference to the experiences of life.

In the biological course, it is important that the student should become conscious of the characteristics of living things. Without some general biological training, it would be impossible for him to give to his medical physics and chemistry a biological application. By dissection of a few of the lower types, by witnessing a few simple physiological experiments on plants or animals, by examination of simple tissues under the microscope, he should obtain an idea of the correlation between structure and function, the general build of the elementary tissues; and the process of digestion, respiration, assimilation and reproduction, which together make up our conception of a living organism. A comprehensive view of the subject, but well within the power of the student to understand, is rarely given. On the other hand, a great deal of useless information is given and much precious time and energy is wasted on botany, zoology and highly specialized courses.

By such courses, beyond the accumulation of facts in the different sciences which the student may obtain, he should have become an accurate observer, been interested in the art of inquiry, have acquired a fair degree of manual dexterity and use of laboratory instruments, have cultivated proper habits of study and work—in fact, trained for efficient professional study. His mental horizon should be extended, a new attitude of mind toward his work fostered; his reasoning faculties should be developed so that the insistent “*why?*” compels him to seek the answer. To give this training demands that the subjects are taught in an intensive manner, that interest is aroused, that the student feels that the subjects are important, not only as sciences, but for their future professional application. Unfortunately, the generalities

of the college courses do not often give this direction.

It must be borne in mind that it is possible to educate a student away from scientific thought, as well as toward it. It has been disappointing to note the effect of a general college education on medical students. They come to the medical school often unwilling to adjust themselves to the régime. They have lost much of their receptiveness, they are to a degree mentally arrogant, they have a pseudo-philosophical and not a scientific frame of mind. It is for this reason that often the high-school graduate gets more out of the course than the man with a B.A. degree.

In demanding one year of college work as an entrance requirement, the medical schools have not only a right, but a duty, to demand of the colleges that the course be standardized; that it be made worth the students' time, both in content and methods. Otherwise it is useless, both from the cultural and technical standpoint. It will be not a specific, but a quack remedy, prescribed for the cure of our educational illness. I firmly believe in better preliminary education of the medical student, and am only raising these questions that they may be discussed.

What influence will the added year of preliminary training have on the medical course? Will it allow of changes in our present curriculum? For it is conceded that at present it is overcrowded; that the difficulties of medical education are increasing; that the burden is heavy on both teachers and student; that there is a waste of effort that is almost tragic.

The problems of medical education are bound up with the progress in medicine and therefore can not be solved once and for all, but must be constantly under consideration and adjustment. In all consideration of them, certain facts must be kept

constantly in mind. The period of study can not be indefinitely extended. There must be a proper proportion between the period of preparation for and practising of a profession. As Professor Starling has so well put it, "The brain of man does not increase in capacity or in power of assimilation with the growth of science." "How is the necessary limited time of medical education to be most profitably employed in imparting to the student such knowledge as is most useful to him in his future career?" The effect of the overloaded curriculum on the student is most harmful. He gets a smattering of many things, instead of a thorough grounding in principles. He forms faulty mental habits, early becomes surfeited and loses interest in the work; everything is gauged by examination value; he has no sense of proportion, small details and facts loom large, basic principles are unimportant. At what point should the unloading begin? What ballast should be thrown overboard?

Notwithstanding the work of the committee on curriculum of this association and that of the council on medical education of the American Medical Association, the usual medical course still contains much useless ballast, some of it traditional, some of it due to demands of state board examinations and some gradual "accretion" due to a desire to meet the advances in medical sciences.

Professor Welch, in opening the discussion on "The Medical Curriculum" at the meeting of this association at Baltimore, said:

One of the fundamental things is to inquire, What is the object of medical education? To make good doctors; there is no question that that should be the underlying conception in our schemes for medical education, and unless you can define a given course as bearing on that training, it has no place in the medical curriculum. If the training in physiology can not be shown to be to make good doctors, it is

not defensible. The same can be said of pathology, or any other subject in the curriculum. The ultimate aim of medical education is to make good practitioners of medicine. Another thing that confronts us at the start of any consideration of the medical curriculum is: What kind and what amount of knowledge can the student acquire during the four years of his medical education? The most you expect is to give to the student a fair knowledge of the principles of the fundamental subjects in medicine, and the power to use the instruments and methods of his profession; the right attitude toward his patients and toward his fellow members in the profession; above all, to put him in the position to carry on his education, because his education is only begun in the medical school. The student does not go out a trained practitioner, a trained pathologist, or a trained anatomist or a surgeon.

President Pritchett in the introduction to the "Bulletin on Medical Education in Europe" says:

Even if one may assume that students enter the study of medicine properly trained in the fundamental sciences, the problem of the curriculum is a serious one. The report shows a general tendency toward overburdening. The question naturally arises, What ought the course of study of a technical or professional school to accomplish? The medical school can not turn out finished doctors. It can not teach all that it is important for the practitioner to know. Under these circumstances it does best to accept frankly certain limitations, and so to train its students that they will be disposed subsequently to remedy their own deficiencies. Inclination of this kind appears most likely to result from a training that prescribes only the indispensable minimum, requiring in addition more thorough performance in a few directions and leaving opportunity for still further effort to those of greater energy, interest or ability.

Is not some of the overload due to our having ignored the above facts, because we have tried to teach all the sciences and all the art and science of medicine, to turn out specialists in medical sciences, in research work, and in medicine and surgery.

The past decade has seen a most marvelous improvement in the teaching of medical sciences and opportunities for laboratory

work. Gone, never to return, are the purely professional courses in anatomy, chemistry and physiology, given by busy practitioners or recent graduates, whose knowledge of the subject was but little in advance of the students, and who were able to repeat a few simple experiments. To-day the laboratory courses in the medical sciences are far more extensive than even the German schools. In this country the laboratory courses are paramount and the lecture courses subordinate; in Germany it is the reverse. The development of these courses has been so rapid that the necessity for setting limitation on them has not been observed. President Pritchett says:

The medical curriculum, extended as it is in Europe, over five years, has reached the limits of its capacity; it can contain no more. Exactly the same process has occurred in medicine as has taken place in the training of engineers. In fact, experience in these two kinds of technical education during the last fifty years has been strikingly similar. Most naturally the medical school and the engineering school have endeavored to include in their teaching some knowledge of the new sciences developed in the last half century and of their application. As a result, the burden devolved upon students of medicine and of engineering has grown enormously. The respective curricula have been formed almost altogether by accretion, something being put in, little or nothing taken out. As a result, both the medical student and the engineering student are called upon to carry, not only a heavier load, but a load made up of more parts.

As students come to the medical schools with better preparation in the sciences, there is a tendency to add more and more detail; to extend the laboratory courses and insist on all the precision, the rigor and the abstraction of the research laboratory; to teach the subjects as pure science and not as applied; to lose sight of the ability of the student; to go beyond the need of the future practitioners of medicine, and plan the course as if all were to be

chemists, physiologists, pathologists or research workers. The whole body of students should not be compelled to spend a disproportionate amount of time and energy upon topics which will be of use to a few only. Opportunity should be given to those who wish to pursue any subject beyond that given as part of the general instruction, but unfortunately our rigid curriculum prevents it. The student's time is too fully occupied to allow of electives or to take extra work in subjects in which he is interested, without neglecting obligatory courses. It has been well said that our system is a "lock-step" one.

The student should be so instructed in the fundamental principles of the science subjects that after graduation he may keep pace intelligently and be able to utilize further discoveries of these sciences as applied to scientific medicine. Beyond this we can not go.

In our attempt to make our student scientific we are defeating our object by insisting on too great detail, before he can understand the principles. The teaching of a subject as a pure science, without application to clinical subjects, causes him to have no motive or interest in it and to throw it overboard as soon as examinations are past.

While all agree that the inductive method is the proper one, when pushed to the extreme the method breaks down. This is a woeful waste of the students' time in the "work it out for themselves" method of some teachers.

The statement is frequently made that students do not carry with them beyond the examination period that general knowledge of anatomy, chemistry, physiology and pathology which should be a lifelong possession.

The reason that the students do not have

a better grasp on the science subjects is because medical education has become less homogeneous. Under the old system, the primary or science subjects were taken at the same time that the clinical ones were. The student thus gained an inkling of the relation of his science subjects to his clinical work. At the present time, this relation is not apparent to the student unless it is pointed out to him. The science years are becoming more and more divorced from the clinical, and the fact should be recognized and the tendency corrected.

From my study of the methods of instruction given in many of the medical schools, I believe that teachers of the science branches are largely to blame for this. That the science subjects should be taught by specialists is conceded by all, and they are rightly in charge of the years devoted to their subjects. They have had a hard fight to gain recognition and are hostile toward any movement to introduce into these years any clinical work, and many have gone so far as to insist that it is not their function to give any definite application to the subject. This has made necessary the introduction of applied courses in the different subjects to bridge the gap between the science and clinical years. Too often these courses when given have to be taught by teachers not connected with the science subjects. The science teachers, especially if engrossed in research work, are too apt to teach only the more scientifically interesting features and consider that they have done their duty when they have given the lecture courses of their subject, and leave to their assistants the more important laboratory instruction. The majority of these giving the laboratory courses are young and inexperienced teachers who have not had the advantage of a medical training, and their

only knowledge of the subject is that obtained in the pure science courses. If any question of application arises, they are unable to answer it and therefore discourage all such inquiries or resent them as "catch questions."

Teachers in the science branches should be in thorough sympathy with the future professional work of the students, and I am of the opinion that teachers in medical schools should have taken a complete medical course as part of their training. There are many eminent teachers in medical schools who have not had this training, but they have been long in contact with medical institutions and have a saving sympathy with the clinical side. In the large university schools and where the school is divided, there is danger in this lack of sympathy with clinical work, which attitude the science teachers are only too ready to criticize harshly in the clinical man if he does not show sufficient interest in their particular science.

Medical progress is being retarded by lack of coordination of science and clinical departments. The lack of training in clinical medicine too often prevents the science teacher from being of assistance to the clinician. Medical and surgical methods do not always fit in with laboratory technique. The complexity of the problem causes him to give little scientific value to the investigations not made in a laboratory. It is this attitude of the science teacher toward the introduction of clinical work or clinical methods in the first two years of the course, that is causing not only the student to fail to appreciate the value of and becoming interested in the subjects, but also to make him less able to apply the knowledge that he has gained of laboratory technique to his work in the clinic and wards. His *work* in the laboratory has been on frogs and the lower ani-

mals only. When he comes to his clinical years he finds that he can not use the apparatus with which he has become familiar to human beings. He finds new factors enter into the experiment which confuse his previously formed conceptions; he can not interpret his findings. The science teacher claims that this applied instruction should be given by the clinical teachers and also says that they should be competent to do it, which latter contention we grant, but what are the two years of instruction in the laboratories for but to prepare the student for his clinical work? Wherever possible methods and apparatus should be employed that can be used in clinical investigations. The burden of this instruction should not be thrown on the clinical years, already so overcrowded as to make a hospital year a necessity.

To insure a better correlation between science branches and clinical years and allow of unloading, the hard and fast lines that are tending to separate the second and third year of the course should be obliterated. As students come better prepared in the underlying sciences and are able to accomplish more in the same time, instead of extending the courses in pure science, correlated clinical laboratory courses should be introduced in the second year.

If the teaching staff of the science branches can not give these courses, then clinical teachers, most likely young men who have been trained in laboratory method, should give them. This would be the best introduction possible for the clinical subjects, and students so prepared could more rapidly advance in the third year. It would permit of omitting much of the lecture course in this year and allow an early contact with clinical material. To obtain such readjustment hearty coopera-

tion is needed from science and clinical teachers.

The establishment of state board examinations has been of great aid to medical education. It has raised the general standards of the profession, and secured a more uniform curriculum over the entire country. It has, however, had a decided influence on the overloading of the curriculum, as they have yoked the old methods with the new. The necessity for arranging the examinations to meet the training of graduates of years ago, as well as the recent, has been detrimental to progress and has encouraged cram-quiz book methods and put a premium on ability to answer questions, calling for mere detail information of the subjects. The time has come when state boards of examiners should recognize the changes that have occurred in methods of medical education; that the student who is best educated has not the best knowledge of small and unessential details; that to meet the requirements of the state boards he has to have recourse to quiz compends for much that is of no practical use to him. The new methods have been in force long enough to establish a class by itself and for licensing there should be one type for the graduate of former days and one for the more recent. As at present conducted, both in content and method, it is satisfactory to neither class. This association, by the cooperation of the Federation of State Medical Boards, could be of great value in correcting this defect. The state boards are appreciating this defect as well as medical educators, and would welcome any plan which would allow of a practical examination, both laboratory and clinical.

The difficulty in arranging such an examination is the lack of money and laboratory and clinical facilities. States with centers of medical education could easily get the fa-

cilities by holding the examinations in those places and using the college laboratories and clinics and hospitals. Different dates could be arranged for various sections. The states should consider that it is their duty to provide the necessary funds. That such a plan is feasible is shown by the ease with which large numbers of candidates for the positions of hospital interne are examined, both by written and practical examination.

Examinations have, and probably will be, the means of testing the character of instruction given by the medical schools and the knowledge of the students, but they should be adapted to give a true index. They must coordinate with the methods of instruction. At the present time they do not. Rating colleges according to the ability of students to pass these examinations is putting a premium on only such instruction as will enable the student to successfully meet the test. It is exalting narrow training over broad education. Evaluating bodies should not place too much value on the percentage of failures and passing as an index of instruction in the colleges.

From members of the general profession one constantly hears the harsh criticism that recent graduates are deficient in detailed knowledge of this or that specialty. That while skilled in laboratory methods of diagnosis, they have acquired little of the art of medicine. They insist that many new topics ought to be added to the course of study.

Much of the overburdening of the clinical years has been due to adding topics or extending courses in the special branches to meet these criticisms. The profession as a whole should appreciate that the student must, in his college course, gain his training in scientific methods if he is ever to have it. That only the essentials can be

taught thoroughly. Faulty training in the essentials is caused by trying to do too much. That only so much of the special branches can be given as to make them safe practitioners, not immature specialists.

It is desirable that every practitioner should know many things about his relation to society at large, to allied professions and their problems, to organize charities and their activities, and the business methods of his own profession. However, these topics should not be introduced into the medical curriculum, they are part of the postgraduate education, which every physician should feel it his duty to acquire.

The need of unloading and correlation is a most pressing one, and it is our duty as an association of medical colleges to point that way.

The complex question of a hospital or clinical year has been under discussion for some time by this and other associations. That the student needs more extended clinical experience before beginning the practise of his profession is conceded by all. There is not the same unanimity of opinion as to the advisability of making a clinical year obligatory or whether it should be demanded by the colleges for the degree of M.D. or by the states as a requirement for the right to practise.

Before a decision can be reached many administrative and pedagogic questions must be answered. As the necessary data have not been gathered, this association should cooperate with other bodies in making a collective investigation of the subject. As a large percentage of medical graduates now voluntarily take one or more years of hospital internship I believe the first step should be to give both academic and legal recognition to this postgraduate training.

EGBERT LEFEVRE

UNIVERSITY AND BELLEVUE  
HOSPITAL MEDICAL COLLEGE

#### THE PSYCHIATRIC CLINIC AND THE COMMUNITY<sup>1</sup>

THE increasing interest shown in the study of human activities is one of the most significant and hopeful signs of our times. Momentous as was the impulse given to science by Copernicus, Galileo and Newton one result of their investigations was to direct attention to a universe in which human beings were considered to be merely passive observers of natural phenomena. So absorbed did man become in formulating hypotheses to explain a theoretical universe of which he did not form a part, and in delving into the records of his own past history, he neglected the study of present activities. At last the course of events warned him that the lessons of remembrance or the hypertrophied historical sense had become "a malady from which men suffer."

The dedication of a psychiatric clinic is an event of more than ordinary importance to a community, as it marks the awakening of intelligent interest in man, as an active thinking being. Having striven for centuries to improve the methods for recording his fanaticisms, superstitions, sins of omission and of commission, and failures to adjust life to meet new conditions, he has begun at last to take rational measures to improve his lot, and to acquaint himself with the laws on which the social organism rests. As the value of this benefaction to the community will depend directly upon the intelligent use of resources and energy made available for rendering more effective service to humanity, may we not profitably devote a few moments in attempting to formulate some of the problems to the solution of which this clinic is dedicated. Errors in judgment committed now, in

<sup>1</sup> Address delivered at the opening exercises of the Henry Phipps Psychiatric Clinic, The Johns Hopkins Hospital, Baltimore, Md., April 16, 1913.

estimating the scope and the character of the investigations to be carried on in this building, might defeat the efforts of those upon whom the responsibility of equalizing opportunity and achievement must fall.

This clinic, in a peculiarly distinctive manner, typifies the human as well as the humane spirit of the twentieth century. During the seventeenth and eighteenth centuries the physical sciences had succeeded in breaking away from the traditions and superstitions which had hampered their development. Astronomy had been divorced from astrology, chemistry from alchemy, and the foundations of geology had actually been laid. In the nineteenth century the renaissance of the biological sciences was accompanied by the formulation and expression of a rational idea of man's position in cosmos. Towards the close of the eighteenth and the beginning of the nineteenth century a few investigators had already called attention to the importance of studying the activities of human beings; but not until the second half of the last century was there any realization of the fact that the most interesting phenomena of the universe for human beings to study were their own activities. How do we live, move and have our being?

To the lay mind the term psychiatry often suggests a very limited field in medical science, but those who take an active part in the work of this clinic will easily appreciate that they are engaged in attempting to find the solution of problems of far greater importance than any relating merely to the care of patients suffering from mental or nervous disorder. Anomalies of thought and conduct are studied in order that the knowledge acquired may be applied directly to making life for the majority of persons pleasanter and more effective. Institutions of this character are intended primarily for the study of

human nature along broad biological lines.

We are justified in considering disease as an analytical process which reduces to a comprehensive form the complex activities we designate collectively as health. An intimate knowledge of abnormal states of mind and body is, as Pinel affirmed, a key that unlocks the secrets of human history. By making use of nature's contrast of functions we may also gain an insight into that continuous process of adjustment we call life. From the study of disease the facts have been gathered for the foundations upon which modern preventive medicine has been established, and through it a new meaning has been given to life and greater efficiency in thought and action to those who profit by the lessons of science. For centuries the different parts of the body have been studied by physicians, and a knowledge of the structure and function of the separate parts has been attained. It is essential, if we are to comprehend the fundamental mechanisms of response of the organism, that we familiarize ourselves with the laws which govern the relationship of all these organs as they are expressed in each individual, and we must accustom ourselves to study man as a living organism.

Living beings have the capacity of expressing their integral unity as individuals, and in the case of man there are special mechanisms of adjustment, collectively designated as the personality. The complex adjustments synthesized in the personality may easily be deranged by interference with the activities of organs or by disturbing the capacity for adaptation; the chief function of sense organs, brain and nervous system. We all know how intimately dependent human beings are upon their environment. Changes in the latter call for delicate and immediate adaptation, and it may be said the problems of psy-

chiatry relate to the determination of the causes which give rise to imperfect adjustments.

A great blessing was conferred by science upon humanity when the problems of psychiatry were restated in biological terms. Life was recognized as a process of adjustment, relatively perfect in health and imperfect in disease; while that metaphysical term insanity arbitrarily reserved to designate certain forms of unsuccessful adjustment was cast into the rubbish-heap together with the chains, straight-jackets and hand-cuffs which had long tortured the lives of patients. Out of hazy mystical conceptions entertained in regard to the nature and genesis of activities described as thought and conduct sprang new ideas potent to inspire the minds of investigators, capable not only of bringing about great practical reforms in the care of the insane, but also in improving the methods for attacking the problems relating to human thought and conduct.

As the ultimate success of the work to be carried on in this clinic, more than in any other department of the hospital, will depend upon cooperative endeavor, I may be permitted to emphasize what seems to me to be an important factor in organization and administration. The patients presenting themselves for treatment are subjects of imperfect adjustments in the life process. The time during which they remain under observation in these wards will represent relatively brief epochs of life, and the records of cases will often give but cursory glimpses into the genesis, duration and progress of imperfect life adaptations. In order to serve the high purpose for which it is planned and dedicated this clinic should be regarded as an important link in a chain of agencies, home, school, college, other hospitals and institutions; in fact the entire social organization with

which it is essential constant sympathetic contact should be maintained. Only by the establishment of these relationships can progress in the study of life processes be made.

May we express the hope that in attempting to estimate the value of the work accomplished in this clinic the public expression of opinion should be tempered by charity and patience. Although the field of investigation, which includes the consideration of the factors determining human thought and conduct is the most interesting one in modern medicine, let us not forget that it is the last one to be thrown open to investigators.

The methods of investigation necessarily employed will not appeal to the imagination of the public. The inspiration essential to solve the problems of modern psychiatry will probably not flash into consciousness as did the visions that guided the observer watching the lamps swing in the cathedral or the apple fall from the tree, but it will come gradually only after patient quiet effort, similar to that which finally rewarded the author of "The Origin of Species," and gave a new meaning to life. The realization of the ideals to which we do homage to-day will mark the time when, in Goethe's words,

Vernunft fängt wieder an zu sprechen,  
Und Hoffnung wieder an zu blühen.

STEWART PATON

---

#### TENTH INTERNATIONAL VETERINARY CONGRESS

THE organizing committee of the Tenth International Veterinary Congress to be held in London, August 3 to 8, 1914, made a strong appeal to the veterinary profession of the different countries to organize national committees as early as possible in order that an appropriate propaganda may be carried on for the congress, and thereby a large attendance assured.

In view of this and the consideration that the annual meeting of the American Veterinary Medical Association will not take place until September, 1914, it was deemed advisable to organize without delay a national committee for the United States. At the advice of Dr. John R. Mohler, president of the American Veterinary Medical Association, Dr. L. Van Es, who was the official representative of the Ninth International Veterinary Congress at The Hague, was asked to accept the chairmanship, to which he willingly consented, at the same time requesting me to act as the secretary of the national committee.

Dr. Van Es named the following vice-presidents for that committee: Dr. A. D. Melvin, Washington, D. C.; Dr. K. F. Meyer, Philadelphia, Pa.; Dr. C. J. Marshall, Philadelphia, Pa.; Dr. J. R. Mohler, Washington, D. C.; Dr. J. Hughes, Chicago, Ill.; Dr. W. H. Dalrymple, Baton Rouge, La.; Dr. E. C. Schroeder, Washington, D. C.; Dr. V. A. Moore, Ithaca, N. Y.; Dr. E. C. Cotton, Minneapolis, Minn.; Dr. J. S. Anderson, Seward, Nebr.; Dr. S. Brenton, Detroit, Mich.; Dr. O. A. Cary, Auburn, Ala.; Dr. D. S. White, Columbus, Ohio; Dr. S. B. Nelson, Pullman, Wash.; Dr. M. Francis, College Station, Texas; Dr. W. F. Crewe, Devils Lake, N. Dak.

With the organization completed, the committee now desires to commence their work and to create a wide interest among the veterinarians of the United States, thereby securing a creditable delegation from our profession.

Sir Stewart Stockman, honorary secretary of the organizing committee, in a letter addressed to Dr. A. D. Melvin, expressed his desire to obtain at an early date the names of those who desire to act as reporters for the various subjects to be discussed at the congress, also at the same time enclosing a copy of the list of subjects which are to be discussed at the Tenth International Veterinary Congress. The list is prepared as follows:

#### GENERAL MEETINGS

1. Foot and mouth disease.
2. Tuberculosis, including the relationship of the so-called types of tubercle bacilli.

3. Epizootic abortion.

4. Public control of the production, distribution and sale of milk in the interests of public health.

#### Section I.—Veterinary science in relation to public health.

1. Meat poisoning—its pathogenesis and the measures necessary to guard against it.
2. General principles to be observed in the inspection of the carcasses and organs of tuberculous animals with a view to determining their safety as articles of human food.
3. Disinfection of wagons.

#### Section II.—Pathology and bacteriology.

1. John's disease.
2. Bovine piroplasmoses (European), with special reference to their etiology.
3. Ultra-visible viruses.
4. Distemper—etiology and vaccination.

#### Section III.—Epizootiology.

1. Anthrax.
2. Swine fever.
3. Glanders.
4. Sarcoptic mange of the horse.

#### Section IV.—Veterinary medicine and surgery.

1. Anesthesia—local and general.
2. Laminitis.
3. The surgical treatment of roaring.
4. The use of drugs in the treatment of disease caused by nematode worms.

#### Section V.—Tropical diseases.

1. Diseases transmitted by ticks; their classification, treatment and prevention.
2. Diseases transmitted by winged insects; their classification, treatment and prevention.

It is also planned to arrange in connection with the Tenth International Veterinary Congress a study tour for veterinarians, under the auspices of the Bureau of University Travel, the itinerary of which will include a trip through Belgium, France, Switzerland, Italy, Hungary, Austria, Germany, Holland and England, thereby affording the veterinarians desiring to attend the congress a splendid opportunity of studying all phases pertaining to veterinary medicine in the different countries.

Such a tour will be the first undertaken by a body of veterinarians from this country and would afford splendid advantages to members of the profession, affording not only pleasurable but also educational advantages; be-

sides such a body would receive exceptional courtesies from the authorities abroad.

It is only natural that a competent director of the tour will be named who, with extensive experience in travel abroad and a knowledge of languages, will be in position to care for the welfare of the party in the best possible way.

It is hoped that the members of the profession will aid the committee in its work. Those who desire further information will be given full attention.

ADOLPH EICHHORN,  
*Secretary*

#### SCIENTIFIC NOTES AND NEWS

THE Paris Academy of Sciences has elected Professor W. M. Davis, of Harvard University, a correspondent in the Section of Geography and Navigation, in the place of the late Sir George Darwin.

THE University of California has awarded an honorary degree to Mr. John Muir, "born in Scotland, reared in the University of Wisconsin, by final choice a Californian, widely traveled observer of the world we dwell in, man of science and of letters, friend and protector of nature, uniquely gifted to interpret unto other men her mind and ways."

THE Halle Academy of Sciences has awarded its gold Cothenius medal to Dr. Leonhard Schultze, professor of geography at Marburg.

DR. OTTO H. TITTMAN, chief of the Coast and Geodetic Survey, has been made an honorary member of the Berlin Geographical Society.

THE Hanbury medal of the Pharmaceutical Society, London, has been awarded to Dr. Frederick Bilding Power, Ph.D., LL.D. The medal is awarded biennially for original research in the chemistry and natural history of drugs. Dr. Power, who is director of the Wellcome Research Laboratories, London, is an American by birth.

THE council of the Royal Society of Arts has passed the following resolution:

On the occasion of the fiftieth award of the Albert medal of the Royal Society of Arts, the council of the society desire to offer the medal to H.M. King George V., for nine years president, and now patron of the society, in respectful recognition of his Majesty's untiring efforts to make himself personally acquainted with the social and economic condition of the various parts of his dominions, and to promote the progress of arts, manufactures and commerce in the United Kingdom and throughout the British Empire.

THE gold Nachtigall medals of the Berlin Geographical Society have been awarded to Duke Adolf Friedrich, of Mecklenberg, and Professor Hans Meyer, for explorations in Africa.

PROFESSORS J. L. COOLIDGE, E. V. HUNTINGTON and G. D. BIRKHOFF, of the division of mathematics of Harvard University, have been elected to membership in the American Academy of Arts and Sciences.

THE Rumford Committee of the American Academy, at its last meeting, voted the following appropriations: to Frederick G. Keyes, of the Massachusetts Institute of Technology, \$300 to be used for the payment of assistants in the computation of thermodynamic tables for ammonia, and to Professor Theodore W. Richards, of Harvard University, \$100 to be used in aid of the publication of the Annual International Tables of Constants.

SECRETARY LANE has announced a reorganization of the reclamation service. F. H. Newell, director of the Reclamation Service, will be chairman of a new Reclamation Commission. The commission will consist of five members, who, besides Chairman Newell, will be George Barton French, in charge of operation and maintenance; A. P. Davis, chief engineer; Judge Will R. King, of Oregon, chief counsel, and one other, who will have charge of the contracts and finances.

DR. W. D. BIGELOW, for many years a member of the Bureau of Chemistry, U. S. Department of Agriculture, has resigned from the government service to take charge of the laboratory of the National Cannery Association to be established in Washington.

MR. NATHAN C. GROVER, of New Jersey, has been appointed chief hydraulic engineer of the water-resources branch of the U. S. Geological Survey, to succeed Mr. Marshall O. Leighton, who resigned early in May to plan and supervise land drainage in Florida.

MR. C. G. ELLIOTT, chief of drainage investigations in the Department of Agriculture, has left the government service to go into private business.

MR. E. N. WENTWORTH, associate professor of animal husbandry at the Ohio State College, has become associate editor of *The Breeders' Gazette*.

DR. T. N. CARVER, David A. Wells professor of political economy at Harvard University, has been appointed director of the Rural Organization Service, a new branch of work just organized by the federal Department of Agriculture, and has been granted leave of absence from the university so that he may be able to carry on the new work he has undertaken.

MR. L. F. RICHARDSON, assistant lecturer in physics at the Municipal School of Technology, Manchester, has been appointed superintendent of the Geophysical Observatory, Eskdalemuir, in succession to Mr. G. W. Walker, resigned.

MR. T. L. ECKERSLEY, B.A., of Trinity College, Cambridge, has been appointed assistant at the Helwan Observatory, Egypt, to assist in the magnetic work.

PROFESSOR VON DUNGERN, of Heidelberg, has been appointed director of the newly established institute for experimental cancer research at Hamburg-Eppendorf.

DR. W. A. MURRILL, assistant director of the New York Botanical Garden, has sailed for Europe to study especially the conditions of the growth of trees in cities.

THE Academy of Science of Oregon has elected officers as follows:

*President*—N. H. Laurie.

*First Vice-president*—A. R. Sweetzer.

*Second Vice-president*—T. D. Beckwith.

*Third Vice-president*—W. L. Finley.

*Secretary*—Miss Jane Stearns.

*Treasurer*—A. L. Knisley.

*Librarian*—A. W. Miller.

*Trustees*—A. L. Knisley, E. A. Beals, J. D. Lee.

THE results of the election for the Ohio State University Chapter of the Sigma Xi Society was as follows:

*President*—C. S. Prosser, professor of geology.

*Vice-president*—John F. Lyman, professor of agricultural chemistry.

*Secretary*—W. M. Barrows, instructor in biology.

*Treasurer*—John A. Wilkinson, assistant professor of chemistry.

THE Minnesota Chapter of the Sigma Xi met on May 29 for its annual banquet and initiation of new members. At the same time researches of three of the initiates was presented as follows:

"A Successful Case of Applied Entomology," C. W. Howard.

"Parasitism in Rusts," E. C. Stakman.

"Sunlight as a Factor in Plant Metabolism," R. W. Thatcher.

At Minnesota, research is essential for the election to Sigma Xi.

DR. JAMES W. JOBLING, of Michael Reese Hospital, Chicago, Ills., gave the annual address before the Minnesota Pathological Society on May 20. His subject was "The Toxicity and Antigenetic Properties of the Cleavage Products of Bacterial Proteins."

PROFESSOR G. H. PARKER, of Harvard University, addressed the Brown Chapter of Sigma Xi, at the University Club, Providence, on May 28, on a "Biological Forecast."

PROFESSOR G. W. PIERCE, of Harvard University, has delivered three lectures on "Wireless Telegraphy and Wireless Telephony" before the student officers of the post-graduate department of the United States Naval Academy at Annapolis, Md.

A LARGE bronze mural tablet to the memory of the late Dr. John Herr Musser, professor of clinical surgery in the University of Pennsylvania, has been presented to the University Hospital. The tablet was designed by Dr. R. Tait McKenzie.

LORD AVEBURY, formerly Sir John Lubbock, distinguished for public services in many di-

rections, including a large number of contributions to natural science and books of popular interest, died on May 28, aged seventy-nine years.

DR. MAX THOMAS EDELMANN, professor of physics in the School of Technology of Munich, has died at the age of sixty-eight years.

DR. H. WEBER, professor of mathematics at Strassburg University, died on May 17, at seventy-one years of age.

M. ALFRED DE FOVILLE, permanent secretary of the Académie des Sciences Morales et Politiques, an eminent economist and statistician, has died at the age of seventy-one years.

THE death is announced of Friedrich Wilhelm Ristenpart, director of the Observatory at Santiago, Chili.

THE U. S. Civil Service Commission announces an examination for soil biochemists at salaries ranging from \$1,800 to \$2,200 a year, in the Bureau of Soils, Washington, D. C.

THE Canadian Medical Association will hold its forty-sixth annual meeting in London, Ontario, on June 24, under the presidency of Dr. H. A. McCallum.

THE American Medical Association will hold its sixty-fourth annual session at Minneapolis from June 17 to 20, under the presidency of Dr. John A. Witherspoon. The work of the meeting will be distributed among the following sections: The practise of medicine, surgery, obstetrics, gynecology and abdominal surgery, ophthalmology, laryngology, otology and rhinology, diseases of children, pharmacology and therapeutics, pathology and physiology, stomatology, nervous and mental diseases, dermatology, preventive medicine and public health, genito-urinary diseases, hospitals and orthopedic surgery.

A TIDAL observatory, the first of its kind in Great Britain, erected near the Castle, Dunbar, has been opened. One of the main objects of the observatory will be to afford a

means of examining local vertical movements of the coastline, if any occur, as recommended by the royal commission on coast erosion.

THE Nathan Lewis Hatfield prize of the College of Physicians of Philadelphia, amounting to \$500, will be awarded in 1916. The deed of trust requires that the prize shall be on a subject of general medicine, medical pathology or therapeutics, the treatment to embody original observations, or researches, or original deductions. Competition for the prize is open to the medical profession and men of science in the United States. The original of the successful essay becomes the property of the College of Physicians. All manuscripts must be sent by May 30, 1915, to the committee, which consists of William G. Spiller, M.D. (chairman), Allen J. Smith, M.D., and William Pepper, M.D.

AN association, called the Union Médicale Franco-Ibéro-Américaine, has, as we learn from the *British Medical Journal*, recently been formed in Paris for the purpose of uniting the doctors of the republics of Central and South America with Spanish and French physicians in a scientific alliance of Latin races. From the initial letters of its title it is called for shortness "Umfia." The president is Dr. L. Dartigues; the general secretary is Dr. Gaullier l'Hardy; the vice-presidents, Drs. Bandelac de Pariente (physician to the Spanish embassy in Paris), Manrique and Delaunay. Among the members of the honorary committee are the Spanish ambassador to the French republic; Professor Ortega Morejon, member of the Spanish Academy of Medicine; Dr. Pulido, senator of Spain; Dr. Risquez, sometime rector of the University of Caracas, together with the dean of the Paris Faculty, Professor Landouzy, and Professors Ch. Richet, F. Widal, A. Robin, Pozzi, Pierre Marie, Pinard, Legueu, Doléris and Bazy, and Dr. Roux, director of the Pasteur Institute. Membership is open to all doctors throughout the world who speak Spanish or Portuguese. At present there exist more than twenty autonomous nations of Spanish speech, and it is estimated that the language is spoken

by more than a hundred million persons. It is proposed to establish a Hispano-American Hospital, to arrange scientific tours and to make summaries of all medical papers written in Spanish available for members. The objects of the *Umfa* are to make its members known to each other, to establish relations, social and scientific, with the doctors of every country where Spanish is spoken; to establish an information bureau for Spanish or Portuguese doctors who go to Paris to pursue clinical work and research; to arrange courses of instruction, lectures, meetings, festivities and congresses, and to organize means of assistance to foreigners of Spanish-American origin settled in Paris who may be in need of help.

WE learn from *Nature* that the famous prehistoric camp, known as Maiden Castle, near Dorchester, has been, at the suggestion of King George, purchased by the Duchy of Cornwall, and will now be carefully preserved. The camp dates from Celtic times, and formed a shelter for cattle during tribal raids rather than a military fortress. Water was supplied from a neolithic dew-pond on the summit of the plateau, and the palisading kept at bay wolves and other enemies, while the cattle were left in charge of a few women and children. The cunningly arranged entrances to the camp supply a remarkable example of primitive methods of defence.

#### UNIVERSITY AND EDUCATIONAL NEWS

THE special state appropriation bills for the University of California, as signed by the governor, provide amounts as follows: support and maintenance of the university, \$400,000; agriculture (support and maintenance of all branches), \$700,000; New North Hall, \$400,000; impairment of income, \$62,000; replacement of buildings and equipment at Lick Observatory, \$50,000; university extension, \$50,000; Los Angeles medical department (support), \$20,000; Los Angeles medical department (new buildings), \$25,000; Scripps Institution for Biological Research, \$15,000;

printing, \$12,000; one dormitory at Davis, \$40,000; dining hall at Davis, \$10,000; classroom and library buildings at Davis, \$65,000; small buildings at Davis, \$20,000; 200 acres for experiment station in southern California, \$60,000; laboratory building for experiment station in southern California, \$100,000; residence, barns, etc., for experiment station in southern California, \$25,000; total special appropriations, \$2,054,000. To these appropriations there must be added the state university fund to be automatically appropriated during the coming two years for the support and maintenance of the university amounting in total to \$1,802,978. The grand total appropriated by the state of California for the University of California for the next biennium is therefore \$3,856,978.

YALE UNIVERSITY will receive \$475,000 from the estate of Dr. Francis Bacon, who died last year. The sum will be available for almost immediate use.

MRS. MARY EMERY has contributed \$125,000 to the Ohio-Miami Medical College of the University of Cincinnati for the endowment of a chair of pathology. A sum of about \$80,000 from the estate of Dr. Francis Brunning has also been received by the university, the income of which will be used for the endowment of a second chair.

THE general faculty of Oberlin College has voted to recommend to the trustees that this year all honorary degrees be omitted at commencement.

MR. KERR DUNCAN MACMILLAN, assistant professor of church history in the Princeton Theological Seminary, has been elected to the presidency of Wells College.

DR. JAMES H. WOODS has been promoted to be professor of philosophy at Harvard University.

DR. CHARLES AUGUSTUS TUTTLE, professor of political economy and political science at Wabash College, Crawfordsville, Ind., has been elected professor of economics and social science at Wesleyan University.

DR. J. ARGYLL CAMPBELL, junior assistant to Professor Schäfer at Edinburgh University, has been appointed professor of physiology in the University of Singapore.

W. DAWSON, M.A., D.Sc. (Agr.), has been appointed to succeed Mr. A. Henry as reader in forestry at Cambridge University. Mr. Dawson has held a similar position at Aberdeen University.

PROFESSOR STRASBURGER, of Breslau, has accepted the position of director of the newly-established medical policlinic and therapeutic course at Frankfort-on-the-Main, which are to be considered a department of the proposed university.

PROFESSOR KAISERLING, of Berlin, has accepted the appointment as successor of Professor Henke at the Cologne Institute of Pathology.

## DISCUSSION AND CORRESPONDENCE

### TYPES OF SPECIES IN BOTANICAL TAXONOMY

It is becoming more and more evident that only by the use of the method of types<sup>1</sup> can any stability be secured in taxonomy. In spite of a growing realization of this fact there has been no adequate appreciation on the part of botanists of the great advantages offered by plants over animals in the facilities they afford for the multiplication of type material.

#### *Primary Types*

Although the author of a new species usually has at his disposal several different specimens upon which he bases his description, nevertheless only a single twig or shoot together with any organs borne on it can be considered to be the true type specimen. It is not permissible to accept as parts of the type other twigs or stems, for it often happens that they were not collected from the plant that yielded the true type specimen and subsequent research may show them to belong

to a different variety or even to a different species. Experience has shown that the author of a species is far from infallible, and that to accept his verdict on this point may give rise to a complete misunderstanding of the species on the part of later investigators and cause endless confusion in the subsequent literature.

Even in case of dioecious or polymorphous plants where it is obviously impossible for a single specimen to represent all of the essential characters of the species, the twigs cut from different forms are not to be considered as parts of the type specimen. It is easy to see that where several species occur in the same region it is not always possible for the author of the species to be sure that the different sexes or castes<sup>2</sup> represented in the material at his disposal really belong to one and the same species. It is necessary to designate some one specimen as the type and to associate with it as paratypes additional specimens of the other sex or of the other castes that seem undoubtedly to belong to the same species. Usually the pistillate specimen will be designated as the type.<sup>3</sup>

Even in case of a number of specimens presumably cut from the same plant it is unsafe to consider more than one of them as the type since there is always the chance that two plants growing close together were not distinguished. Abnormalities or bud variations on the type plant might also be overlooked, particularly if the collector, not realizing that he was dealing with a new species, exercised no unusual care.

The type specimen is therefore unique, and can not exist in duplicate. Types are the

<sup>1</sup> Cook has discussed in some detail the various castes of plants having definitely specialized heterism (ropism). Cook, O. F., 1907, "Aspects of Kinetic Evolution," in *Proceed. Wash. Acad. Sci.*, 8: 369-378, February 13.

<sup>2</sup> The term allotype, although proposed for paleontological material, might very properly be applied to any paratype possessing some very important organ or distinctive feature not present in the type itself. Burling, Lancaster D., 1912, "The Nomenclature of Types," in *Journ. Wash. Acad. Sci.*, 2: 519-520, No. 21, December 19.

<sup>3</sup> Cook, O. F., 1898, "The Method of Types," in *SCIENCE* (N. S.), 8: 513-516, No. 193, October 14. Cook, O. F., 1900, "The Method of Types in Botanical Nomenclature," in *SCIENCE* (N. S.), 12: 475-481, No. 300, September 28.

most valuable possession of museums and constantly increase in value as years elapse. They should not be left in the herbarium with the ordinary specimens, but should be so mounted as to be protected from injury in handling\* and should be kept in fire-proof cases, if possible in a special room where they may be consulted in the presence of a custodian who can help to preserve all fragments of the type material.

The type plant from which the type specimen was secured has a far greater importance than a type animal. Very often additional specimens almost exactly duplicating the type can be secured from it. These are merotypes<sup>5</sup> and if used by the author of the species in drawing up the original description become paratypes as well. Carefully selected merotypes collected at the same time as the type specimen and used by the author as paratypes are, properly speaking, duplicate types, having practically the same value from a taxonomic standpoint as the type itself, and should receive the same treatment in museums.

If the original type is lost during the life of the author of the species it is often possible to secure substitute types collected from the very spot where the type was secured. It is sometimes possible to secure merotypes from the plant that yielded the original type. As a rule no such satisfactory substitute types can be obtained after the death of the author of the species.

Besides merotypes proper, cut from the type plant as it stands, it is often possible to secure specimens from its vegetatively propagated offspring. Such clonotypes,<sup>6</sup> as they have been called, may be secured from plants that

reproduce naturally by bulbs, offshoots, tubers, etc., as well as from those propagated artificially by grafts or cuttings. Clonotypes can thus be obtained in unlimited numbers and are usually only slightly less representative than merotypes proper.

Specimens taken from seedlings of the type plant have been called spermotypes. They are of interest in case of short-lived species too small to furnish many merotypes and unable to yield clonotypes. Such seedlings if compared with the type and found to agree with it in all essential characters yield spermotypes almost as representative as clonotypes or merotypes. Spermotypes of dioecious or polymorphic species have unusual value since the seeds obtained from the female plant that yielded the type specimen can usually be depended upon to reproduce the species unchanged, with of course both the constituent sexes or all the polymorphic forms represented among the seedlings.

#### *Reproduced Types*

Besides the additional material obtained through the subdivision of the type plant or by its propagation vegetatively or from seed there are other important means for the wide distribution of type material.

Photographs may be taken of the type specimens and, inasmuch as the camera is able to reproduce all the detail visible to the unaided eye and does it mechanically, these photographs,<sup>7</sup> as they have been called, are of much value, especially as they can be reproduced indefinitely.

Phototypes are rendered still more valuable if they can be supplemented by a fragment of the type taken from a position definitely marked on the photograph. Such specimens have been called clastotypes. They can have, of course, only a limited distribution, since very few fragments can be spared from a type specimen.

\*Kellerman, Maude, 1912, "A Method of Preserving Type Specimens," in *Journ. Wash. Acad. Sci.*, 2: 222-223, No. 9, May 4.

<sup>5</sup>Swingle, Walter T., 1912, "Merotypes as a Means of Multiplying Botanical Types," in *Journal Wash. Acad. Sci.*, 2: 220-222, No. 9, May 4.

<sup>6</sup>Swingle, Walter T., 1912, "Clastotypes, Clonotypes and Spermotypes, Means for Multiplying Botanical Type Material," in the *Journal Wash. Acad. Sci.*, 2: 337-339, No. 14, August 19.

<sup>7</sup>Kellerman, Maude, 1912, "Phototypes, Means for Wide Distribution of Type Material," in *Journal Wash. Acad. Sci.*, 2: 339-40, No. 13, August 19.

A representative merotype properly authenticated may be illustrated by nature prints, discovered by Auer and Worring and so beautifully applied by Ettingshausen and Pokorny,<sup>8</sup> whereby all the minute details of venation are shown in exact mechanical reproduction, and an indefinite number of copies can be made for distribution. This method, marvellous as it is, can not be used for the type itself, as the specimen may be destroyed or at least injured in the process of making the plate.<sup>9</sup>

Such a nature print, for which the term *piesmotype*<sup>10</sup> is suggested, is eminently adapted for the reproduction of an authentic merotype. This *piesmotype*, together with a phototype, gives an authentic, unbiased and very vivid picture of the type of the species.

Finally, in case of cones, nuts, or other organs showing relief sculpture, casts may be taken; these are the *plastotypes* of Schuchert.<sup>11</sup> They are probably of greatest value in reproducing types of fossil plants, although they can be made from almost any glabrous plant organ.

### *Syntypes and Paratypes*

If, as is usually the case, several specimens from distinct plants and often from different localities are used by the author in describing his species the type material belongs to one of two categories. Either the author did not

<sup>8</sup> Ettingshausen, C., and Pokorny, A., 1856, "Physiotypia plantarum austriacarum. Der Naturselfstdruck in seiner Anwendung auf die Gefäßpflanzen des österreichischen Kaiserstaates." F<sup>o</sup>, 5 vols., Wien.

<sup>9</sup> The thoroughly dry herbarium specimen is forced into a plate of soft lead by great pressure exerted by a slow-moving roller, then an electrotype is made in hard metal from the lead original and impressions are made from the electro as is done from an engraved copper plate.

<sup>10</sup> *Piesmotype* (πικρμός, pressure; τύπος, type); a picture printed from a plate bearing an imprint made by mechanical means from an authentic merotype.

<sup>11</sup> Schuchert, Charles, 1897, "What is a Type in Natural History," in *SCIENCE* (N. S.), 5: 636-640, No. 121, April 23.

directly or indirectly designate a type and therefore all the specimens are *syntypes*,<sup>12</sup> or a type was designated, in which case the other specimens studied by the author are *paratypes*.<sup>13</sup>

What are here called *syntypes* are also known as *cotypes*,<sup>14</sup> but unfortunately the latter word is also very commonly, though erroneously, used to designate *paratypes*. In earlier times when the author of a new species rarely designated a type all of the specimens were very properly known as *cotypes*. It was easy to continue to apply the name to the specimens, even when the author had designated one of them as a type. Such a practise leads to confusion and should be abandoned, and a more precise and definite terminology used.

Although *syntypes* are usually segregated sooner or later into a type (*lectotype*<sup>15</sup>) and *paratypes*, it is nevertheless important to avoid any confusion in type material such as is likely to result from using the term *cotype*. It would, indeed, be better to abandon altogether the word *cotype*.

The rules that have been formulated for the typification of species, particularly those given in the American code of botanical no-

<sup>12</sup> [Bather, F. A.], 1894, "Scientific Volapuk," in *Natural Science*, 4: 57, No. 23, January.

<sup>13</sup> "A *para-type* is a specimen belonging to the original series, but not the type, in cases where the author has himself selected a type. It should, however, be one of the specimens mentioned or enumerated in the original description." Thomas, Oldfield, 1893, "Suggestions for the More Definite Use of the Word 'Type' and its Compounds as Denoting Specimens of a Greater or Less Degree of Authenticity," in *Proc. Zool. Soc.*, 1893, p. 242, Pt. 2, No. 17, August 1.

<sup>14</sup> "A *cotype* is one of two or more specimens together forming the basis of a species, no type having been selected. No species would have both type and co-types, but either the former, or two or more of the latter." Thomas, Oldfield, l. c.

<sup>15</sup> Schuchert, Charles, in Merrill, Geo. P., 1905, *Catalogue of the Type and Figured Specimens of Fossils, Minerals, Rocks and Ores in the Department of Geology, United States National Museum*, Bull. 53, Part I., Fossil Invertebrates, p. 12.

menclature, suffice in very many cases to determine which of the syntypes is to be made the lectotype.<sup>18</sup>

### Supplementary Typical Material

Besides the type material proper there are the so-called supplementary types (plesiotypes) and typical specimens (topotypes, etc.) which have been treated in detail by Schuchert. These need not be considered here, as they are merely specimens judged, with more or less show of reason, to be like the type. Often, perhaps usually, they do not belong in the type collection at all.

To summarize briefly the different kinds of type material we have:

#### I. Type Material Proper

1. Primary types, specimens used by the author in describing a new species, including either (a) the true *type* (with its *clastotypes*) and *paratypes*, or (b) the *syntypes*.

2. Additional types, specimens taken from the type plant or from its offspring, including *merotypes*, *clonotypes* and *spermatypes*.

3. Substitute types, specimens selected as types when the type was not designated, including *lectotypes*.

4. Reproduced types, mechanical reproductions of types, including *phototypes*, *piesmotypes* and *plastotypes*.

#### II. Supplementary Typical Material

5. Supplementary types, specimens used as a basis for descriptions or figures of previously published species, *plesiotypes*.

6. Typical material, specimens (from the type locality if possible) considered to be like the type, *topotypes*, etc.

WALTER T. SWINGLE

#### MOSQUITOES POLLINATING ORCHIDS

EARLY in July, 1912, Miss Ada K. Dietz, who was doing research work in plant ecology at the University of Michigan Biological Station at Douglas Lake, told me that she had seen in Rees's Bog a mosquito bearing on its

head two small yellow masses that looked like pollen. I went to the bog and found many mosquitoes there. In a few minutes I had caught a half dozen or more, all of them females, bearing the yellow masses. On closer examination these proved to be pollinia of the orchid, *Habenaria obtusata* (Pursh.) which was at that time abundant in the bog and in full bloom. Most of the mosquitoes carried one pollinium, some had two or three, and one had four pollinia attached to its eyes.

This orchid is small, green and inconspicuous, but very similar in the structure of its flower to *Orchis mascula*, described by Darwin in his book on the "Fertilization of Orchids," and by Müller in "The Fertilization of Flowers." Also, the complex process of pollination as described in the last named book (p. 535) for *O. mascula* might apply almost unchanged for *H. obtusata* with mosquitoes instead of bees for the pollen-bearers.

I gathered a number of the plants and a few mosquitoes that were free from pollinia and put them together in a glass aquarium jar. In a few days the mosquitoes had removed most of the pollinia from the flowers and now bore them on their eyes exactly as had those caught outside.

I did not learn the name of the mosquito concerned. It was probably not *Culex pipiens*, which is mentioned by Müller as a visitor to the flowers of *Rhamnus Frangula*. So far as I know, this is the only case reported in which mosquitoes seem to be of primary importance as agents of pollination.

#### SCIENTIFIC BOOKS

*The New Realism: Cooperative Studies in Philosophy.* By E. B. HOLT, W. T. MARVIN, W. P. MONTAGUE, R. B. PERRY, W. B. PITKIN and E. G. SPAULDING. New York, The Macmillan Company. 1912.

*The World We Live In.* By GEORGE STUART FULLERTON. New York, The Macmillan Company. 1912.

The first of these contributions to philos-

<sup>18</sup> Arthur, J. C., et al, 1907, "American Code of Botanical Nomenclature," in *Bull. Torrey Bot. Club*, 34: 172-174, No. 4, April, published June 11.

ophy should have a somewhat exceptional interest for men of science. For it makes use of data drawn from the special sciences more than is the wont of philosophical books; it represents an attempt to introduce something more closely resembling the scientific method and temper into philosophical inquiry; and it is chiefly devoted to the establishment of a conclusion which, if accepted, would apparently necessitate the relinquishment of certain modes of thought and speech frequently used in the interpretation of the methods and results of scientific observation. In the spirit and procedure of the authors there is much that is both rare and laudable. Real, organized cooperation in philosophizing—the provisional segregation of definite questions, and an attempt to reach a collective answer to them by methods which have borne the test of open discussion at close quarters and of repetition by other inquirers—this is still a sadly unaccustomed practise among philosophers; there are even those who deem it impossible and of dubious desirability. Whatever else they have done, the six authors of "The New Realism" have in this matter set the philosophical world an example which it is to be hoped will be not only praised but imitated. Nor is it only in their cooperation that they have carried over the temper of science into the business of the philosopher. The book for the most part is singularly free from those *arrière-pensées* which often vitiate, even though they enrich and make more humanly interesting, philosophic reflection. There is almost no trace of the desire to edify, no great solicitude as to the immediate bearing of their results upon "life," no tendency to confuse philosophy with either poetry or preaching. The writers seem desirous merely of reaching a verifiable conclusion upon a specific issue. With complete intellectual detachment they can not, indeed, quite be credited; they have, after all, a *parti pris*, and at least one of the six writes much in the style and spirit of the special pleader. But since they have a common cause to sustain, the openness with which they acknowledge its initial difficulties and disclose their inability

to agree upon a common solution of those difficulties, is the more admirable. One's admiration would, indeed, have been still greater if this had led to an actual suspension of judgment upon the main issue, as the final result of the cooperative effort—which, as will appear, is the result towards which, at most, the course of the argument would seem to point. But this, perhaps, is more than it would be reasonable to expect. Even as it is the book is an almost unique example of a genuine and persistent attempt at close thinking *together*—at a literally "dialectic" process—on the part of a considerable number of philosophers, of whom none stands in the relation of master to the others.

The point in the "new realism" which constitutes both its novelty and its chief significance for natural science is, not its realism, but its doctrine about consciousness. For that doctrine, if accepted, entails the abandonment of certain conceptions still extensively used by science as well as by common sense. It has been, moreover, the generating principle of the whole theory, from which all of its principal conclusions and most of its characteristic difficulties have arisen. It is the more important to recall this fact because, while this theory of consciousness clearly underlies much of the reasoning in the volume, it is not altogether definitely and connectedly stated here (though it has been so stated in previous writings of some of the group), and it seems at times to be forgotten altogether.

The doctrine in question is this: that what is commonly called "consciousness" is simply a particular mode of relation; and that it is an "external" relation, *i. e.*, one which does not constitute or in any way alter the terms which at any time happen to enter into that relation. From this doctrine follow directly the two essential articles in the new realism's account of the nature of the transaction called sense-perception—its affirmation, at once, of the "independence" and of the "immanence" of the object perceived. Given the conception of consciousness as merely an otiose relation among items totally unaffected thereby, and

the object necessarily must be independent; for such a relation is not a thing upon which anything *could* depend. No less obviously must the object be immanent; *i. e.*, must at the time of perception be "numerically" and in all other respects identical with the percept. For there is nothing in an external relation which could produce duplicates or "images" of the terms related. Thus the root-doctrine of this new philosophy is "the relational theory of consciousness," which branches out into the two derivative doctrines of realism and epistemological monism (*i. e.*, the doctrine that object and idea or percept are one identical entity). Not only does it produce these secondary conclusions; it apparently provides their chief support. I, at least, am unable to find in the volume much *positive* argument (as distinct from proofs of the inconclusiveness of certain arguments of idealism and dualism) for the object's independence and immanence, except deductions from the relational theory of consciousness. Upon the validity of this theory, then, the constructive part of the new realism depends. I shall accordingly limit the present examination of this collection of reasonings to two questions: (1) What positive reasons are offered for the opinion that consciousness is merely an external relation? (2) How do the new realists meet the usual arguments—not of idealism, but of common sense—for the view that consciousness can not possibly in all cases be an external relation, that, in other words, *some* content of consciousness must be regarded as existing only in and by means of consciousness?

1. With regard to the first point, one must first of all complain that the relational theory of consciousness is left, in two important respects, in great obscurity. It still remains difficult to determine just *what kind* of relation *to* what, the consciousness-relation is supposed to be. So far as the authors approach definiteness upon this, they also seem to diverge from one another. But I do not here wish to dwell upon this consideration. More serious is the uncertainty in which the reader is left with respect to another question. Is

consciousness held to be *wholly and in all cases* non-constitutive of the content that is in consciousness? Does the new realism mean to reject the notion of "purely subjective existence" *in toto*, and to maintain that all experiences are equally independent and objective, that only things, and not thoughts, exist at all? For Perry, the answer appears to be negative; this view, he observes, "is not part of realism." "Values," "interests," "higher complexes, such as history, society, life or reflective thought," all these *are* "dependent on consciousness." Independence, then, is not universally predicated of things experienced; all that is maintained is that "*in certain notable cases, at least*, things are none the less independent for being perceived." But this is an immense and fatal qualification of the relational theory. For if consciousness is *capable* of having content that depends upon it for existence, that is purely its own, one obviously can not argue from a general incapacity of consciousness to constitute its own content to the conclusion that the objects of perception are independent, etc. The nerve of the main positive argument for both realism and epistemological monism is thus cut. If consciousness is in some cases an external and in some cases a constitutive "relation," it becomes necessary to adduce specific empirical evidence to show that in each and every case of perception it is of the former sort. And no such evidence is offered. Strictly empirical evidence, indeed, it is manifestly impossible to offer; since things are always experienced in the consciousness-relation, experience, at least, can not testify to their independence of and externality to that relation. If, then, we take the external-relation theory in Perry's sense—as meaning merely that consciousness *may be* an external relation—we must admit the theory to be true. There are, doubtless, external relations; and it is conceivable that "being in consciousness" may sometimes be one of them. But from this "may-be" no proof of the neo-realistic theory of perception can be drawn; yet no other positive proof is given.

Others of the group, therefore, avoid

Perry's damaging concession. Pitkin, for example, declares that "the realist can not count his case won" until he has shown "the complete independence of all things thought of." He feels obliged, therefore, to hold that even hallucinatory objects, and errors of all sorts, are "no less independent of cognition than true propositions are." That secondary qualities, illusory presentations, and the like, can all be, without contradiction, conceived as objective and independent, Montague, Holt and Pitkin alike are concerned to show; and the only imaginable reason for their undertaking to justify this paradox is an acceptance of the view that consciousness is *in no case* constitutive of any perceived content, that it is always and absolutely a relation which does not create its terms nor modify their other relations.

But for this more rigorous construction of the relational theory, what evidence is offered? It, if established, would prove neo-realism's case, as I have admitted; but by what argument is this all-important premise itself to be established? Of general and positive arguments for it there are, so far as I can see, none in the book. Direct empirical evidence is, once more, unattainable, in the nature of the case, and is not attempted. What we are given is merely a series of attempts to show that the theory is not absurd, that the general and unqualified assertion that no perceived datum ever does or can depend upon its relation to a perceiver for its existence or any of its attributes or its other relations, is not the extravagance which it at first appears to be. Even if these attempts be regarded as successful, they could not, by a rigorous logician, be regarded as establishing the conclusion desired. There are many propositions which are not absurd which are also not true. The battle for the relational view of consciousness can hardly be won by purely defensive tactics. But are even those tactics successful? To this question we must now turn.

2. Science, I have said, as well as popular thought, is still, as a rule, accustomed to think of some of the content of experience as existing "merely subjectively." The whole

distinction between appearance and reality—in the ordinary, empirical sense—which science has found so indispensable has usually taken the form of the supposition that certain data of perception,—*e. g.*, the secondary qualities of matter, illusions, dreams, hallucinations—can be explained away as having their being only in "minds" and by virtue of minds, as *being* only in so far as, and only in the sense that, somebody is conscious of them. This, then, is the way of thinking and of speaking which the new realism (in so far as it treats its relational theory of consciousness as a universal proposition) invites us to give up. It therefore proposes a radical revision of widely current preconceptions. The important question to raise concerning it, then, is this: Can we, while maintaining realism, *completely* dispense with the idea of "subjective appearance," of "mental representations" of objects, can we hold without self-contradiction that what things seem they also are, and that the entity present "in consciousness" whenever we perceive or think of an object is just the original, *simon-pure* object itself, untransformed, unduplicated and untransposed?

That their doctrine stands or falls with the answer to this question, the authors very frankly acknowledge. "The crucial problem," says Pitkin, "for the new realism is the problem of error (in all forms). And the acutest critics" of the doctrine "urge that its fatal flaw is the acceptance of the full 'objective' nature of illusions and errors and its simultaneous refusal to put illusory objects, with all their colors, shapes and behaviors, identically in the very space and time in which they immediately belong. If the charge is true it is deadly." To meeting this type of objection the papers of Montague, Holt and Pitkin are chiefly devoted.

Unfortunately space is lacking here for an adequate analysis of these highly ingenious and rather involved pieces of argumentation; that examination must be attempted elsewhere. For the present it must suffice to observe that these three writers are unable to agree upon any one "solution of the problem of error" in terms which shall be consistent with

their general doctrine. Each repudiates the solutions of the others; each, therefore, from the point of view of the others, has no logical right to be a new realist, since he fails (in their eyes) to meet satisfactorily an objection which admittedly must be met before the new realism can be regarded as tenable. So long as these spokesmen of a common cause, after prolonged conference and discussion *inter se*, are unable to convince one another, no one of them will feel it surprising that he fails to convince his readers. Nor is this the worst of the situation. In an appendix definite refutations are offered of all three solutions; Montague refutes Holt and Pitkin, and Pitkin refutes Montague. This does infinite credit to their candor and philosophical good faith; but it leaves their doctrine in a parlous state. For both appear to me to be perfectly good refutations; so that at the end of the volume the formal outcome of the triple effort to solve the problem of error and meet the opponent's argument from hallucinations is literally *nil*.  $3-1-1-1=0$ .

Thus far, then, I do not think it can be said that these vigorous innovators have demonstrated that consciousness does not exist save as an irrelevant relation between objects always and absolutely uncolored by its presence; or that the convenient supposition that some things in consciousness exist solely therein, as "subjective appearances," must be abandoned. But failing a proof of this, the new realism, as a whole, is lacking in logical substructure.

In the interest of a discussion of this main issue, I have been obliged to omit mention hitherto of two carefully reasoned papers which are less closely related to that issue: that of Marvin on "The Emancipation of Metaphysics from Epistemology" and that of Spaulding, "A Defense of Analysis." These both reward the reading irrespective of one's interest, or lack of it, in the new realism. Spaulding's paper contains an effective analysis of some of the confusions of Bergson and other anti-intellectualists.

Professor Fullerton's book also is a defense of "the new realism," but apparently not of

the same new realism. We shall soon be obliged to distinguish the various claimants of the name by numerals. Just how Fullerton's view is logically related to that of the authors already discussed, it is a matter of some difficulty to determine. He sometimes seems plainly to reject the relational conception of consciousness and the resultant epistemological monism. "The world," we are told, "is phenomenon; it is in a sense a function of the creature perceiving the world. Each gazes upon his own world." There is "a whole series of phenomenal worlds differing more or less from one another. Only one of these is ours and is known by us directly" (pp. 106-107). There are apparently some things which "should be regarded as existing only in the mind" (p. 129), which are "internal and subjective" (p. 131). Yet we are also told that we are "as directly conscious of external things as we are of anything whatever," and that "we may with a clear conscience accept as external the things we actually perceive, with just the qualities and relations which we perceive them to have" (p. 149). Thus even the secondary qualities are "external" and in no sense subjective (Ch. X.). We do not perceive images of objects, but the objects themselves. Even so qualified a form of the representational theory of perception as Strong's "substitutionalism" is rejected (p. 158). Thus, so far as normal perception is concerned, Fullerton seems first to deny and then to adopt the theory of the immediacy or "immanence" of the real object in perception. The final criterion, however, of any writer's attitude towards the view that consciousness is an external relation lies in his explanation of the facts of error and hallucination. Is the hallucinatory object a function of the perceptual process or is it, too, "external" and independent thereof? Does the long-extinct star "really exist" at the moment when I belatedly perceive it? If not, does not the star actually perceived subsist at the moment in dependence upon the consciousness of that moment? Unfortunately, Fullerton, while he raises these questions, does not meet them in a way which unequivocally de-

finer his attitude to the relational theory. He observes (pp. 156-163) that our errors are largely mere omissions and not creations; that even illusions "deceive no well-informed person"; and that "were men sufficiently well-informed, and were such experiences sufficiently common, there would in no case be the shadow of an illusion," which seems to mean only that if there were no illusions there would be no illusions. The fact remains that illusions, hallucinations and dreams occur; and the question is whether (as some neo-realists hold) the content presented in these can be said to exist in real, objective space, at the time of its presence in consciousness, and whether there is any justification for, or meaning in, calling it "independent" of consciousness. To this question, with which the other new realists so laboriously deal, Fullerton, so far as I can see, gives no entirely plain answer; and it is for this reason that the relation of his realism to theirs remains, at the most significant point of all, obscure. I take it, however, that he does *not* view consciousness as an absolutely functionless relation, and that he would reject the paradox of the objectivity of the illusory.

Assuming this to be his meaning, Fullerton must be understood to regard some content of perception as purely mental, or subjective, and some as wholly objective and independent. The further question remains: Where, and by what criterion, shall we draw the line between the two? Patient and subtle as are Fullerton's reasonings upon this point, I do not find them altogether clear or convincing. His desire, evidently, is to make the realm of the subjective a very little one; hence his exclusion from it even of the secondary qualities, and his apparent reduction of it to the hallucinatory and imaginary merely. But his reasons for drawing the line where he does appear to me blurred through a failure to give and adhere to a single, clear definition of "external" and "objective." In a general way one gathers that (pp. 111-115) things and qualities are external, in the proper sense, when they do not involve a "relation to our sense-organs," when I "can account for them

without referring to the relation of my body to them." But this throws little light upon the subject. How am I to know when data which are obviously mediated through my sense-organs involve no relation thereto? When (as in the case of color) specific variations in my sense-organs are uniformly accompanied by specific variations in the qualities which appear in consciousness, are not the latter, in accordance with the definition given, "internal" or mental? But in that case, what becomes of the proof of the externality of color-qualities? Does Fullerton, then, mean that anything is external which without contradiction can be *conceived* as existing without involving the idea of my body? If this is what is meant, one must still object that there are familiar arguments which seem to show that most of the perceived qualities which one object presents to different percipients *are* reciprocally contradictory, so long as the qualities are regarded as inhering independently in the object by itself, and not as functions of its diverse relations to those percipients. These points not being satisfactorily dealt with, Fullerton's realistic construction fails of complete definiteness of outline and consequently of cogency.

A noteworthy part of the book is the interpretation of Kant as the "first great modern realist" (Chaps. V.-VII.); this view is not new, but it has never, perhaps, been so forcibly presented. The most brilliant chapters in the volume are the critical ones. The passages on absolute idealism and on pragmatism are delightfully witty, yet eminently searching, examples of philosophic satire. The latter, I think, is less than just to some aspects of pragmatism; but the former (Chaps. XIII.-XV.) is a masterpiece in its kind.

ARTHUR O. LOVEJOY

THE JOHNS HOPKINS UNIVERSITY

*Handbuch der Entomologie.* Herausgegeben von Professor Dr. CHR. SCHRÖDER. Jena, Gustav Fischer, 1913.

For the past twenty years Kolbe's "Einleitung" has been the best known German text-book on entomology. Now Dr. Schröder

(editor of the *Zeitschr. f. wissenschaftl. Insektenbiologie*) has undertaken to issue a more extensive work. It is significant of the increasing specialization in entomology that this new work is not the product of one author, but of eleven. It is divided into three parts: Volume I. is on the Anatomy, Embryology, Morphology, and Metamorphosis, and is prepared by Dr. C. Börner, Professor P. Deegener, Dr. J. Gross, and Dr. O. Prochnow. Volume II. will treat of the Habits, Distribution, Economic, and Experimental Entomology, and will be written by Dr. Schröder, Dr. K. Eckstein, Dr. O. Heineck, Dr. K. Holdhaus, Dr. L. Reh, and Dr. H. Rübsaamen. Volume III. will consider Paleontomology, Phylogeny, and Systematics, and is to be prepared by Dr. A. Handlirsch. The portions now issued (three parts of Volume I.) are almost wholly by Dr. Deegener. Chapter I. is on the skin (including color, scales, skin-glands, scent-glands, wax-glands, etc.) with an appendix on the sound organs; Chapter II. treats the nervous system (especially the larger ganglia); Chapter III. the sense-organs, largely histological. In this chapter are various minor errors; the great family Capsidæ is not mentioned under Heteroptera as being without ocelli, the Panorpatæ are stated to have three ocelli, although on a previous page the genus *Boreus* is correctly stated to be without ocelli, and the various cases of ocelli in Coleoptera are unmentioned. The various sense-organs of unknown purpose (pseudocelli, abdominal organs of moths, post-antennal organs) are considered, as well as the supposed correlation or rather complementary development between the eyes and the antennæ. Chapter IV. considers the alimentary canal and its appendages (salivary glands, malpighian glands, anal glands) and is very complete, as Dr. Deegener is particularly interested in this matter. Chapter V. is on the respiratory organs, and is rather one-sided, most attention being given to respiration in aquatic insects and in parasites. Chapter VI. treats of the circulation, blood, heart, the specific heat of insects, fat-bodies, light-organs (rather briefly) and œnocytes.

Chapter VII. relates to the endoskeleton and muscles. The muscular system of the imago of *Dystiscus* (as given by Bauer) is taken as typical, with but little comparison to other insects or larvæ. Only a brief summary is given of the endoskeleton, and brief treatment of muscular contraction, attachments of muscles, and muscular power of insects.

The most useful feature of the work is the long bibliographies at the end of each chapter. Although not by any means complete (American references often lacking) these lists furnish references that are difficult to secure but essential to any one studying these subjects. In fact, so useful is this new "Handbuch" that we hope a group of our entomologists will plan an American work on the same general lines.

NATHAN BANKS

#### TRIALS AND TROPISMS

##### 1

SOME years ago<sup>1</sup> I attempted an analysis of the facts grouped under the familiar but apparently confusing term "tropism theory." In the light of my experience I found myself seriously questioning the validity of a view that had just been published by Jennings in his well-known book, "The Behavior of the Lower Organisms." The issue was essentially this: whether tropisms are developed through selection from overproduced movements by means of the method of trial, or whether they are primary responses in the same sense that these overproduced movements are, and not, therefore, products of a process of selection as suggested.

Jennings soon found opportunity to reply to my objections as well as to those of other critics, notably Loeb and Parker. His reply, however, does not appear to have convinced them, for they have both taken issue since with his conception of the nature of tropic reactions. And though, up to the present, I have not thought it either necessary or desirable to add my own misgivings to a rapidly

<sup>1</sup>"The Method of Trial and the Tropism Hypothesis," SCIENCE, N. S., XXVI., pp. 313-23, September 6, 1907.

growing controversy, I too have failed to be convinced. Controversies fatten on misunderstandings. There is evidence that this one has been no exception to the rule. Some of it may be found in a recent book by Mast<sup>2</sup> and in a review and reply<sup>3</sup> that have since appeared. Accordingly, silence might seem to be the better part. Nevertheless, I am tempted to brave the possibility of further difficulty by accepting what seems to be a reasonable chance of focusing attention more sharply than before on the issue raised in my former paper.

It will be my endeavor, then, to show why the view that tropic reactions are developed through selection of overproduced or trial movements is unsatisfactory. And I shall attempt to do this by calling attention to certain relations between the structure and behavior of non-symmetrical and bilaterally symmetrical organisms that have heretofore met with much scantier consideration than, in my opinion, they deserve. Let me refer first of all to the behavior of the non-symmetrical flagellate *Euglena*.

## II

*Euglena*, as is well known, is a non-symmetrical unicellular organism, with a single non-symmetrically placed photoreceptive region near the gullet, and swims in a spiral path by means of a flagellum, or, in the absence of the latter, assumes a crawling habit that is accompanied by a side-to-side oscillation suggesting the spiral swimming of the flagellated form.

I have been very much impressed by Mast's account of the orientation of the crawling *Euglena* to light. It appears that the organism, crawling in a path perpendicular to a beam of light, on entering the beam executes a turning movement toward the source of light; that this turning movement is accomplished by a series of sharp reactions, defined by a bending of the body away from the source of light; that each reaction follows an

abrupt change in intensity of light falling on the photoreceptive region; and that these abrupt changes are connected with the oscillation of the organism from side to side, leading to an intermittent presentation of the photoreceptor to the light in a position effective for stimulation.

Few will deny that constant stimulation plays no obvious rôle here. But many, I am sure, will not fail to be impressed with certain elements of similarity in structure and behavior between *Euglena* and various bilaterally symmetrical organisms with one of a symmetrical pair of eyes blinded. And just here appears a point that has not been always clearly apprehended by the author of "Light and the Behavior of Organisms." Somehow Mast has obtained from my former paper the impression that I evidently consider "that orientation [in *Euglena*] is due to the local effect of unequal stimulation of symmetrically situated points on the body"—and yet do not "explain where the symmetrically located points which are subject to local stimulation are situated in *Euglena*." I have looked carefully over my paper since this statement came to my notice, but have not been able to find any attempt to explain the orientation of *Euglena* on any such basis. That was perhaps a result to be expected, as I had not been conscious of an attempt so to explain the orientation of *Euglena* or any other non-symmetrical organism. Of the symmetrical points to which "it is evident" I refer, I frankly confess my ignorance. Nor do I feel any more hopeful than Mast himself of a successful issue to the most exhaustive search for them. Our reasons for this attitude of mind, however, do not coincide. For mine, the reader is referred to that suggestive resemblance between the structure and behavior of non-symmetrical organisms and symmetrical organisms non-symmetrically stimulated to which I would again call attention.

## III

Let us imagine *Euglena* crawling horizontally along a definite axis of locomotion, directly toward a source of light. At successive

<sup>2</sup>"Light and the Behavior of Organisms," New York, 1911.

<sup>3</sup>Parker, *Jour. An. Beh.*, Vol. I., 1911, p. 461; and Mast, *ibid.*, II., p. 209.

moments it comes to lie in different positions, in all of which the single photoreceptor is at the same distance from the axis, and in some of which it occupies positions that—if the forward movement be for the moment disregarded—are symmetrically placed with reference to a plane passing through the axis of locomotion and perpendicular to the substratum. Let us now compare two such symmetrical images of *Euglena* with a bilaterally symmetrical animal, with paired eyes, moving directly toward a source of light. In *Euglena* the single photoreceptor is now on the left, now on the right of the plane of symmetry. In the other organisms, the two photoreceptors are permanently fixed, and one on each side of that plane.

Now *Euglena* swerves toward the light only when it is in such a position that the photoreceptor when on one side of the plane of symmetry receives light at an angle differing from that at which it receives light from the same source when occupying a symmetrical position on the other side of the plane. Just so, according to all varieties of the tropism theory with which I am acquainted, various bilateral organisms swerve toward the light when their eyes, symmetrically placed on either side of the median plane of the body, receive light from a single source at different angles. Expressed in another way, this means that the eyes under such conditions are subjected to different effective light intensities. The very mechanism, then, which has long been held by advocates of the tropism theory to account for the definite, errorless turning movements of bilateral heliotropic organisms toward or away from light, is the mechanism that Mast has shown to be accountable for the heliotropic orientation of the non-symmetrical *Euglena*. If this be the case, it seems evident that, whether or not the separate reactions of *Euglena* whenever its photoreceptor is effectively presented to the light are to be regarded as overproduced movements that may resemble trials, the definitely directive reactions of bilateral animals to light have not been developed by any process of selection based on such movements.

## IV

It remains to consider the possibilities of such a mechanism for producing the delicately accurate heliotropic adjustments of some organisms; as well as the relation between pronounced shock reactions with no obvious relation to the direction of locomotion, and the definite errorless turning movements ordinarily referred to as tropic reactions.

Mast\* says of the orientation of *Euglena* in light from two sources:

When the light from the two glowers was equal and the *Euglena* positive, they moved in a general way toward a point midway between the glowers. But when it was unequal, they moved toward a point nearer the source from which the more intense light came. . . . This experiment is particularly striking if the glower on the track is gradually moved from a position in which the light intensity from it is much lower than that from the stationary glower to a position in which it is much higher. Under such conditions one can clearly see these organisms, especially the free swimming forms, gradually change their direction of motion through an angle of nearly 90°.

I gather from this description that changes in intensity are followed by reactions that vary with the degree of change. If this be true it may well account for the very slight variations which bilaterally symmetrical heliotropic organisms make from a straight course toward a source of light, and the precision with which such variations are corrected.

Further evidence of this sort is obtained from Fig. 13, p. 96, where, if the reactions are to be considered accurate in detail as drawn, it is seen that the orienting contractions of *Euglena* vary in magnitude as the path of the organism inclines more and more toward the source of light.

Similarly, Jennings\* describes the avoiding reaction of the free swimming *Euglena* in the following terms:

The *Euglenæ* are swimming about at random in a diffuse light, when a stronger light is allowed to fall upon them from one side. Thereupon the for-

\*"Light and the Behavior of the Lower Organisms," p. 86.

\*"Behavior of the Lower Organisms," p. 138.

ward movement becomes slower and the *Euglena* begin to swerve farther than usual toward the dorsal side. Thus the spiral path becomes wider and the anterior end swings about in a larger circle and is pointed successively in many different directions. In some part of its swinging in a circle the anterior end of course becomes directed more nearly toward the light; thereupon the amount of swinging decreases, so that the *Euglena* tends to retain a certain position so reached. In other parts of the swinging in a circle the anterior end becomes less exposed to the light; thereupon the swaying increases, so that the organism does not retain this position but swings to another. The result is that in its spiral course it successively swerves strongly toward the source of light, then slightly away from it, until by a continuation of this process the anterior end is directed toward the light. In this position it swims forward.

Figs. 91 and 92, p. 135, show variations in the severity of the reaction, the second figure representing but a very slight widening of the narrow spiral in which the organism has been swimming. Fig. 93, p. 139, represents the path of a *Euglena* executing a turn of 180° by a series of similar slight widenings of the spiral.

From such evidence it would seem that the motor reflexes of *Euglena* appear in varying degrees that shade more or less gradually into each other as the strength of stimulation varies. This admirably meets the requirements of a "tropism theory" that is expected to account for the gradual but definite and errorless turning movements executed by so many bilaterally symmetrical organisms in orienting themselves with respect to a source of light.

These considerations inclined me to the view that in bilaterally symmetrical organisms the shock reactions that have no obvious connection with orientation to a stimulus and are produced by *sudden changes in intensity* of light may occupy one end of a series at the other end of which are the very small reactions by means of which the tropic turning movement is achieved. In that case the difference in effect on orientation of these extreme cases would not indicate any fundamental difference in mechanisms governing them, but rather a

pronounced difference in the magnitude of the responses to stimuli of different intensities.

Recently, however, my attention has been called to new evidence, shortly to be published by my friend, Dr. F. W. Bancroft, that in *Euglena* the mechanisms of the shock reaction and the tropic reaction are distinct. How general this observation may prove to be is not now certain. But in any case, the shock reaction can hardly be said to occupy the position of a prototype from which trialless heliotropic turning movements have been derived by any process of selection.

HARRY BEAL TORREY

REED COLLEGE,  
PORTLAND, OREGON,  
January 9, 1913

#### AN AID TO STUDENTS

THE Academy of Natural Sciences of Philadelphia has published, as part of the aftermath of the brilliant centenary celebration of last year, an index to its publications from the first volume of the *Journal* issued in 1817 to the conclusion of the sixty-second volume of the *Proceedings* completed in 1911, making a total of eighty-three volumes. The portly index comprises 1,433 octavo pages and is divided into two sections. The first contains the titles of all the contributions to the series, arranged alphabetically under the names of the authors, and ranges from brief paragraph reports of the communications made verbally before the meetings of the academy to the classic quarto volume by Joseph Leidy on the extinct mammalian fauna of Dakota and Nebraska, and the beautiful monographs on the burial mounds of the south by Clarence B. Moore.

The second section is composed of an alphabetical arrangement, from *aalensis* to *Zythia*, of the names of every species, genus, and family described or referred to in the several volumes. It is estimated that there are about 124,600 such entries in the list and some idea of the labor involved in its preparation and arrangement may be had from the fact that the original entries under the letter P numbered 19,500, under S 16,650 and under T 10,300.

These were, of course, condensed in the arrangement, all the page references to a given name being placed under a single entry so that the printed result is much curtailed.

During the first five years of the academy's life it maintained a sort of chrysalis existence without much communication with the outside world. Of the six men who attended the initial meeting but one, the Dutchman Gerard Troost, later elected the first president, had any scientific training. At the next meeting Thomas Say was "adopted" by the others as one of the founders and he has since been regarded as one of the seven to whom the academy owes its existence. The communications to the meetings were at first confined almost solely to selections from Rees's Encyclopedia and certain text-books of science, but original observations soon became more frequent and by 1817 a sufficient amount of such material was in possession of the society to warrant the belief that an avenue of publication would be desirable. Through the interest and zeal of William Maclure, a Scotch philanthropist, the first number of the *Journal* was placed before the meeting held May 20, 1817. The volume contained contributions from Chas. A. Lesueur, Geo. Ord, Thomas Say, Thomas Nuttall, and William Maclure. Its interest and value were much enhanced by the beautiful engravings by Lesueur. It was at the time the only avenue of communication with the scientific world possessed by the working naturalists of America.

This series staggered on with intervals of quiescence until 1842, when it was decided that the *Proceedings*, which had been begun the previous year for the purpose of giving prompter publicity to the current business of the academy, supplied all that could be secured by an octavo publication.

To provide for papers requiring more elaborate illustrations than could be supplied in the octavo form, a quarto journal was started in 1847 and has been continued to the present time, the superb fifteenth volume having been published last December as the chief memento of the celebration held in March. Inciden-

tally it may be mentioned that the prompt issue of that volume, within nine months of the event it records, has been regarded all over the world as a record-breaking achievement. The illustrations to the quarto series were from the first of a high order of artistic merit. Special mention may be made of the colored illustrations of Cassin's birds, supplied by the liberality of Thomas B. Wilson; the really beautiful lithographs by Ibbotson of Isaac Lea's Melanians and Unios; and more recently the superb chromoplates of prehistoric pottery furnished by Mr. Clarence B. Moore in illustration of his monographs.

Access to the scientific contents of the eighty-three volumes, constituting one of the most important agencies in the advancement of science, will be greatly facilitated by the issue of the index which will undoubtedly be highly valued by students.

A few pages are devoted to a record of the time of publication of the several parts and volumes. The minutes, correspondence, and accessions lists of the academy were consulted to determine as many such dates as possible, and it is to be regretted that the result is not complete, the requisite data not being at hand, after the most careful search, to make it so. As far as the record goes, however, it will establish dates of publication of many researches of the first importance and help to determine many questions of priority, a matter to which the working naturalist is apt to attach much more importance than do those who value results without caring greatly as to who attains them.

#### SPECIAL ARTICLES

##### FACTORS INFLUENCING THE SURVIVAL OF BACTERIA AT TEMPERATURES IN THE VICINITY OF THE FREEZING POINT OF WATER<sup>1</sup>

It has been held by some bacteriologists that, while temperatures about the freezing point of water are less destructive of bacterial life than those about the boiling point, low temperatures are not only unfavorable to the growth and multiplication of bacteria, but

<sup>1</sup> Preliminary communication.

also to their prolonged existence. Prudden's experiments (1887) with water suspensions of a staphylococcus, in tubes greased to prevent crystallization at the temperatures employed (15–25° F.), led him to believe that at the same temperature the destruction of bacteria, due to cold, was greater when the water did not freeze, than when it did. Park, however, made similar experiments (1900) with *B. typhosus* and found that at the same temperature the reduction was 30 per cent. less in water remaining liquid for three days than where the water was frozen for the same length of time. Park further cites an experiment upon the freezing of typhoid bacilli in which 50 per cent. to 70 per cent. are killed "at the time," not more than 10 per cent. surviving after one week and 1 per cent. after four weeks, while Sedgwick and Winslow, after a careful review of the literature and many experiments, came to the conclusion that there is "during the first half hour of freezing a heavy reduction . . . amounting to perhaps 50 per cent. After this brief period of sudden but uncertain 'reduction' the destruction of the germs proceeds pretty regularly as a function of the time." Prescott and Winslow in their "Water Bacteriology" remark (p. 17) that "Temperature has a direct relation to bacterial life, and the number of parasitic bacteria at least may be quickly lessened by the action of cold." These conclusions are supported by the fact that ice, and especially old ice, even when formed from polluted sources, is very low in bacterial life.

On the other hand, it has gradually become known that various frozen foods, such as ice cream, frozen meat and frozen milk, often contain very large numbers of living bacteria, and this, too, even when kept for a long time, so that a serious contradiction seems here to exist between theory and fact. To this contradiction my attention was first drawn some two years ago during bacteriological studies of frozen eggs, and especially by the fact that such eggs, even after an exposure of many months to a temperature of 0° F., still contained millions of living bacteria. Obviously

it was no longer possible to hold that either mere cold or time is in and of itself necessarily destructive of bacterial life; and in the hope of bringing theory more clearly into harmony with experience I have within the last year made numerous experiments calculated to throw further light upon the general behavior of bacteria at temperatures about the freezing point of water.

Thus far I have worked almost exclusively with a single species, *B. coli*, which, as is well known, thrives at various moderate temperatures and especially at the blood heat. I have employed chiefly a 24-hour agar growth suspended in water, in physiological salt solution, in various dilutions of fat-free milk, in various mixtures of pure glycerine and water, and in solutions of cane sugar and of commercial glucose. In some cases freezing was done directly in test tubes; in other cases in an ice cream freezer with the formation of an ice "mush" or magma. By the courtesy of the Quincy Market Cold Storage and Warehouse Company of Boston I have been able to hold the suspensions thus frozen at temperatures as low as zero F. for periods of from four to eight months. The experiments are still in progress and some of them may be extended over a term of years.

The following is a brief summary of results:

I. When *B. coli* are frozen in Boston tap water (in test tubes) as solid ice, and held at –20° C., only a fraction of one per cent. of the original number remain alive at the end of five days. Storage of a few weeks results in complete destruction of the bacteria. These results confirm those of Sedgwick and Winslow.

II. When *B. coli* are frozen in Boston tap water not solidly, but as a water ice or sherbet is frozen, and held in this condition at –20° C., a large percentage remain alive for many months.

III. When *B. coli* are frozen in milk, pure and diluted to various degrees with water, the death rate of *B. coli* increases with the dilution, the largest numbers surviving in the un-

diluted milk and the fewest in that containing the most water.

IV. When suspended in aqueous mixtures containing from 5 per cent. to 42 per cent. of chemically pure glycerin and held at  $-20^{\circ}\text{C}$ ., a very large percentage of *B. coli* remain alive for at least six months.

V. At  $+37^{\circ}\text{C}$ ., *B. coli* in water or in 5 per cent. to 20 per cent. glycerin<sup>2</sup> die rapidly, few if any remaining alive at the end of 72 hours. The death rate diminishes as the holding temperature is lowered, though it is still marked even just above  $0^{\circ}\text{C}$ .; but at a temperature slightly lower a sudden change appears, the death rate at and below that point being but little, if any, greater than at  $-20^{\circ}\text{C}$ .

VI. By covering a 24-hour growth on agar with a sterile 10 per cent. cane sugar solution, and holding at  $-10^{\circ}\text{C}$ ., stock cultures of *B. subtilis*, *B. aurococcus*, *B. megaterium*, *B. fluorescens*, *B. proteus* and *Sarcina aurantia-cus* have been kept in a vigorous condition (without transferring) for eight months.

From these results the following conclusions may be drawn:

Low temperatures alone do not destroy bacteria. On the contrary, they appear to favor bacterial longevity doubtless by diminishing destructive metabolism. Frozen food materials, such as ice cream, milk and egg substance, favor the existence of bacteria at low temperatures, not because they are foods, but apparently because they furnish physical conditions somehow protective of the bacteria.

It seems likely that water-bearing food materials as well as sugar solutions, glycerin solutions, etc., freeze in such a way that most of the bacteria present are extruded from the water crystals with other non-aqueous matters (including air) and lie in or among these matters without being crushed or otherwise injured; while in more purely watery suspen-

<sup>2</sup> Glycerine mixtures much exceeding 20 per cent., at temperatures above the freezing point of water, act as mild antiseptics. Under 20 per cent. this is not the case, the death of the bacteria apparently resulting from lack of food, as it does not occur when a small amount of peptone is present.

sions, and, above all, in water itself in which the whole mass becomes solidly crystalline, they have no similar refuge but are perhaps caught and ultimately mechanically destroyed between the growing crystals. This theory would explain the absence of live bacteria in clear ice, their comparative abundance in "snow" ice and "bubbly" ice, and also the fact that the more watery food materials when frozen contain the fewest, and the least watery the most, living bacteria.

The comparatively rapid death of bacteria in non-nutrient materials at higher temperatures and their slower dying at lower temperatures agrees well with the theory of simple starvation or destructive metabolism. At the higher temperatures they perish quickly because they burn themselves out quickly; at the lower, more slowly, because they consume themselves more slowly. At temperatures where metabolism ceases altogether they continue to exist in a state of suspended vitality similar to that exhibited by many other and higher plants which in the far north are subjected without apparent injury for long periods to temperatures much below the freezing point of water.

S. C. KEITH, JR.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY.

#### HEMOPHORIC FUNCTION OF THE THORACIC DUCT IN THE CHICK

IN a recent investigation of the development of the thoracic duct in the common fowl, the writer studied also certain aggregations of mesodermal cells correlated with the developing duct, and considered by Sala,<sup>1</sup> more than ten years ago, as "cords" of mesenchymal cells out of which were "hollowed" the rudiments of the duct.

The writer believes, and in the near future will publish evidence to substantiate the belief, that these aggregations of mesodermal (mesenchymal) cells comprise developing blood cells which are differentiated *in situ* out of the indifferent mesenchymal syncytium, that these blood cells then gain access to the lymph

<sup>1</sup> Sala, *Ricerche fatta nel Lab. di Anat. Norm. della R. Univ. di Roma*, Vol. 7, 1900.

channels making up the developing thoracic duct, and that finally the hemal cellular elements in question reach the blood stream *via* the thoracic duct and jugular lymph sac. Considering the vast number of blood cells, especially erythrocytes, arising in this region and the probability that they are conveyed to the general circulation by the thoracic duct, this duct assumes, therefore, an additional phase of importance in the chick in that it performs a hemophoric, or blood-carrying, function.

The view that the thoracic duct may arise as detached portions of veins is in the case of the chick quite untenable, since the tissue in which the lymph spaces and channels arise remains notably non-vascular up to the time the first lymphatics appear. The writer believes he has sufficient evidence, soon to be published, to show that the lymphatics arise as isolated lacunae directly from mesenchymal intercellular spaces, are not in any sense derived from veins, and subsequently coalesce to form the continuous channels of the thoracic duct.

The point recently made by other investigators,<sup>2</sup> namely, that the superficial lymph plexus in the region of the posterior lymph heart in the chick contains stagnant blood which has backed up into it from the veins, is invalid in the case of the thoracic and its blood content because there are no veins in this region from which "backing up" could occur.

ADAM M. MILLER

#### A POSSIBLE MEANS OF IDENTIFYING THE SEX OF (+) AND (—) RACES IN THE MUCORS

It has been shown by the writer (1) that the majority of the forms among the mucors are dioecious, with the sexes separated in male and female races which are capable of being propagated apparently to an indefinite number of vegetative generations by means of nonsexual spores formed in sporangia. In all the dioecious species carefully investigated the opposite gametes, which are produced and unite to form zygospores when the two sexual

racess of a given form are grown together, do not appear to differ morphologically. Lacking a definite criterion which an inequality of the gametes would have afforded, the writer has provisionally designated the opposite sexes in these forms by the signs (+) and (—) on account of a generally greater vegetative luxuriance of one sex over the other. That in reality the two sexes are represented in the (+) and (—) groups is shown by the sexual reaction which may occur not only when the (+) and (—) races of the same species are grown together and perfect zygospores are produced, but also by the sexual reaction which may occur when (+) and (—) races belonging to different species are grown together. This reaction between the opposite races of different species has been called imperfect hybridization since it does not lead to the formation of perfect hybrid zygospores, but usually stops short with the formation of progametes, though occasionally gametes are produced which, however, never unite.

A sexual race of a dioecious species if grown between the (+) and (—) races of another test species used as a standard, will show a line of sexual reactions on one side only. Some of the hermaphroditic species, on the other hand, when similarly grown, show a response to both (+) and (—) test races and produce therefore 2 lines of sexual reactions.

Some few species in the hermaphroditic group are distinctly heterogamic with a constant difference in size between the conjugating gametes. Figs. 1-6 in the accompanying diagram will illustrate the process of conjugation in such forms. It seems reasonable to consider the larger gamete female and the smaller male. Upon this basis, if a sexual reaction could be established between these unequal gametes and the (+) and (—) races, the race reacting with the larger female gamete must be considered male, while the race reacting with the smaller male gamete must be considered female.

<sup>1</sup> "Zygospore Formation a Sexual Process," SCIENCE, N. S., 19: 864-866, 1904; "Sexual Reproduction in the Mucorinæ," *Proc. Am. Acad.*, 40: 205-319, pls. 1-4, 1904.

<sup>2</sup> Clark, E. L., *Anat. Record*, Vol. 6, No. 6, 1912; Clark, E. R., *Anat. Record*, Vol. 6, No. 6, 1912.

The difficulties in technique involved in following the sexual reactions in a thicket of filaments have been overcome by growing the heterogamic hermaphrodite ( $\delta$ ) in a Petri dish between the (+) and (—) test strains and cutting channels in the nutrient agar between the different growths. If the Petri dish be then inverted, the growth of the reacting filaments may be followed in mid air in the channels.

Only a single heterogamic species has been found which will give reactions with both (+) and (—) races and only a single dioecious

the smaller  $\delta$  gamete of the hermaphrodite. The male gamete, which has been cut off from a filament of the hermaphrodite at the stimulus of contact with a (+) hypha, frequently surrounds itself with a thick wall and assumes the appearance of a resting azygospore, as is shown at *C*.

Of three other heterogamic hermaphrodites investigated, two show a sexual reaction with the (+) race only and one with the (—) race only. It is difficult to interpret the sexual reaction when shown with only one of the two sexual races.

SEXUAL REACTION BETWEEN A HERMAPHRODITIC MUCOR AND (+) AND (—) RACES  
OF A DIOECIOUS SPECIES

Diagrammatic representation of a Petri dish culture showing a heterogamic hermaphroditic mucor ( $\delta$ ) in the center separated by channels on either side from the (+) and (—) races, respectively, of a dioecious species.

Sp., Sporangia containing spores by means of which the plant may be reproduced nonsexually.

1-6, stages in development of a hermaphroditic zygospore from unequal  $\delta$  and  $\delta$  gametes.

A, sexual reaction between a (—) filament and ♀ gamete.

B, sexual reaction between a (+) filament and ♂ gamete.

C, a  $\delta$  azygospore formed at stimulus of contact with a (+) filament.

species which will react with both male and female gametes of this heterogamic hermaphrodite. These have accordingly been used in making the tests shown in the accompanying diagram.

In the left hand channel at *A* in the diagram, a filament from the (—) race is shown giving a sexual reaction with the larger ♀ gamete of the hermaphrodite, while in the right hand channel at *B* a filament of the (+) race is figured, showing a sexual reaction with

Judging from the behavior of the forms figured in the diagram one would seem justified in considering the vegetatively more vigorous (+) race as female and the less vigorous (—) race as male.

The details upon which the conclusions in the present article are based are being published in another journal. The article itself is a summary of a paper presented before the Botanical Society of America, January 2, 1913.

A. F. BLAKESLEE

THE EFFECT OF MOLTING ON RHEOTAXIS IN  
ISOPODS

In an earlier paper<sup>1</sup> I showed that the strength of a current in which stream isopods can maintain themselves is determined by the period of weakened responses during the breeding season. More recent studies have shown that the shorter but more frequently recurring molting period is also of importance in this respect.

The molt in the isopod, *Asellus communis* Say, usually occurs at intervals of from 13 to 25 days, although over 70 days may elapse between molts. Normally the covering breaks between the fourth and fifth thoracic segments. Either the anterior or posterior part may be shed first. Both may be molted the same night or as long as four days may intervene between the molting of the two halves. At times parts or all of the covering may be molted, segment by segment, or even parts of a segment may break off; as long as nine days has been observed to be spent in molting the abdomen alone.

The influence of this period on the rheotactic reaction is typically shown by the following account of the responses of an isopod during one molting period. The isopod under observation was a male, 12 mm. long, which averaged normally 86 per cent. positive rheotactic reactions. The molt began just after a test of 11 trials which averaged 35 per cent. positive, 35 per cent. negative and 30 per cent. indefinite. During each minute's reaction the isopod moved an average distance of 40 centimeters.

The covering broke between the fourth and fifth thoracic segments and the forward part was worked off over the head by a series of undulating motions of the body and by movements of all the legs. It took 70 seconds to complete the process. One of the antennæ that had been dragging before the molt occurred was dropped off with the exuvia. Im-

mediately after the molt the forelegs were smaller than usual.

During the process the isopod stayed in one place and disregarded all currents. A current set up immediately after the molt was completed was also disregarded. After about two minutes in the same place the isopod moved across the pan and stopped in an angle 17 cm. away. It rested there quietly for seventeen minutes, when it was again tested for rheotactic reaction. No movement occurred. At thirty minutes after molting 10 trials showed 30 per cent. positive, 60 per cent. indefinite and 10 per cent. no reaction at all. The average reaction distance per minute was 35 cm.

At this time the isopod was more sensitive to touch stimuli than usual. In the response just given it twice ran into another isopod with its antennæ and jumped back over a centimeter each time, although normally there would have been almost no negative reaction.

Three hours after molting, 70 per cent. of the reactions were positive, and two hours later 90 per cent. were positive and the reaction distance was 47 cm. This last trial was characterized by the steady movements and rapid, definite orienting that mark the normal response of stream isopods.

In this case the molt of the posterior part occurred two days later, after nine p.m. At nine the response was: 40 per cent. positive, 40 per cent. negative and 20 per cent. indefinite. The next morning 80 per cent. of the responses were positive and the other 20 per cent. were negative. The reaction distance was only slightly greater in the morning readings. On the morning after the next molt 31 days later, this isopod would start positive and turn negative as though the current pressure against the more sensitive covering was painful.

An isopod stands higher from the bottom when nearing molting time, which is probably due to the increasing stiffness of its legs. At this time the posterior legs appear harder to move and may become tangled, thus throwing the isopod as it tries to crawl. Immediately after the molt it is more easily swept off its

<sup>1</sup> Allee, W. C., 1912, "An Experimental Analysis of the Relation between Physiological States and Rheotaxis in Isopoda," *Jour. Exp. Zool.*, Vol. 13, pp. 269-344.

feet than during other parts of the molting cycle.

The more gradual molts may also affect the rheotactic reaction. A cut of 20 per cent. in the positive response has been observed when one segment was molted. Regulation from depressed to normal positiveness occurs more rapidly after a molt than at any other time.

The detailed account just given shows that the effect of the molting period lasted for about five hours after the actual ecdysis took place. If the period extended as long beforehand it would make the time during which the rheotactic response is affected by the molting process extend over a period of ten hours. Since both the rheotactic and thigmotactic responses are weakened, this must be a critical time in the life of the stream isopod.

W. C. ALLEE

A NEVADA RECORD FOR THE CANADA OTTER,  
*LUTRA CANADENSIS* (SCHREBER)

No otter has apparently been known from Nevada, although *Lutra canadensis* is known to occur in Idaho, and the type specimen of *L. canadensis sonora* (Rhoads) was taken at Montezuma Well, Yavapai County, Arizona. The Walker-Newcomb Expedition of the University of Michigan, in the summer of 1912, found a species common on the Humboldt River in the vicinity of Elko and Carlin, in the northeastern part of the state, and from a trapper a specimen was secured for the Museum of Zoology (Cat. No. 44,419).

The specimen obtained, a large adult male, is evidently to be referred to *L. canadensis*, as at present defined. The coloration is not as pale as described for *L. c. sonora*, being dark liver-brown above and paler below, the cheeks, lips, chin and throat whitish; and the post-orbital processes are not attenuated, as in *L. c. sonora*, but short and stout, as in typical *L. canadensis*.

ALEXANDER G. RUTHVEN,  
FREDERICK M. GAIGE

SOCIETIES AND ACADEMIES

THE BOTANICAL SOCIETY OF WASHINGTON

THE eighty-seventh regular meeting of the Botanical Society of Washington was held at the Hotel Cochran, February 25, 1913. This was the

regular annual opening meeting of the society. Fifty members and forty-two guests were present.

The retiring president, Mr. W. A. Orton, delivered an address entitled "Environmental Influences in the Pathology of *Solanum tuberosum*." This paper was published in the *Journal of the Washington Academy of Sciences* (Vol. 3, p. 180, April 4, 1913).

The eighty-eighth regular meeting was held in Assembly Hall, Cosmos Club, Tuesday evening, April 1, 1913.

Mr. James T. Jardine was elected to membership.

The following papers were presented:

*Notes on Diseases of Trees caused by Mistletoes:*

Dr. G. G. HEDGCOCK.

Mistletoes are found only on conifers in northern and northeastern United States; only on angiosperms in southeastern and southern portions; and on both in western and southwestern regions, where they are the most widely disseminated.

The rate of spread of mistletoes is without doubt very slow. Near Frazer, Colorado, on an old burn in the forest, the rate of spread of *Razoumofskyia americana* (Nutt.) Kuntze on the lodge pole pines (*Pinus contorta* Lond.) is estimated to be from 6 to 12 feet per annum, where mechanical expulsion of the seeds aided by winds are the controlling factors. Sporadic infections at much greater distances are caused possibly by birds or animals.

Light is the most important factor in determining the spread of mistletoes of species of both *Razoumofskyia* and *Phoradendron*. Trees in the open, and in more exposed conditions, whether on ridges or edges of canyons or on level areas are most subject to attacks by mistletoes of both genera on account of the abundance of light. Trees in dense forests are not subject to attack. Mistletoes are stunted by dense shade, and bear but few, if any seeds, and can not well maintain themselves under conditions where the light is deficient.

One of the immediate effects of the presence of the sinkers of these parasites in the tissues of host trees and shrubs is a tendency to hypertrophy in the immediate region of penetration. In case of species of *Phoradendron*, unless the mistletoe plant is broken off there is little or no tendency for its sinkers to spread laterally in the tissues of the host, and when broken off, the rate of spread is slow, and no witches brooms are formed. In case of species of *Razoumofskyia*, witches brooms are commonly produced. The lateral sinkers in such cases spread in the soft tissues of the host, keeping

pace with each year's growth, and sending forth new aerial shoots, from time to time. The stimulus of the presence of this ramifying network of the sinkers of the parasite causes an increase in the number of buds and twigs produced by the limb of the host attached and results in the formation of a more or less dense witches broom. The ability of the mistletoe to grow out to the extremities of the limbs enables it to send out shoots in the best illuminated portion of the broom, and bear seeds under the most favorable conditions of light.

All species of mistletoe are considered injurious in their final effect upon their host trees and shrubs. The leafy *Phoradendrons* are no doubt less injurious, owing to their increased chlorophyll-bearing surface and consequent greater ability to manufacture hydrocarbons. The leafless species of *Phoradendron* are more injurious than leafy ones. Species of *Razoumofskya*, owing to a very greatly reduced chlorophyll-bearing surface, are the most injurious of all. All species stunt the growth of the hosts. Owing to the slow spread of species of mistletoe in the forest, if all diseased trees are cut down on areas where timber sales are conducted, it will be possible to greatly lessen, if not entirely shut out these parasites from our future forests.

*Notes on the Botany of Trinidad:* Professor A. S. HITCHCOCK.

Mr. Hitchcock remained on the island of Trinidad from November 25 until December 31, except a few days spent on Tobago. On Trinidad there were collected 350 numbers of grasses, representing about 175 species. Grisebach (Fl. Brit. W. Ind.) describes 87 species from the island and Hart (Herb. List, Bot. Dept. Trinidad) lists 112 species. Several species known to grow in Trinidad were not obtained by Mr. Hitchcock, but many species were added to the known flora. Among the more interesting regions of the island were the Pitch Lake, where several species of grasses were found that were observed nowhere else, including *Panicum chloroticum* growing only in the water-holding depressions of the pitch; Aripo and Piarcó Savannas, isolated low flat grassy openings in the valley of the Caroni River, where were found a probably new species of *Raddia* and *Paspalum serpentinum* Hochst. not found since the original collection by Keppeler in Surinam nearly a century ago, and two new species of *Panicum*; and St. Joseph Savanna on the mountain side near the ancient capital of the island, St. Joseph. This savanna is of especial interest

because the mountain sides are generally covered with forest except where cleared for cultivation. This savanna has occupied its present position since an indefinitely early period, as shown by the flora. The dominant grass is *Trachypogon plumosus*, a species which has not been reported from Trinidad. This species together with others of the association are the common constituents of the savannas found on the Pacific slope of Panama and Central America. In this savanna was found an undescribed species of *Axonopus*, a beautiful golden annual, allied to *A. aureus*. At Tabaguite in the center of the island in the original forest or "High woods" was found another undescribed species of *Raddia* and the rare *Pharus parvifolius* Nash. Several other apparently undescribed species were found on various parts of the island. Most of the species, whose types were from Trinidad, were recollected at their type localities. The results of the expedition to Trinidad and to Jamaica, visited earlier on the same trip, were very satisfactory and will supplement the large West Indian collections previously incorporated in the National Herbarium.

C. L. SHEAR,

*Corresponding Secretary*

THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

THE 468th regular and 34th annual meeting of the Anthropological Society of Washington was held in room 43 of the new building of the National Museum at 4:30 P.M., April 15, 1913, the president, Mr. Stetson, in the chair.

The minutes of the last preceding annual meeting were read and approved.

Obituary notices were presented as follows: Miss Alice Fletcher for Miss Sarah A. Scull; Mr. F. W. Dodge for Mr. W. J. McGee; Dr. Lamb for Dr. Robert Fletcher.

The following officers were elected and installed for the ensuing year:

*President*—Mr. George R. Stetson.

*Vice-president*—Dr. John R. Swanton.

*Secretary*—Dr. Daniel Folkmar.

*Treasurer*—Mr. J. N. B. Hewitt.

*Councillors*—Mr. George C. Maynard, Mr. Felix Neumann, Dr. I. M. Casanowicz, Dr. E. L. Morgan and Mr. Francis LaFlesche.

Invitations to meetings of the National Academy of Sciences and the German Anthropological Association were presented and accepted with thanks.

WM. H. BABCOCK,

*Secretary*

# SCIENCE

NEW SERIES  
VOL. XXXVII. No. 963

FRIDAY, JUNE 13, 1913

SINGLE COPIES, 15 Cts.  
ANNUAL SUBSCRIPTION, \$5.00

## LIQUID AIR OXYGEN AND NITROGEN

By GEORGES CLAUDE, Engineer Laureat of the Institute of France. Translated by H. E. P. COTTRELL, Assoc. M.I.C.E. With 151 Illustrations. Octavo. Cloth. \$5.50 postpaid.

This book discusses the subject from a thoroughly practical point of view, giving the points that are of benefit in Lighting, Metallurgy, Chemistry, Sanitation, Agriculture, etc. It is a new book possessing entirely original characteristics and thoroughly illustrated.

## THE PRINCIPLES OF BIOLOGY

INCLUDING BRIEF OUTLINES FOR  
LABORATORY WORK

By J. I. HAMAKER, Professor of Biology, Randolph-Macon Woman's College, College Park, Virginia. 267 Illustrations. 12mo. 469 pages. Cloth, \$1.50 postpaid.

This book is divided into three parts. Part I gives the fundamentals of plant organization and life processes. Part II does the same for Animals. Part III discusses the more important general biological phenomena.

## THE PLANT ALKALOIDS

By THOMAS A. HENRY, D.Sc., F.C.S., Superintendent of Laboratories, Imperial Institute, England. Octavo. 473 pages. Cloth. \$5.00 postpaid.

Many of the Alkaloids are of great importance in medicine, and the manufacture of these alkaloids and products containing them constitutes important branches of the "fine chemical" industry. In this volume the author describes not only the properties and chemistry of the products but also their occurrence, methods of estimation, and physiological action, etc.

## GERMAN-ENGLISH MEDICAL DICTIONARY

2nd Edition

By the late Dr. HUGO LANG, B.A. (Munich). Second Edition, Edited and Revised by MILTON K. MEYERS, M.D., Neurologist to the Jewish Hospital Dispensary, and to St. Agnes Hospital Dispensary, Philadelphia, etc. Octavo. 571 pages. Cloth. \$5.00 postpaid.

This new edition contains 4,400 definitions in addition to the more than 45,000 published in the last edition. These latter have been carefully revised and corrected and the book as it now stands should prove an indispensable aid in the translation of German medical literature.

## PHYSICS AND CHEMISTRY OF COLLOIDS

By EMIL HATSCHEK. London. With illustrations. 12mo. Cloth. \$1.00 postpaid.

This book is intended as an introduction to the subject and gives the fundamental facts and methods of this important branch of chemistry. The subject is divided into ten chapters and contains, besides the general index, an index of names.

## EXAMINATION OF WATERS AND WATER SUPPLIES (2nd Ed.)

By JOHN C. THRESH, M.D. (Vic.), D.Sc. (Lond.), Medical Officer of Health, Essex County Council; Lecturer of Public Health, London Hospital Medical College. 2nd edition. With 36 plates and 17 text figures. Octavo. 664 pages. Cloth. \$5.00 postpaid.

This edition has been enlarged by 186 pages and contains 17 more plates and 6 more text figures than the first.

## Precision Optical Instruments

MADE BY ADAM HILGER, Ltd.

Hilger Quartz Spectrograph, Size C

The firm of Adam Hilger, Ltd. manufactures a large and comprehensive line of precision optical instruments. For the perfection of the optical and mechanical construction of their instruments this firm is well known all over the world. The following is a suggestive list of the instruments manufactured:—

Wavelength Spectrometers, Monochromatic Illuminators, Violet Glass and Quartz Spectrographs, Fery Spectrograph, Houston Polarization Photometer Attachment, Nutting Polarization Photometer Attachment, Pocket and other direct vision Spectroscopes, Micrometers, Polarimeters and Refractometers, Fery Refractometers, Interferometers, Spectroscopic Apparatus for High Resolving Power, Solar and Stellar Spectroscopes, Spectrometers, and Goniometers for general work, Accessories of all kinds for use with instruments.

As special representatives of Adam Hilger, Ltd., in this country we are prepared to furnish latest catalog matter and also further details and quote best prices for special duty-free importation.

When in Philadelphia be sure to visit our Permanent Exhibit of scientific apparatus.

The "Greenough Leitz" Binocular Travelling Microscope in Case.

### "GREENOUGH LEITZ" Stereoscopic Image Erect- ing Microscopes

Embodying a new type of construction, providing greater stability than in all previously existing models.

Rigid adjustments of microscope tubes with Porco Prisms is assured by the placing of rack and pinion independent of such adjustments.

Patented Elastic Prism Mounting in Steel Springs—same as in our Prism Binocular Field Glasses.

Upper part of microscope with prism tubes is removable, for attachment to a special hard rubber foot (with independent rack and pinion coarse adjustment), serving conveniently in examination of large surfaces (Dermatoscope Arrangement).

Paired objectives mounted on self centering slides, and can be adjusted relatively to each other. One objective in focusing mount to overcome difference of refraction between the observer's eye.

The "Greenough Leitz" is also made in Folding Form, meeting a long felt demand of those who require this instrument when in the field. Supplied in a convenient sized morocco case.

## CONCERNING THE FIGURE AND THE DIMENSIONS OF THE UNIVERSE OF SPACE<sup>1</sup>

THERE is something a little incongruous in attempting to consider the subject of this address in a theater or lecture hall whose roof and walls shut out from view the wide expanses of the world and the azure deeps. For how can we, amid the familiar finite scenes of a closed and blinded room, command a fitting mood for contemplating the infinite scenes without and beyond? A subject that has sheer vastness for its central or major theme demands for its appropriate contemplation the still expanse of some vast and open solitude, such as the peak of a lone and lofty mountain would afford, where the gaze meets no wall save the far horizon and no roof but the starry sky. Perhaps you will be good enough for the time to transport yourselves, in imagination, into the stillness of such a solitude, so that in the musing spirit of the place the questions to be propounded for consideration here may arise naturally and give us a due sense of their significance and impressiveness. What are the dimensions and what is the figure of our universe of space? How big is it and what is its shape? What is the figure of it and what is its size?

I do not mind owning that these questions have haunted me a good deal from the days of my youth. It happened in

<sup>1</sup> An address delivered under the auspices of the local chapters of the Society of Sigma Xi at the state universities of Minnesota, Nebraska and Iowa, April 24, 28 and 30, respectively, and at a joint meeting of the chapters of Sigma Xi and Phi Beta Kappa of Columbia University, May 8.

those days, though I was not aware of it nor became aware of it till after many years, that there were then coming into mathematics, just entering the fringe, so to speak, or the vestibule of the science, certain striking ideas which, as I venture to hope we may see, were destined, if not indeed to enable us to answer the questions with certainty, at all events to clarify them, to enrich their meaning and to make it possible to discuss them profitably. It has not been my fortune to meet many persons who had seriously propounded the questions to themselves or who seemed to be immediately interested in them when propounded by others—not many, even among astronomers, whose minds, it may be assumed, are specially “accustomed to contemplation of the vast.” And so I have been forced to the somewhat embarrassing conclusion that my own long interest in the questions has been due to the fact of my being of a specially practical turn of mind. Quite seriously I venture to say that we are here engaged in a practical enterprise. For even if the questions were in the nature of the case unanswerable, which we do not admit, who does not know how great the boons that have come to men through pursuit of the unattainable? And who does not know that, as Mr. Chesterton has said, if you wish really to know a man, the most practical question to ask is, not about his occupation or his club membership or his party or church affiliations, but what are his views of the all-embracing world? What does he think of the universe? Do but fancy for a moment that in somewise men should come to *know* the exact shape or figure and especially the exact size or dimensions of the all-immersing space of our universe. It requires but little imagination, not much reflection, no extensive knowledge of cosmogonic history and spec-

ulation, no very profound insight into the ways of truth to men; it needs, I say, but little philosophic sense to see that such knowledge would in a thousand ways, direct and indirect, react powerfully upon our whole intelligence, upon all our attitudes, sentiments and views, transforming our theology, our ethics, our art, our religion, our philosophy, our literature, our science, and therewith affect profoundly the whole sense and manner, the tone, color and meaning, of all our institutions and the affairs of daily life. Nothing is quite so practical, in the sense of being effectual and influential, as the views men hold, consciously or unconsciously, regarding the great locus of their lives and their cosmic home.

In order to discuss the questions before us intelligibly and profitably it is not necessary by way of clearing the ground to enter far into metaphysical speculation or into psychological analysis with a view to ascertaining what it is that we mean or ought to mean by space. We are not obliged to dispute, much less decide, whether space is subjective or objective or both or indeed something that, as Plato in the “*Timæus*” acutely contends, is neither the one nor the other. We may or may not agree with the contention of Kant that space is, not an object, but the form, of outer sense; we may or may not agree with the radically different contention of Poincaré that (geometric as distinguished from sensible) space is nothing but what is known in mathematics as a group, of which the concept “is imposed on us, not as form of our sense, but as form of our understanding.” It is, I say, not necessary for us, in the interest of soundness and intelligibility, to try to compose such differences or to attempt a settlement of these profound and important questions. As to the distinction between

sensible space and geometric space, it would indeed be indispensable to draw it sharply and to keep it always in mind, if we were undertaking to ascertain what the subject (or the object) of geometry is, or, what is tantamount, if we were seeking to get clearly aware of what it is that geometry is about. But in discussing the subject before us it is unnecessary to be always guarding that distinction; for, whilst it is the space of geometry, and not sensible space, that we shall be talking about, yet it would be a hindrance rather than a help if we did not allow, as we habitually do allow, the two varieties of space—the imagery of the one, the conceptual characters of the other—to mingle freely in our thinking. There will be finesse enough for the keenest arrows of our thought without our going out of the way to find it. A procedure less sophisticated will suffice. It will be sufficient to regard space as being what, to the layman and to the student of natural science, it has always seemed to be: a vast region or room round about us, an immense exteriority, locus of all suspended and floating objects of outer sense, the whence, where and whither of motion, theater, in a word, of the ageless drama of the physical universe. In naturally so construing the term we do not commit ourselves to the philosophy, so-called, of common sense; we thus merely save our discourse from the encumbrance of needless refinements; for it is obvious that, if space be not indeed what we have said it seems to be, the seeming is yet a fact, and our questions would remain without essential change: what, then, we should ask, are the dimensions and what is the figure of that seeming?

Though all the things contained within that triply extended spread or expanse which we call space are subject to the law

of ceaseless change, the expanse itself, the container of all, appears to suffer no variation whatever, but to be, unlike time, a genuine constant, the same yesterday, to-day and forever, sole absolute invariant under the infinite host of transformations that constitute the cosmic flux. Whether it be so in fact, of course we do not know. We only know that no good reason has ever been advanced for holding the contrary as an hypothesis.

And yet there is a sense, which we ought I think to notice, an interesting sense, in which space seems to be, not a constant, but, like time, a variable. There is a sense, deeper and juster perhaps than at first we suspect, in which the space of our universe has in the course of time alternately shrunken and grown. During the last century, for example, it has, so it seems, greatly grown, in response, it may be, to an increasing need of the human mind. By grown I do not mean grown in the usual sense, I do not mean the biological sense, I do not mean the sense that was present to the mind of that great man, Leonardo da Vinci, when he wrote in effect as follows: if you wish to know that the earth has been growing, you have only to observe "how, among the high mountains, the walls of ancient and ruined cities are being covered over and concealed by the earth's increase"; and, if you would learn how *fast* the earth is growing, you have only to set a vase, filled with pure earth, upon a roof; to note how green herbs will immediately begin to shoot up; to note that these, when mature, will cast their seeds; to allow the process to continue through repetition; then, after the lapse of a decade, to measure the soil's increase; and, finally, to multiply, in order to have thus determined "how much the earth has grown in the course of a thousand years." In this matter, Leo-

nardo was doubtless wrong. At all events current scientific views are against him. The earth, we know, has grown, but the growth has been by accretion, by addition from without, and not, in biologic sense, by expansion from within (unless, indeed, we adopt the beautiful hypothesis of the poet and physicist, Theodor Fechner, for which so hard-headed a scientific man as Bernhard Riemann had so much respect, the hypothesis, namely, that the plants, the earth and the stars have souls). The myriad-minded Florentine was, we of today think, in error, his error being one of those brilliant mistakes that but few men have been qualified to make. But in saying that space has grown we do not mean that it has grown in the biologic sense of Leonardo nor yet in the sense of addition from without. We mean that it has grown as a thing in mind may grow, as a thing in thought may grow; we mean that it has grown in men's conception of it. That space has, in this sense, been enlarged prodigiously in the course of recent time is evident to all. It has been often said that the first grand discovery of modern times is the immense extension of the universe *in space*." It would be juster to say that the first grand achievement of modern science has been the immense extension of space itself, the prodigious enlargement of it, in the imagination and especially in the thought of men. If we will but take the trouble to recall vividly the Mosaic cosmogony, in terms of which most of us have but recently ceased to frame our sublimest conceptions of the vast; if we remind ourselves of Plato's "concentric crystal spheres, the adamant axis turning in the lap of necessity, the bands that held the heaven together like a girth that clasps a ship, the shaft which led from earth to sky, and which was paced by the soul in a

thousand years"; if we compare these conceptions with our own; if we think of "the fields from which our stars fling us their light," fields that are really near and yet are so far that the swiftest of messengers, capable of circling the earth eight times in a second, requires for its journey hither thousands of years; if we do but make some such comparisons, we shall begin to realize dimly that, compared with modern space—the space of modern thought—elder space—the space of elder thought—is indeed "but as a cabinet of brilliants, or rather a little jewelled cup found in the ocean or the wilderness."

Suppose that in fact space were thus, like time, not a constant, but a variable; suppose it were a mental thing growing with the growth of mind; an increasing function of increasing thought; suppose it were a thing whose enlargement is essential as a psychic condition or concomitant or effect of the progress of science; would not our questions regarding its figure and its dimensions then lose their meaning? The answer is, no; as rational beings we should still be bound to ask: what are the dimensions and what is the figure of space to date? That is not all. If these questions were answered, we could propound the further questions: whether the space so characterized—the space of the present—is adequate to the present needs of science, and whether it is not destined to yet further expansion in response to the future needs of thought.

Men do not feel, however, that such spatial enlargements as I have indicated are genuine enlargements of space. In spite of whatever metaphysics or psychology may seem obliged to say to the contrary, men feel that what is *new* in such an enlargement is merely an increase of enlightenment regarding something old; they

feel that what is new is, not an added vastness, but a discovery of a vastness that always was and always will be. Let us trust this feeling and, regarding space as constant from everlasting to everlasting, let us take the questions in their natural intent and form: what are the dimensions and what is the figure of our universe of space?

If you propound these questions to a normal student of natural science, say to a normal astronomer, his response will be—what? If you appear to him to be quite sincere and if, besides, he be in an amiable mood, his response will, not improbably, be a significant shrug of the shoulders, designed to intimate that his time is too precious to be squandered in considering questions that, if not meaningless, are at all events unanswerable. I maintain, on the contrary, that this same student of natural science and, indeed, all other normally educated men and women, have, as a part of their intellectual stock in trade, perfectly definite answers to both of the questions. I do not mean that they are aware of possessing such wealth nor shall I undertake to say in advance whether their answers be correct. What I am asserting and what, with your assistance, I shall endeavor to demonstrate, is that perfectly precise, very intelligent and perfectly intelligible answers to both of the questions are logically involved in what every normally educated mind regards as the securest of its intellectual possessions. In order to show that such answers are to be found embedded in the content of the normally educated mind and in order to lay them bare, it will be necessary to have recourse to the process of explication. Explication, however, is nothing strange to an academic audience. It is true, indeed, that we no longer derive the verb, to educate, from *educere*, but it is yet a fact, as every one knows, that a large part of education is *eduction*—the leading

forth into light what is hidden in the familiar content of our minds.

What are those answers? I shall present them in the familiar and brilliant words of one who in the span of a short life achieved a seven-fold immortality: immortality as a physicist, as a philosopher, as a mathematician, as a theologian, as a writer of prose, as an inventor and as a fanatic. From this brief but “immortal” characterization I have no doubt that you detect the author at once and at once recall the words: *Space is an infinite sphere whose center is everywhere and whose surface is nowhere.*

You will observe that, without change of meaning, I have substituted “space” for “universe” and “surface” for “circumference.” This brilliant *mot* of Blaise Pascal, as every one knows, has long been valued throughout the world as a splendid literary gem. I am not aware that it has been at any time regarded seriously as a scientific thesis. It may, however, be so regarded. I propose to show, with your cooperation, that this exquisite saying of Pascal expresses with mathematical precision the firm, albeit unconscious, conviction of the normally educated mind respecting the size and the shape of the space of our universe. Be good enough to note carefully at the outset the cardinal phrases: *infinite sphere, center everywhere, surface nowhere.*

If you are told that there is an object completely enclosed and that the object is equally distant from all parts of the enclosing boundary or wall, you instantly and rightly think of a sphere having that object as center. Let me ask you to think of some point, any convenient point, *P*, together with all the straight lines or rays—called a sheaf of lines or rays—that, beginning at *P*, run out from it as far as ever the nature of space allows. We ask: do all the rays of the sheaf run out equally far? It seems

perfectly evident that they do, and with this we might be content. It will be worth while, however, to examine the matter a little more attentively. Denote by  $L$  any chosen line or ray of the sheaf. Choose any convenient unit of length, say a mile. We now ask: how many of our units, how many miles can we, starting from  $P$ , lay off along  $L$ ? Lay off, I mean, not in fact, but in thought. In other words: how many steps, each a mile long, can we, in traversing  $L$ , take in thought? Hereafter let the phrase "in thought" be understood. Can the question be answered? It can. Can it be answered definitely? Absolutely so. How? As follows. Before proceeding, however, let me beg of you not to hesitate or shy if certain familiar ideas seem to get submitted to the logical process—the mind-expanding process—of generalization. There is to be no resort to any kind oflegerdemain. Let us be willing to transcend imagination, and, without faltering, to follow thought, for thought, free as the spirit of creation, owns no bar save that of inconsistency or self-contradiction. Consider the sequence of cardinal numbers,

$$(S) \quad 1, 2, 3, 4, 5, 6, 7, \dots$$

The sequence is neither so dry nor so harmless as it seems. It has a beginning; but it has no end, for, by the law of its formation, after each term there is a next. The difference between a sequence that stops somewhere and one that has no end is awful. No one, unless spiritually unborn or dead, can contemplate that gulf without emotions that take hold of the infinite and everlasting. Let us compare the sequence with the ray  $L$  of our sheaf. Choose in  $(S)$  any number  $n$ , however large. Can we go from  $P$  along  $L$  that number  $n$  of miles? We are certain that we can. Suppose the trip made, a mile post set up and on it painted the number  $n$  to tell how far the post is from  $P$ . As  $n$

is any number in  $(S)$ , we may as well suppose, indeed we have already implicitly supposed, mile posts, duly distributed and marked, to have been set up along  $L$  to match each and every number in the sequence. Have we thus set up all the mile posts that  $L$  allows? We are certain that we have, for, if we go out from  $P$  along  $L$  any possible but definite number of miles, we are perfectly certain that that number is a number in the sequence, and that accordingly the journey did but take us to a post set up before. What is the upshot? It is that  $L$  admits of precisely as many mile posts as there are cardinal numbers, neither more nor less. How long is  $L$ ? The answer is:  $L$  is exactly as many miles long as there are integers or terms in the sequence  $(S)$ . Can we say of any other line or ray  $L'$  of the sheaf what we have said of  $L$ ? We are certain that we can. Indeed we have said it, for  $L$  was *any* line of the sheaf. May we, then, say that any two lines,  $L$  and  $L'$ , of the sheaf are *equal*? We may and we must. For, just as we have established a one-to-one correspondence between the mile posts of  $L$  and the terms of  $(S)$ , so we may establish a one-to-one correspondence between the mile posts of  $L$  and those of  $L'$ , and what we mean by the *equality* of two classes of things is precisely the possibility of thus setting up a one-to-one correlation between them. Accordingly, all the lines or rays of our sheaf are equal. We can not fail to note that thus there is forming in our minds the conception of a sphere, centered at  $P$ , larger, however, than any sphere of slate or wood or marble—a sphere, if it be a sphere, whose radii are the rays of our sheaf. Is not the thing, however, too vast to be a sphere? Obviously yes, if the lines or rays of the sheaf have a length that is indefinite, unassignable; obviously no, if their length be assignable and definite. We have

seen the length of a ray contains exactly as many miles as there are integers or terms in  $(S)$ . The question, then, is: has the totality of these terms a definite assignable number? The answer is, yes. To show it, look sharply at the following fact, a bit difficult to see only because it is so obvious, being writ, so to speak, on the very surface of the eye. I wish, in a word, to make clear what is meant by the cardinal number of any given class of things. The fingers of my right hand constitute a class of objects; the fingers of my left hand, another class. We can set up a one-to-one correspondence between the classes, pairing the objects in the one with those in the other. Any two classes admitting of such a correlation are said to be *equivalent*. Now given any class  $K$ , there is another class  $C$  composed of all the classes each of which is equivalent to  $K$ .  $C$  is called the cardinal number of  $K$ , and the name of  $C$ , if it have received a name, tells how many objects are in  $K$ . Thus, if  $K$  is the class of the fingers of my right hand, the word *five* is the name of the class of classes each equivalent to  $K$ . Now to the application. The terms of  $(S)$  constitute a class  $K$  (of terms). Has it a definite number? Yes. What is it? It is the class of all classes each equivalent to  $K$ . Has this number-class received a name of its own? Yes, and it has, like many other numbers, received a symbol, namely,  $\aleph_0$ , read Aleph null. It is, then, this cardinal number Aleph, not familiar, indeed, but perfectly definite as denoting a definite class, it is this that tells us how many terms are in  $(S)$  and therewith tells us the length of the rays of our sheaf. Herewith the concept that was forming is now completely formed: *space is a sphere centered at  $P$* .

But is the sphere, as Pascal asserts, an *infinite* sphere? We may easily see that it is. Again consider the sequence  $(S)$  and

with it the similar sequence  $(S')$ ,

$$(S) \quad 1, 2, 3, 4, 5, 6, 7, \dots,$$

$$(S') \quad 2, 4, 6, 8, 10, 12, 14, \dots$$

Observe that all the terms in  $(S')$  are in  $(S)$  and that  $(S)$  contains terms that are not in  $(S')$ .  $(S')$  is, then, a proper *part* of  $(S)$ . Next observe that we can pair each term in  $(S)$  with the term below it in  $(S')$ . That is to say: the whole,  $(S)$ , is equivalent to one of its parts,  $(S')$ . A class that thus has a part to which it is equivalent is said to be infinite, and the number of things in such a class is called an infinite number. Aleph is, then, an infinite number, and so we see that the rays of our sheaf, the radii of our sphere, are infinite in length: *space is an infinite sphere entered at  $P$* .

Finally, what of the phrases, *center everywhere, surface nowhere*? Can we give them a meaning consistent with common usage and common sense? We can, as follows. Let  $O$  be any chosen point somewhere in your neighborhood. By saying that the center  $P$  is everywhere we mean that  $P$  may be taken to be *any* point within a sphere centered at  $O$  and having a finite radius, a radius, that is, whose length in miles is expressed by any integer in  $(S)$ . And by saying that the surface of our infinite sphere is nowhere we mean that no point of the surface can be reached by traveling out from  $P$  any *finite* number, however large, of miles, by traveling, that is; a number of miles expressed by any number, however large, in  $(S)$ .

Here we have touched our primary goal: we have demonstrated that men and women whose education, in respect of space, has been of normal type, believe profoundly, albeit unawares, that the space of our universe is an infinite sphere of which the center is everywhere and the surface nowhere. Such is the beautiful conception,

the great conception—mathematically precise yet mystical withal and awful in its limitless reaches—which is ever ready to form itself, in the normally educated mind and there to stand a deep-rooted conscious conviction regarding the shape and the size of the all-embracing world.

Is the conception valid? Does the conviction correspond to fact? Is it true? It is not enough that it be intelligible, which it is; it is not enough that it be noble and sublime, which also it is. No doubt whatever is noble and sublime is, in some sense, true. For we mortals have to do with more than reason. Yet science, science in the modern technical sense of the term, having elected for its field the domain of the rational, allows no superrational tests of truth to be sufficient or final. We must, therefore, ask: are the dimensions and the figure of our space, in fact, what, as we have seen, Pascal asserts and the normally educated mind believes them to be? Long before the days of Pascal, back yonder in the last century before the beginning of the Christian era, one of the acutest and boldest thinkers of all time, immortal expounder of Epicurean thought, answered the question with the utmost confidence in the affirmative. I refer to Lucretius and his "*De Rerum Natura*." In my view that poem is the greatest and finest union of literary excellence and scientific spirit to be found in the annals of human thinking. I maintain that opinion of the work despite the fact that the majority of its conclusions have been invalidated by time, have perished by supersession; for we must not forget that, in respect of knowledge, "the present is no more exempt from the sneer of the future than the past has been." I maintain that opinion of the work despite the fact that the enterprise of Lucretius was marvelously extravagant; for we must not forget that the relative modesty

of modern men of science is not inborn, but is only an imperfectly acquired lesson. Well, it is in that great work that Lucretius endeavors to prove that our universe of space is infinite in the sense that we have explained. His argument, which runs to many words, may be briefly paraphrased as follows. Conceive that, starting from any point of space, you go out in any direction as far as you please, and that then you hurl your javelin. Either it will go on, in which case there is space ahead for it to move in, or it will not go on, in which case there must be space ahead to contain whatever prevents its going. In either case, then, however far you may have gone, there is yet space beyond. And so, he concludes, space is infinite, and he triumphantly adds:

Therefore the nature of room and the space of the unfathomable void are such as bright thunderbolts can not race through in their course though gliding on through endless tract of time, no nor lessen one jot the journey that remains to go by all their travel—so huge a room is spread out on all sides for things without any bounds in all directions round.

Such is the argument, the great argument, of the Roman poet. Great I call it, for it is great enough to have fooled all philosophers and men of science for two thousand years. Indeed only a decade ago I heard the argument confidently employed by an American thinker of more than national reputation. But is the argument really fallacious? It is. The conclusion may indeed be quite correct—space may indeed be infinite, as Lucretius asserts—but it does not follow from his argument. To show the fallacy is no difficult feat. Consider a sphere of finite radius. We may suppose it to be very small or intermediate or very large—no matter what its size so long as its radius is finite. By sphere, in this part of the discussion, I shall mean sphere-surface. Be good enough

to note and bear that in mind. Observe that this sphere—this surface—is a kind of room. It is a kind of space, region or room where certain things, as points, circle arcs and countless other configurations can be and move. These things, confined to this surface, which is their world, their universe of space, if you please, enjoy a certain amount, an immense amount, of freedom: the points of this world can move in it hither, thither and yonder; they can move very far, millions and millions of miles, even in the same direction, if only the sphere be taken large enough. I see no reason why we should not, for the sake of vividness, fancy that spherical world inhabited by two-dimensional intelligences conformed to their locus and home just as we are conformed to our own space of three dimensions. I see no reason why we should not fancy those creatures, in the course of their history, to have had their own Democritus and Epicurus, to have had their own Roman republic or empire and in it to have produced the brilliant analogues of our own Vergil, Cicero and Lucretius. Do but note attentively—for this is the point—that their Lucretius could have said about their space precisely what our own said about ours. Their Lucretius could have said to his fellow-inhabitants of the sphere: “starting at any point, go as far as ever you please in any straight line”—such line would of course (as we know) be a great circle of the sphere—and then hurl your javelin”—the javelin would, as we know, be only an *arc* of a great circle—“either it will go on, in which case, etc.; or it will not, etc.”; thus giving an argument identical with that of our own Lucretius. But what could it avail? We know what would happen to the javelin when hurled as supposed in the surface: it would go on for a while, there being nothing to prevent it. But

whether it went on or not, it could not be logically inferred that the surface, the space in question, is infinite, for we know that the surface is finite, just so many, a finite number of, square miles. The fallacy, at length, is bare. It consists—the fact has been recently often pointed out—in the age-long failure to distinguish adequately between *unbegrenzt* and *unendlich*—between *boundless* and *infinite* as applied to space. What our fancied Lucretius proved is, if anything, that the sphere is boundless, but not that it is infinite. What our real Lucretius proved is, if anything, that the space of our universe is boundless, but not that it is infinite. That a region or room may be boundless without being infinite is clearly shown by the sphere (surface). How evident, once it is drawn, the distinction is. And yet it was never drawn, in thinking about the dimensions of space, until in 1854 it was drawn by Riemann in his epoch-marking and epoch-making *Habilitationschrift* on the foundations of geometry.

What, then, is the fact? Is space finite, as Riemann held it may be? Or is it infinite, as Lucretius and Pascal deliberately asserted, and as the normally educated mind, however unconsciously, yet firmly believes? No one knows. The question is one of the few great outstanding scientific questions that intelligent laymen may, with a little expert assistance, contrive to grasp. Shall we ever find the answer? Time is long, and neither science nor philosophy feels constrained to haul down the flag and confess an *ignorabimus*. Neither is it necessary or wise for science and philosophy to camp indefinitely before a problem that they are evidently not yet equipped to solve. They may proceed to related problems, always reserving the right to return with better instruments and added light.

In the present instance, let us suppose,

for the moment, that Lucretius, Pascal and the normally educated mind are right: let us suppose that space is infinite, as they assert and believe. In that case the bounds of the universe are indeed remote, and yet we may ask: are there not ways to pass in thought the walls of even so vast a world? There are such ways. But where and how? For are we not supposing that the walls to be passed are distant by an amount that is infinite? And how may a boundary that is infinitely removed be reached and overpassed? The answer is that there are many infinities of many orders; that infinities are surpassed by other infinities; that infinities, like the stars, differ in glory. This is not rhetoric, it is naked fact. One of the grand achievements of mathematics in the nineteenth century is to have defined infinitude (as above defined) and to have discovered that infinities rise above infinities, in a genuine hierarchy without a summit. In order to show how we can in thought pass the Lucretian and Pascal walls of our universe, I must ask you to assume as a lemma a mathematical proposition which has indeed been rigorously established and is familiar, but the proof of which we can not tarry here to reproduce. Consider all the real numbers from *zero* to *one* inclusive, or, what is tantamount, consider all the points in a unit segment of a continuous straight line. The familiar proposition that I am asking you to assume is that it is not possible to set up a one-to-one correspondence between the points of that segment and the positive integers (in the sequence above given), but that, if you take away from the segment an infinitude (Aleph) of points matching all the positive integers, there will remain in the segment more points, infinitely more, than you have taken away. That means that the infinitude of points in the segment infi-

nitely surpasses the infinitude of positive integers; surpasses, that is, the infinitude of mile posts on the radius of our infinite (Pascal) sphere. Now conceive a straight line containing as many miles as there are points in the segment. You see at once that in that conception you have overleaped the infinitely distant walls of the Lucretian universe. Overleaped, did I say? Nay, you have passed beyond those borders by a distance infinitely greater than the length of any line contained within them. And thus it appears that, not our imagination, indeed, but our reason may gaze into spatial abysses beside which the infinite space of Lucretius and Pascal is but a meager thing, infinitesimally small. There remain yet other ways by which we are able to escape the infinite confines of this latter space. One of these ways is provided in the conception of hyperspaces enclosing our own as this encloses a plane. But that is another story, and the hour is spent.

The course we have here pursued has not, indeed, enabled us to answer with final assurance the two questions with which we set out. I hope we have seen along the way something of the possibilities involved. I hope we have gained some insight into the meaning of the questions and have seen that it is possible to discuss them profitably. And especially I hope that we have seen afresh, what we have always to be learning again, that it is not in the world of sense, however precious it is and ineffably wonderful and beautiful, nor yet in the still finer and ampler world of imagination, but it is in the world of conception and thought that the human intellect attains its appropriate freedom—a freedom without any limitation save the necessity of being consistent. Consistency, however, is only a prosaic name for a limitation which, in

another and higher realm, harmony imposes even upon the muses.

COLUMBIA UNIVERSITY

CLINICAL PSYCHOLOGY: WHAT IT IS  
AND WHAT IT IS NOT

ON an occasion like this<sup>1</sup> it would seem proper, representing as I do one of the newest of the sciences, that I address myself to some of the basic questions of this science. Perhaps the very first question with which one is confronted is simply this: "In view of the rapid multiplication of the sciences, by what right does clinical psychology lay claim to an independent existence?" That is a question which may perturb some sensitive minds, but it does not disconcert the clinical psychologist, for he regards the question as perfectly legitimate and capable of satisfactory answer.

It is just and proper that a new claimant to membership in the family of sciences should be required to present her creden-

tials. It is a natural human trait to challenge or contest the claims of a newcomer. It has ever been thus. Every branch of knowledge before winning recognition as an independent science has been forced to demonstrate that it possesses a *distinct and unique body of facts* not adequately treated by any other existing science; or that it approaches the study of a *common body* of facts from a *unique* point of view, and with methods of its own. Psychology, biochemistry, dentistry, eugenics, historiometry and many other sciences have been thus obliged to fight their way inch by inch to recognition as independent sciences. It is not long since physiology claimed psychology as its own child and stoutly contested her rights to existence; nor is it long since medicine denied any right to independent existence to dentistry. It is no surprise that a number of sciences now claim clinical psychology as part and parcel of their own flesh and blood, and that they deny her the right to "split off from the parent cell" and establish an un-nursed existence of her own. Just as nature abhors a vacuum, so science abhors the multiplication of sciences; just as the big corporation octopus in the industrial world tries to get monopolistic control of the sources of production and distribution, so the various sciences, naturally insatiable in their desire for conquest, attempt only too often to get monopolistic control of all those elements of knowledge which they may be able to use for their own aggrandizement, whether or not they have developed adequate instruments for scientifically handling those elements.

Clinical psychology, however, is quite ready to contest the attempts to deprive her of her inalienable rights to the "pursuit of life and happiness." Fundamentally, she bases her claims to recognition as an independent science on the fact that

<sup>1</sup>Substance of an address delivered before the Conference on the Exceptional Child, held under the auspices of the University of Pittsburgh, April 16, 1912. Lest misapprehensions arise, it should be clearly understood that in this discussion I am concerned only with the relation of *clinical psychology to mentally exceptional school children*; and that I distinctly recognize a different type of exceptional children, namely, the *physical defectives*. The physical defectives should be examined by skilled pediatricians. The clinical psychologist is interested in physically exceptional children if they manifest mental deviations. Moreover, while I hold that the psycho-clinical laboratories must become the clearing houses for all types of *mentally or educationally exceptional children* in the schools, nearly all mentally exceptional children should be given a physical examination by consulting or associated medical experts. Physical abnormalities should, of course, be rectified, whether or not it can be shown that they sustain any causal relation to any mental deviations which may have been disclosed in the psycho-clinical examination. They may claim treatment in their own right.

she *does* possess a unique body of facts not adequately handled by any existing science, and that she investigates these facts by methods of her own. These facts consist of *individual mental variations*, or the phenomena of *deviating or exceptional mentality*. In other words, clinical psychology is concerned with the *concrete* study and examination of the behavior of the *mentally exceptional individual* (not groups), by its own methods of observation, testing and experiment.

In the study or examination of individual cases, the clinical psychologist seeks to realize four fundamental aims:

1. *An Adequate Diagnosis or Classification*.—He attempts to give a correct description of the nature of the mental deviations shown by his cases; he tries to determine whether they are specific or general, whether they affect native or acquired traits; he attempts to measure by standard objective tests the degree of deviation of various mental traits or of the general level of functioning; he seeks to arrive at a comprehensive clinical picture, to disentangle symptom-complexes and to reduce the disorders to various reaction types.

2. *An Analysis of the Etiological Background*.—His examination is bent not only on determining the present mental status of the case, but on discovering the causative factors or agents which have produced the deviations—whether these factors are physical, mental, social, moral, educational, environmental or hereditary. In order to arrive at a correct etiology the psycho-clinician makes not only a cross-section analysis of the case, but also a longitudinal study of the evolution of the deviation or symptom-complex. Therefore he does not limit himself merely to a psychological examination, but requires a dento-medical examination and a sociological and hereditary examination. The physical examination

should be made by experts in dentistry and in the various specialties in the field of medicine. The psycho-clinician, however, should be so trained in physical diagnosis that he can detect the chief physical disorders, so that he can properly refer his cases for expert physical examination.

3. A determination of the *modification* which the disorder has wrought in the *behavior of the individual*. He should determine what its consequences have been: what effects it has had upon his opinions, beliefs, thoughts, disposition, attitudes, interests, habits, conduct, capacity for adaptation, learning ability, capacity to acquire certain kinds of knowledge or various accomplishments, or to do certain kinds of school work. He should seek to locate the conflicts between instincts and habits which may have been caused by the deviations.

4. The determination of the *degree of modifiability* of the variations discovered. Can the deviations be corrected or modified, and if so to what extent and by what kinds of orthogenic measures? A clinical psychologist is no less a scientific investigator than a consulting specialist; he diagnoses in order to prognose and prescribe. His aim first and last is eminently practical.

#### BASIS OF SELECTION OF CASES

The clinical psychologist selects his cases not so much on the nature of the cause of the deviations as on the nature of the deviations themselves, and the nature of the treatment. He is interested in cases which, first of all, depart from the limits of mental normality. *Exceptional mentality*, or, if you please, *mental exceptionality*, is his first criterion. In the second place, he is interested in those cases in which the nature of the treatment—the *process of righting* the mental variations, of straightening out the deviations, the orthogenesis—

is wholly or chiefly or partly *educational*. In the term educational I include training of a hygienic, physiological (in Seguin's sense), pedagogical, psychological, sociological or moral character.

#### GROUPING OF CASES

It is thus evident that the clinical psychologist may group his cases into two main classes.

A. Those in which the *mental variations are fundamental* or primary, and the physical disabilities only accessory or sequential. With these cases the treatment must be primarily educational and only secondarily medical. What types of children are included in this group?

I. *Feeble-minded Children*.—Feeble-mindedness formerly was regarded as an active disorder—a disease—and was accordingly treated exclusively medically. The theory of causation was wrong and so the results were unsatisfactory. Since the year 1800 (Itard, the apostle to the feeble-minded) and particularly since the year 1837 (Seguin, the liberator of the feeble-minded), it has become increasingly apparent that feeble-mindedness is an arrest of development; and accordingly since that time the condition has been primarily educationally treated instead of medically. This change in point of view has revolutionized the treatment of the feeble-minded. The person who did most to ameliorate their condition is Seguin, whose method, almost entirely educational, has served as the model for the effective institutional work for the feeble-minded done since his day, although we have outgrown various details of his system. Moreover, it served as the chief inspiring force for the constructive orthogenic work done for the feeble-minded within the last decade or so by Montessori. She, herself a physician, but with special training in psychology

and pedagogy, tells us that in 1898 as a result of a careful study of the problem of feeble-mindedness she became persuaded that the problem was primarily a pedagogical and not a medical one. It is granted without question, of course, that there is a medical side to the care of the feeble-minded just as there is a medical side to the care of the normal child. Nay, owing to the heightened degree of susceptibility to disease and accidents found among the feeble-minded, the medical side looms larger in the care of the feeble-minded than in the care of normals. Indeed, no institution for the feeble-minded can be properly organized without an adequate staff of medical experts; but fundamentally the problem of the amelioration of the lot of feeble-minded children is an educational one—their hygienic, pedagogical and moral improvement, as well as their elimination by the method of colonization or sterilization.

II. *Retardates*, technically so-called—of which there are probably on a conservative estimate 6,000,000 in the schools of the United States. Some of these are retarded (1) merely pedagogically in a relative sense—relative to an *arbitrary curricular standard*. Many children do not fit the standard, because the standard itself is off the norm. It is largely a case of a misfit curriculum instead of a misfit child. So far as this class of misfits is concerned the problem is simply one of correct adjustment of the pedagogical demands of the curriculum.

A considerable percentage of the retardates, however, are retarded because of (2) *genuine mental arrest of development*. They are as truly arrested or deficient as the feeble-minded, but to a *lesser extent*. The difference is a *quantitative* and not a qualitative one, and the problem of correc-

tion consists fundamentally in providing a right educational regimen.

Then there is (3) a smaller proportion of retardates who are mentally retarded because of *environmental handicaps*, such as bad housing, home and neighborhood conditions, bad sanitation, lack of humidity, lack of pure air or excessive temperature in the schoolroom, vicious or illiterate surroundings, frequent moving or transfer, emigration which may cause linguistic maladaptation, etc. With such retardates the problem is partly sociological, partly hygienic, and partly pedagogical.

We have a final group of children (4) who are mentally retarded because of some *physical defect*. With children of this type the problem is partly medical and partly educational. The first efforts made in behalf of such children should be medical and hygienic. Undoubtedly the removal of physical handicaps will restore some pupils to normal mentality, while in the case of other pupils the results will be negative. Unfortunately there are very few scientific studies available of the orthophrenic effects of the correction of physical defects.<sup>2</sup> Many of the studies in this field have a questionable value because of the obvious, but evidently unconscious, bias of the investigators. Some desire to show favorable results and, therefore, unconsciously select only the favorable cases; others are swayed by the opposite motive and accordingly tend to select the negative cases. Hence, at the present time we find considerable diversity of opinion as to the orthogenic influences of the correction of

physical disorders. The opinion of John J. Cronin, M.D., probably approximates the truth:

The successes simply mean that a large number of children were perfect except for some one abnormality. . . . The alleviation of any single kind of physical handicap is merely one step towards the successful result sought, and many other factors must obtain before some measure of success is assured.

Likewise A. Emil Schmitt, M.D.:

It should constantly be borne in mind that if every physical defect has been successfully removed the mental unbalance or deficiency can remain unaltered, inasmuch as it was primarily a mental defect and can be reached only by methods of education or psychological treatment.

While I am quite convinced that all mentally retarded children should undergo a careful physical examination, and that such physical corrective measures should be applied as are indicated by expert medical opinion, yet it needs to be re-emphasized that the removal of a physical disability is frequently only the first step toward restoration. If the child has fallen behind pedagogically or mentally, he will in many cases need special pedagogical attention if he is to catch step with the class procession; moreover, after a certain critical age has been passed the removal of physical obstructions exercises only a slight orthophrenic influence, and the reestablishment of effective mental functioning, if it can be done at all, will require the prolonged application of a special corrective pedagogy.

III. *The Super-normals*.—Both of the above types of children come on the minus side of the curve of efficiency. On the other side we find the plus deviates—the bright, brilliant, quick, gifted, talented, precocious children. These children may present no peculiarities on the physical side, if we except the type of nervously unstable, precocious children. With the supernormal

<sup>2</sup> However, see an attempt at the scientific measurement of the orthophrenic effects of the correction of dental defects in J. E. Wallace Wallin's "Experimental Oral Euthenics," *The Dental Cosmos*, 1912, pp. 404-413, 545-566. Also, "Experimental Oral Orthogenics," *The Journal of Philosophy, Psychology and Scientific Methods*, 1912, pp. 290-298.

child the problem is almost entirely an educational one: the introduction of schemes of flexible grading; of fast, slow and normal sections, and of supernormal classes; providing special opportunities for doing specialized work, and a special pedagogy, which should probably be as largely negative as positive. If there is any one child in our scheme of public education which has been neglected more than any other, it is the child of unusual talents. A nation can do no higher duty by its subjects than to provide those conditions which will rescue its incipient geniuses from the dead-level of enforced mediocrity.

IV. *Speech defectives*, particularly the two and one half per cent. (approximately) of stutterers and lispers who encumber our classes. In few fields of scientific research is it possible to find such astonishing diversity of so-called expert opinion as on the question of the causation of stuttering (or stammering). It is claimed to be a gastric, pneumogastric, lung, throat, lip, brain, hypoplastic, nervous and mental disorder. It is said to be a form of epilepsy, a form of hysteria, and a form of mental strife, or repression, between latent and manifest mental contents. Moreover, few writers show such a consummate genius for self-contradiction as writers on stuttering. Before me lies a reprint of a recent dissertation on the "Educational Treatment of Stuttering Children." The writer begins by saying that stuttering is a "pathological condition," a disease, and that therefore its treatment belongs to a specialist on diseases. The disease appears, however, on the second page to be merely "a purely functional neurosis," while on the last page the trouble is nothing more than a "mental one," caused by influences acting on the mind. As a matter of fact, the treatment which the writer recommends is through

and through educational and largely psychological. It consists of certain physical exercises, designed not so much to strengthen certain organs as to win the patient's interest and restore his self-confidence; and certain psychotherapeutic and hypnotic exercises.

Waiving for the time being the nature of the cause, we can agree on one thing; namely, that the methods of treating stuttering (and lipping) which have been proved effective are almost exclusively educational. Many of the neurotic symptoms found in the stutterer are the results of mental tension and will disappear with the correction of the stuttering.

V. *Incipient psychotics*, or children who show developmental symptoms of mental disorders or mental alienation. Here we meet with the same controversy between the advocates, on the one hand, of a *somatogenic* theory, and, on the other hand, of a *psychogenic* theory of causation. While it must be admitted that many of the psychoses are certainly organic, others almost as certainly are functional and are produced by idiogenic factors (a view entertained by such well-known psychiatrists as Meyer, Freud, Janet, Dubois, Jones, Prince). Now, irrespective of whether the cause is chiefly physical or mental, it is being recognized by a number of the leading present-day psychiatrists that drug treatment for the majority of the insane, whether juvenile or adult, is secondary to the educational treatment. Instead of merely prescribing physical hygiene for the insane, leading alienists are now prescribing mental hygiene. The cure is being conceived in terms of a process of reeducation. Moreover, so far as concerns the mentally unstable child in the schools, the chief reliance is obviously on hygienic and educational guidance.

B. Cases in which the *physical devia-*

tions are fundamental or primary, and the mental variations sequential, but the remedy partly or chiefly educational. Here we include malnutrition, rickets, marasmus, hypothyroidism, tuberculosis, heart trouble, chorea and similar diseases. In all of these the treatment must be primarily medical, although there should be a special temporary educational regimen for these children. This group also includes the blind and the deaf. But here the treatment is almost wholly educational. The physical defects are incurable, but the mental defects can be partly overcome by proper compensatory educational treatment. The epileptic also must be added to this group. Epilepsy is evidently an active disorder or disease process, although the pathology is wrapped in the deepest obscurity. The epileptics appear like purely medical cases. The medical aspect certainly is important, but the records show that only from 5 to 10 per cent. are curable, and that the attacks can be as readily modified or regulated in most cases by proper hygienic treatment as by drug medication or surgical interference. Even with these unfortunates it can be said that the best results come from a proper medico-educational régime—colonization, out-door employment, industrial schooling, bathing, etc.

#### SUMMARY OF IMPORTANT CONCLUSIONS

We are thus brought to the two following conclusions:

1. There is a set of unique facts—facts of individual mental variation—which no existing science has adequately treated. It is with these facts that the work of the clinical psychologist is concerned. Just as psychology became an independent science by demonstrating that it possessed a legitimate claim to a unique world of facts, so clinical psychology is ready to make her declaration of independence and dedicate

herself to the investigation of a body of facts—facts of individual mental variation—not hitherto adequately handled by any existing science. It is concerned with the study of individual cases of deviate mentality, particularly with those types which are amenable to improvement or correction by psycho-educational processes.

2. The proper handling of these cases, whether for purposes of examination, recommendation or prescription, can only be done by a *psycho-educational specialist* who possesses a technical knowledge of educational and child psychology, of child hygiene, of the science and art of education, and of various classes of mental defectives or deviates. He should possess a thorough grounding in clinical procedure, particularly in the methods of clinical psychology, while he must also have a certain amount of training in pediatrics, physical diagnosis, neurology and psychiatry. He must be thoroughly skilled in the differential pedagogy appertaining to various types of mentally exceptional children.

*C. The Relations of Clinical Psychology—Some Affirmations and Denials.*—There is a number of sciences with which clinical psychology is, will be, or should be, closely related, but which are not synonymous with clinical psychology.

1. Clinical psychology is not the same as *psychopathology*. The typical alienist is concerned with the study and treatment of mental disorders (technically called psychoses); the clinical psychologist, on the other hand, is concerned *particularly* (though not solely) with the study of *plus* and *minus deviations* from normal mentality. The alienist works chiefly with adults, the clinical psychologist with children. Few alienists possess any expert knowledge of the literature bearing on child or educational psychology, mental deficiency, retardation or acceleration,

stuttering or lisping, special pedagogy or psycho-clinical methods of testing. An alienist accordingly is not to be considered a specialist on the mentally exceptional child in the schools unless indeed he has supplemented his general medical and psychiatric education with a technical study of the psychological and educational aspects of the problem. The alienist of the future will certainly have to secure a different preparation from that now furnished in the medical schools, if he is to enter the field of pedagogic child study.

Before me lies the report of the department of medical inspection of a large school system. Six hundred retarded children were examined in this department, which is in charge of an alienist, who, as I am told, is an expert on the questions of *adult insanity*, but who has no specialized preparation in the psychology and pedagogy of the mentally defective child. Of these children 49.7 per cent. are recorded as feeble-minded. Applying this figure to the 6,000,000 retardates of the public schools of the country, we get a total feeble-minded school population of 3,000,000. This figure, it need scarcely be said, is monstrously absurd. It is fully ten times too large. Feeble-mindedness and backwardness in children, it must be said, are distinct problems from mental alienation, and require for their satisfactory handling a specialist on mentally deviating children. A high grade feeble-minded child can not be identified merely by some rule-of-thumb system of intelligence tests. Feeble-mindedness involves more than a given degree of intelligence retardation. At the same time, lest I be misunderstood, it should be specially stated that psychiatry and clinical psychology will be mutually helped by a closer union. Clinical psychology has many important facts and a valuable experimental technique to offer to psycho-

pathology, and psychopathology in turn is able to contribute facts of great value, and more particularly an effective clinical method of examination, to clinical psychology. As the idiogenic conception of the causation of various psychoses wins greater recognition, clinical psychology will become more and more indispensable to the psychiatrist. It is certain that the efficiency of the clinical psychologist will be greatly increased by a study of mental alienation—not a study of texts on psychiatry, but a first-hand study in institutional residence of individual cases. Any one intending to do psycho-clinical work with mentally deficient children certainly should spend a year or two in residence at institutions for feeble-minded, epileptic and alienated children. The clinical psychologist should be prepared to recognize cases of incipient mental disorder, so that he will be enabled to select these cases and refer them to a psychiatric specialist for further examination.

2. Clinical psychology is not *neurology*. There are important neurological aspects involved in the study of mentally exceptional children. Mental arrest can be largely expressed in terms of neurological arrest, and a clinical psychologist should have a first-hand knowledge of nerve signs and a practical acquaintance with the methods of neurological diagnosis. His knowledge of neurology should be sufficient to enable him to pick out suspected nervous cases and refer them for expert examination by a neurologist. However, it must be emphasized that neurology touches only one side—though an extremely important side—of the problem of exceptional mentality.

3. Clinical psychology is not synonymous with *general medicine*. The average medical practitioner certainly knows far less about the facts of mental variation in

children than either the psychiatrist or neurologist or even the class-room teacher. This fact should occasion no surprise when it is stated that the study of psychology as a science has been practically ignored in the medical curricula throughout the country. The clinical psychologist, however, as I have already said, should be able to detect the chief physical defects found in school children, so that if the laboratory of the clinical psychologist assumes the function of a clearing house for the exceptional child he may be able to refer all suspected cases to proper medical clinics for expert examination and treatment.

4. Clinical psychology is not *pediatrics*. To be sure, the pediatrician deals with children. But his attention is focused on the physical abnormalities of infants; his interest in the phenomena of mental exceptionality is liable to be incidental or perfunctory. In fact, one may read some texts on pediatrics from cover to cover without so much as arriving at a suspicion that there is a body of unique facts converging on the phenomena of departure from the limits of mental normality which require intensive, specialized, expert study and diagnosis. So far as the physical ailments or disabilities of young children are concerned the pediatrician is in a position to render valuable service to the psycho-clinician; likewise so far as concerns the mental deviations of children the psycho-clinician is able to render valuable aid to the pediatrician. But one must not confuse pediatrics with clinical psychology.

5. Clinical psychology is not the same as *introspective, educational or experimental psychology*. It differs from these in its method, standpoint and conceptions. While the clinical psychologist should be grounded in introspective and, especially, experimental, educational and child psychology, expertness in these branches of

psychology does not in itself confer expertness in practical psycho-clinical work. Such expertness comes only from a technical training in clinical psychology and from a first-hand prolonged study by observation, or experiment, or test of various kinds of mentally exceptional children, particularly the feeble-minded, the epileptic and the retarded. The skilled specialist in experimental or educational psychology or experimental pedagogy, is no more qualified to *clinically* examine mental cases, than is the skilled zoologist, physiologist or anatomist able to *clinically* examine physical cases. Clinical work, both in psychology and medicine, requires clinical training. The assumption that any psychologist or educationist is qualified to do successful psycho-clinical work, after learning how to administer a few mental tests, is preposterous and fraught with the gravest consequences. Clinical psychology can have no standing in the professions as long as we permit this absurd notion to prevail.

J. E. WALLACE WALLIN

PSYCHOLOGICAL CLINIC,  
UNIVERSITY OF PITTSBURGH

#### PENSIONS IN THE ROCKEFELLER INSTITUTE

PENSIONS for its members and associate members have been provided by the governing boards of the Rockefeller Institute for Medical Research, and have been financially secured by the generosity of Mr. John D. Rockefeller, who has with this purpose in view increased the endowment of the institute by a gift to it of securities amounting to about \$500,000 in value. The pension rules which have been adopted provide three-quarters-pay pensions for members of the institute retiring at the age of 65 after fifteen or more years of service, and pensions of from one half to three quarters of full pay, according to the length of service, for members and associate members who retire at 60 years of age. There is also a provision for total disability after ten

years of service, and for widows and orphaned children, at one half the scale upon which members of the staff are pensioned.

#### SCIENTIFIC NOTES AND NEWS

At its commencement exercises last week Columbia University conferred its doctorate of science on Colonel William C. Gorgas, Assistant Surgeon General U. S. A., and Dr. Alexis Carrel, Rockefeller Institute for Medical Research.

THE Medical Society of London, at its meeting on May 19, elected Sir David Ferrier, F.R.S., president, in succession to Sir Watson Cheyne.

DR. V. F. K. BJERKNES, professor of geophysics in the University of Leipzig, and Dr. Hugo Hergesell, president of the International Commission for Scientific Aéronautics, Strasbourg, have been elected honorary members of the Royal Meteorological Society.

PROFESSOR GEORGE F. SWAIN, professor of civil engineering in the Graduate School of Applied Science at Harvard University, has been chosen chairman of the Boston Transit Commission to succeed the late George G. Crocker.

PROFESSOR CHARLES J. SMITH, for forty-three years head of the department of mathematics in Western Reserve College and Adelbert College, has presented his resignation and will retire from the faculty at the close of the present college year. He served as professor of mathematics and Perkins professor of natural philosophy and astronomy in Western Reserve College from 1870 to 1882, and as professor of mathematics in Adelbert College from 1882 to the present.

ASSISTANT PROFESSOR J. E. READHIMER, superintendent of experiment fields at the University of Illinois since 1901, has entered on his duties as agricultural adviser in Kane County, Illinois. Professor Readhimer began his work at the university when there were no experiment fields in the state outside of Urbana. He has had a part in a great agricultural development in Illinois. As superinten-

dent he has been intimately connected with the development of the experiment fields. He has seen them increase from one (in Urbana) to thirty-five, scattered over the entire state.

GARDNER C. BASSET, Ph.D., of the Johns Hopkins University, in psychology (1913), has been appointed research assistant in the Eugenics Record Office of the Station for Experimental Evolution at Cold Spring Harbor, and will continue the work on the intelligence of inbred white rats begun at Johns Hopkins.

DR. HARRISON J. HUNT, of Island Falls, Maine, has been appointed surgeon to the Crocker Land Expedition which is leaving for the north polar regions on July 2 next, under the auspices of the American Museum of Natural History, the American Geographical Society and the University of Illinois. Dr. Hunt is a graduate of Bowdoin College and medical school and has had eight years' private practise.

THE C. M. Warren committee of the American Academy of Arts and Sciences has increased to two hundred dollars the award to Professor E. W. Washburn, University of Illinois, for his work on the design of an adiabatic calorimeter. Professor H. B. Byers, University of Washington, has recently published two papers on the passivity of iron, dealing with researches which were in part made possible by grants from the Warren fund. This fund was bequeathed to the academy "for the encouragement and advance of research in the science or field of chemistry" and the committee in charge is glad to know of investigations which may properly be aided by it. Professor H. P. Talbot, Massachusetts Institute of Technology, Boston, Mass., is chairman of the committee.

DR. F. D. BARKER, of the department of zoology of the University of Nebraska, has been voted a grant by the trustees of the Bache fund to enable him to continue his study of the parasitic fauna of the Bermudas. Dr. Barker will spend the latter part of this summer and next summer collecting material at Bermuda.

DR. A. C. ABBOTT, Pepper professor of hygiene and bacteriology, University of Pennsylvania, has been appointed a delegate to the fourth International Congress of School Hygiene, to be held at Buffalo, August 25 to 30, next, to represent the University of Pennsylvania and the American Physiological Society.

MR. N. E. HANSEN, secretary of the South Dakota State Agricultural Society, has started on his fourth expedition to Siberia, to gather seed of the Siberian alfalfas which he brought over in 1906 for the first time.

PROFESSOR B. E. LIVINGSTON will spend the summer at the Desert Laboratory of the Carnegie Institution, at Tucson, Arizona, where he may be addressed from June 20 to September 20.

PROFESSOR W. A. HENRY, emeritus professor of agriculture at the University of Wisconsin, and for fifteen years dean of the College of Agriculture, is again at the university after a five months' absence. He is planning the preparation of a new book on agriculture.

DR. E. C. SCHROEDER, pathologist of the Bureau of Animal Industry, delivered the concluding lecture of the annual series under the auspices of the Ohio State University chapter of the Society of Sigma Xi upon the topic, "Relation of Animal to Human Tuberculosis."

DR. OSCAR RIDDLE, of the Carnegie Institution, lectured on May 5 under the auspices of the Cornell Chapter of Sigma Xi on "A Relation between the Storage Metabolism of Ova and the Experimental Control of Sex."

THE Croonian lecture before the Royal Society was delivered by Dr. Robert Broom, keeper of vertebrate paleontology in the South African Museum, on June 5. The subject was "The Origin of Mammals."

THE mathematical works of the late Henri Poincaré are to be published by the firm of Gauthier-Villars, under the auspices of the minister of public instruction and the Paris Academy of Sciences.

PROFESSOR FRANCIS T. HAVARD, associate professor of mining and metallurgy at the University of Wisconsin, died at Madison re-

cently from pneumonia. He was thirty-five years of age and was a native of Australia. He attended universities in Australia and Germany and later had charge of mining interests in South America, Africa and Montana. He became associated with the University of Wisconsin in the fall of 1909.

PROFESSOR HEINRICH WEBER, of Strasburg, died of apoplexy on May 17. He is principally known for his profound work in algebra and at various times was rector of the universities of Königsberg, Marburg and Strasburg. His wife, who died a few years ago, translated Poincaré's "La valeur de la science" into German.

THE regular annual meeting of the American Chemical Society will be held in Rochester, N. Y., September 9-12, inclusive.

A PARTY of advanced students from the department of geology of the University of Illinois, under the leadership of Dr. John L. Rich, left on June 12 for a two-weeks' geological and geographical excursion through neighboring states. The party planned to proceed east to Richmond, Indiana, and Hamilton, Ohio, where a study will be made of the physiography of the district devastated by the recent floods of the Miami River, thence to Cincinnati. From Cincinnati the party will proceed south into the blue grass district of central Kentucky, west to Mammoth Cave, where a stop of two days will be made, and then return to Urbana through Kentucky and Indiana.

ON May 28 an informal meeting was held in the Peabody Museum, Harvard University, and the sod was turned to begin the building of the addition to the Peabody Museum which will complete the entire University Museum as originally planned. A short address written by Professor F. W. Putnam was read by Dr. Charles Peabody. Professor Putnam, unfortunately absent on account of illness, recalled the first ceremony in connection with the beginning of the museum when Governor Banks cut the sod, Professor Louis Agassiz turned it over and Mrs. Agassiz put it into the wheelbarrow. In the present exercises

President Lowell cut the sod which was lifted by Mrs. Henry L. Higginson, a daughter of Professor Louis Agassiz and a sister of the late Professor Alexander Agassiz, '55. After this, George R. Agassiz, '84, and Maximilian Agassiz, '89, followed in turn, as well as a number of other officers of the different departments of the University Museum. The money for the addition has been raised by contribution from friends interested not only in the Peabody Museum, but in the University Museum. The building will be pushed forward with energy and it is hoped that the new space for the collections will be available in the course of nine or ten months.

THE tenth annual session of the Puget Sound Marine Station will convene at Friday Harbor, Washington, on June 23, and will continue for a period of six weeks. The courses to be offered will be as follows: algology, R. B. Wylie, University of Iowa; plant ecology, A. R. Sweetser, University of Oregon; elementary botany, William Moodie, Washington State Normal; elementary zoology, H. B. Duncanson, Nebraska State Normal; general ecology, H. S. Brode, Whitman College; embryology of invertebrates, Wm. J. Baumgartner, University of Kansas; ichthyology, E. V. Smith, University of Washington; advanced ecology, Trevor Kincaid, University of Washington; plankton, John F. Bovard, University of Oregon. Facilities will also be offered for research along botanical and zoological lines. The systematic survey of the local fauna which has been in progress for several seasons will be continued by further deep-water exploration. The director of the station, Professor Trevor Kincaid, of the University of Washington, will be glad to give more extended information to persons planning to visit the laboratory.

#### UNIVERSITY AND EDUCATIONAL NEWS

MR. ANDREW CARNEGIE has undertaken to provide a million dollars for the medical department of Vanderbilt University. Of this sum \$200,000 would be given the university immediately for the erection and equipment of laboratories. The income from the re-

maining \$800,000 would be paid annually for the support of the department through the Carnegie Corporation. A condition of the donation provides that the direction of the educational and scientific work of the department be committed by the board of trustees to a small board of seven members, three of whom shall be eminent in medical and scientific work.

MESSRS. JAMES B. and BENJAMIN N. DUKE have given \$800,000 more to Trinity College in North Carolina. The college thus met the \$150,000 promised by the Rockefeller Foundation and has added one million dollars to its endowment.

Governor Sulzer has signed a bill appropriating \$250,000 for a building for the State College of Agriculture at Syracuse University. Plans for the building are in the hands of the state architect and ground for the building will be broken early in the summer. The building will be located on the western end of the university campus, and when completed will be the largest and best equipped forestry building in the United States. Provision will be made in the basement of the building for laboratories for timber-testing and for investigations in the production of paper pulp and in the destructive distillation of timber. That is, there will be in a simple and miniature way complete paper-making and acid plants. With this will be a very complete wood-working shop where students may get acquainted with woods from the builder's standpoint. Besides offices, class-rooms and laboratories, there will be an auditorium on the third and fourth floors with a seating capacity of 1,000. Such closely related lines as forest botany, forest zoology and forest entomology will be taken care of in especially equipped laboratories.

THAT the University of Wisconsin has 5,970 students at Madison this year and 5,523 enrolled in correspondence-study courses—a total of 11,493—is shown by the new catalogue of the university which came from press this week. Every college in the university except the College of Engineering shows a gain. The College of Agriculture, with a gain of 108 students over last year's enrollment of 743,

making this year's total enrollment 851, shows the largest increase of any division of the university. The College of Letters and Science has an enrollment of 2,528, as compared with 2,504 last year. The course in pharmacy in this college has increased from 38 to 44, and the Medical School from 57 to 66. The course for normal school graduates has a registration of 66 as compared with 58 last year. The course in commerce has 335 students, a loss of 5, while the course in chemistry has 77 students, a loss of 11. The Law School with 167 students has 9 more students than last year. The Library School has 36 students, two more than last year, and the largest number that can be accommodated with the present facilities. The School of Music has a total of 418 students. The College of Engineering has 678 students, a loss of 50. This loss is largely in the present freshman class, which has 49 students less than that of last year. The Graduate School this year numbers 394, a gain of 17. The faculty of the university consists of 624 members, of whom 95 are full professors, 45 associate professors, 111 assistant professors, 21 special lecturers, 201 instructors and 152 assistants.

JOHN L. ULRICH, Ph.D. (Johns Hopkins University '13), has been appointed instructor in physiological psychology in the Catholic University of America.

DR. W. J. V. OSTERHOUT has been promoted to be professor of botany at Harvard University; Dr. P. W. Bridgman has been promoted to be assistant professor of physics.

DR. B. M. ALLEN, assistant professor of anatomy in the University of Wisconsin, has been chosen by the board of administration of the University of Kansas to be head of the department of zoology, succeeding Professor C. E. McClung, who a year ago became head of the department of zoology in the University of Pennsylvania. Promotions have been made as follows: F. H. Billings, from associate professor to professor of bacteriology; N. P. Sherwood, from instructor to assistant professor of bacteriology; W. H. Twenhofel, from assistant professor to associate professor of

geology; T. T. Smith, from instructor to assistant professor of physics; R. K. Yodng, from instructor to assistant professor of physics and astronomy; W. J. Baumgartner, from assistant professor to associate professor of zoology; F. C. Dockeray, from instructor to assistant professor of psychology; H. W. Josselyn, from assistant professor to associate professor of education; H. A. Rice, from associate professor to professor of civil engineering; F. H. Sibley, from assistant professor to associate professor of mechanical engineering.

THE corporation of the Massachusetts Institute of Technology, at its meeting on June 6, confirmed the following promotions and appointments in the instructing staff of the institute: Dr. J. Arnold Rockwell appointed medical adviser in place of Dr. F. W. White. Associate Professor F. A. Laws, promoted to professor of electrical engineering. The following assistant professors are promoted to the grade of associate professor: Earle B. Phelps, research in chemical biology; S. P. Mulliken, organic chemical research; M. S. Sherrill, theoretical chemistry; G. E. Russell, civil engineering; Ervin Kenison, drawing and descriptive geometry; N. R. George and L. M. Passano, mathematics; M. deK. Thompson, electrochemistry; L. E. Moore, civil engineering. Two instructors were promoted to the grade of assistant professor: Edward Mueller, inorganic chemistry; J. W. Howard, topographical engineering. A number of assistants have been promoted to the grade of instructor, namely, N. S. Marston, electrical engineering; Duncan MacRae, inorganic chemistry, replacing C. R. Cressy; Dean Peabody, mechanical engineering; W. H. Wengert, mechanical engineering; W. J. Murray, analytical chemistry, replacing Mr. Fallon, and C. K. Reiman, inorganic chemistry. Assistant J. M. Livingston has been made research associate in applied chemistry. The following are new appointments to assistantships: Edward A. Ingham, biology; Robert D. Bonney, Warren E. Glancy, Leon W. Parsons and Charles S. Venable (half time), analytical chemistry, replacing E. T. Marceau, P. M. Tyler, C. K. Reiman (pro-

moted) and J. A. Gann, respectively; F. W. Lane and Philip B. Terry, organic chemistry, replacing W. J. Murray and J. W. Livingston, promoted; Arthur E. Bellis and Charles L. Burdick, theoretical chemistry, replacing B. F. Brann and Duncan MacRae, promoted; Lester F. Hoyt, water analysis, replacing W. J. Daniels; Francis H. Achard, Henry C. Harrison and Russell E. Leonard, electrical engineering, replacing D. M. Terwillinger, J. P. King and H. G. Jenks; Edgar W. Taft, military science, replacing A. J. Pastence; John P. Constable, naval architecture, replacing R. B. Pulsifer; Warren K. Green and William G. Horsch, physics, replacing Mr. Wells and Mr. Wilkins; Millard W. Merrill, electro-chemistry, replacing Mr. Gonzales; R. G. Daggett, research assistant in sanitary chemistry; George Richter and W. B. Van Arsdell, research assistants in applied chemistry; H. F. Thomson, assistant to the director of the research laboratory of electrical engineering and part-time instructor in electrical engineering; Robert E. Rogers, instructor in English; Thomas S. Holden, part-time instructor in mathematics; Clarence Hale Sutherland, instructor in civil engineering, replacing Mr. Bradbury, resigned; Ferdinand H. Pendleton, Jr., assistant in technical analysis, replacing Mr. Bishop.

#### DISCUSSION AND CORRESPONDENCE

##### THE CONSTITUENCY OF THE EXPERIMENT STATION

IN a communication to *SCIENCE* for May 9, page 708, Dr. Raymond Pearl, after stating that theoretically it is a primary function of the state experiment stations to conduct researches of a fundamental character which shall be calculated to discover basic natural laws, says:

Actually, with a few rare and partial exceptions, experiment stations do nothing of the sort. On the contrary, what they do engage in is experimental work of a kind carefully calculated to make as strong an appeal as possible on the basis of its supposed "practicality" to the scientifically uneducated and uncritical farmers who make up its constituency. The experiment-station investigator in many cases (though happily not in all, as I

am able personally to affirm after five years' experience in Maine) is compelled by force of circumstance over which he has no control to supplicate the great goddess truth with one ear closely applied to the ground in order that he may catch the first and faintest murmur of "what the public wants." If he has the temerity to venture upon a piece of research for which by the most extreme sophistry no evidence of immediate practicality can be adduced, he must do the work sub rosa and publish the results in such place that by no possible chance can the constituency ever learn of it.

It would be impossible to pack into the same space a greater amount of error and unwarranted sarcasm than is contained in these words. We are glad that Maine is so shining an exception to the general deplorable conditions herein set forth, and the state is to be congratulated upon its possession of so brilliant an exponent of what agricultural research ought to be. When, however, he writes in this sweeping fashion regarding the conditions surrounding some forty other stations in states covering a continent, many if not most of them some thousand or more miles away, it is not strange that in evolving the material largely from his inner consciousness, he has succeeded admirably in describing what the stations are not.

I write to discuss only a single sentence of this quotation and to resent its import in justice to a constituency not likely to answer for itself in these columns.

Dr. Pearl speaks of "the scientifically uneducated and uncritical farmers" as making up the constituency of the experiment stations and as constituting a real and natural bar to high-grade work. This is a sweeping and serious indictment against a series of federal institutions working in and supported by all the states of the union.

No special superiority is claimed for Illinois, but this occasion is taken to point out that of thirty-five farmers of the state serving on the advisory boards of our experiment station I happen to know of ten who are college graduates representing the following institutions: Dartmouth, Amherst, Yale, Illinois, Iowa and Cornell. How many of the

other members of these boards are college men I do not know, as this information is merely accidental, but they constitute a goodly company. It is the judgment and the criticism of these men that this station must first reckon with, and I have found them entirely competent to judge of the scientific reliability and soundness of our experiments as well as of their practical significance; nor is it necessary to publish sub rosa the better product of our laboratories.

These men are selected not by the station itself, but by the farmers' organizations of the state, and it is fair to assume that as time goes on the men nearest the station and its work will be college trained. In a few days this university will graduate nearly a hundred men from a four years' scientific course in agriculture. By the ratio of the past, fifty-five per cent. of these graduates will go at once to their farms, where, with even a larger number of men who have not fully completed the course and with a still larger number graduated from other colleges, they will constitute a rapidly increasing constituency trained not only in agriculture as a business, but in scientific methods of study. It is this class of men and the colleges which trained them that are in truth covered by what Dr. Pearl denominates as a scientifically uneducated and uncritical constituency.

In this state, and in others so far as my observation goes, since the station started a quarter of a century ago, the uneducated and uncritical farmers simply ignore the station and all it says. They do not count one way or the other in its policy, nor do they constitute or even characterize its constituency.

E. DAVENPORT

UNIVERSITY OF ILLINOIS

DOES A LOW-PROTEIN DIET PRODUCE RACIAL  
INFERIORITY?

TO THE EDITOR OF SCIENCE: The argument usually advanced against the adoption of the "low-protein" diet plan is that the races practising it, when compared with those employing a protein-rich dietary, show in general

some points of physical inferiority or lack energy, aggressiveness or courage. To this it has been replied that the diet is the result, rather than the cause, of such racial characteristics, but by the writers of most books on nutrition and related subjects, both scientific and sensational, this reply has been either overlooked or regarded as inadequate.

As there are no doubt many people who could be benefited by the adoption of a low-protein diet, judging from the results of the studies by Chittenden and others, but who hesitate to try it because of uncertainty as to its possible unfavorable effects, it would seem that the results of new investigations bearing upon the matter should be given wider publicity than their publication in the technical journals usually affords. Accordingly, the present note is offered to call attention to recent work which apparently tends to weaken the above argument in the cases of two of the countries often used as examples of its application, namely, Japan and India.

The disease called beri-beri, a multiple inflammation of the nerves, which is prevalent in most oriental countries, though also known among the fishermen of Newfoundland and Labrador, but which has been most extensively studied in Japan, long baffling explanation, has frequently been brought forward as evidence of the insufficiency of the low-protein diet. The cause of the disease has now been discovered, and found to have no relation to the deficiency of the diet in proteins in the usual sense. For some time it had been known that the use of unbulled grains instead of those from which the bran was completely removed would prevent the disease, and further, that the bran itself contained some principle which would cure many cases that had not progressed too far, but these facts, based chiefly on experiments on animals, were discounted by those who wished to uphold the protein theory.

Finally, however, three Japanese investigators<sup>1</sup> have succeeded in isolating from rice

<sup>1</sup> Suzuki, Shamimura and Odake, *Biochemische Zeitschrift*, XLIII, 89.

bran a nitrogenous base, which they call *oryzanine*, which proves to be a specific for the cure of the disease. Pigeons, chickens, mice and dogs, which would die in a few days or weeks with symptoms of starvation and nerve inflammation if fed on polished rice alone, remained in health when small amounts of oryzanine were added to the diet, as little as 0.3 gram per day being required for an average-sized dog. The bran of other grains and most vegetables were found to contain oryzanine, or at least a substance with similar therapeutic action, while milk, eggs, fish and meat showed little or none, although the alcoholic extract of fresh meat had some beneficial effects on dogs. The authors state that the experience of the Japanese in regulating the dietary of their navy, for instance, confirms in every way the results of these studies, in that beri-beri was stamped out only when foods rich in oryzanine were introduced, and feel justified in concluding that this substance is an absolute necessity for the maintenance of the health, not only of the lower animals, but also of the human race.

Many inferences might be drawn from these results. They show, for instance, the reason why graham bread is more desirable than white, which has been urged by diet reformers for many years, yet has been repeatedly questioned by scientists because no definite reason could be given and because actual experiment showed the white flour product to possess the greater digestibility. They suggest, indeed, that certain nervous troubles, which afflict the civilized races in general and the United States in particular, may have as at least a contributing cause the extensive use of grains from which the bran has been removed. But most interesting of all they show that the apparent inferior power of the Japanese and other eastern races to resist such diseases as beri-beri has nothing whatever to do with their low-protein diet as such, but is caused by their following the dictates of fashion and making use of bran-free, polished rice, as their staple article of diet.

The evident inferiority of the races inhabit-

ing India, which enables a mere handful of British soldiers to keep them under control, is very often referred to as evidence of the inadequacy of the vegetarian—essentially low-protein—dietary made use of by these peoples, as a matter of religious observance. The recent survey by the Rockefeller Sanitary Commission has shown, however, that from 60 to 80 per cent. of the inhabitants of that country are infected with the hookworm. And as the degenerating influence of this parasite on both the physical and intellectual development of its victims is now so well known that further discussion of it is unnecessary, it would appear that we have herein sufficient explanation of the status of these races, without being obliged to assume that their diet is faulty.

With two of the supposedly most typical illustrations of the unfavorable results of a deficiency of protein in the dietary thus explained away, we are surely justified in inquiring, is there any evidence whatever that a low-protein diet ever causes or aids in the production of racial inferiority?

#### A RULING THAT IS AGAINST THE RULES

In the "Opinions rendered by the International Commission on zoological nomenclature"<sup>1</sup> *Opinion 11* (p. 17) reads as follows:

The "Table des genres avec l'indication de l'espèce qui leur sert de type" in Latreille's (1810) "considérations générales," should be accepted as designation of types of the genera in question (Art. 30).

The matter concerns the meaning of the word *type*, as used by Latreille. Some authors hold that Latreille could not have used it in the modern sense of *genotype*, simply because that particular meaning was entirely unknown at this time. This view surely is supported by common sense.

But admitting that there was cause for con-

<sup>1</sup> Smithsonian Inst. Publ. 1938, July, 1910.

tention, and that the case was not fully covered by the regular international rules on nomenclature, it is clear that it might be settled in one of two ways: either by making a special ruling with regard to it, or by inserting a paragraph in the general set of rules, which would cover it.

Both ways have been used: the first is the ruling given in opinion 11; the other is the second paragraph in Art. 30, II. (g), in the "International Rules of Zoological Nomenclature," as published in the Proceedings of the Seventh International Zoological Congress, 1912, p. 46. This says:

The meaning of the expression "select the type" is to be rigidly construed. Mention of a species as an illustration or example of a genus does not constitute a selection of a type.

Every one familiar with the case knows that this paragraph was added to the rules with the special purpose of disposing of the doubt as to the meaning of Latreille's word *type*. At any rate, I know of no other case where it might be applied.

The two decisions are contrary to each other. The ruling made in opinion 11 accepts Latreille's "types" as genotypes in the modern sense. The paragraph under Art. 30, quoted above, forbids it to accept them as genotypes. For there is not the slightest question that Latreille meant the word *type* in the sense of illustration or example, for the other sense did not exist at that time. The argument (opinion 11, p. 18) that the use of the definite article (*l'espèce*) indicates that it was meant in the latter sense, is simply preposterous, since by substituting "une espèce" for "*l'espèce*" the sense of the sentence would not be changed at all.

It is much to be regretted that such an absurd situation has been created. Of course, this might be excused, since the opinion 11 was published two years ahead (in 1910), while the amendment to Art. 30 of the rules did not appear in print till 1912. Yet it might have been expected, for obvious reasons, that the latter should have been known to all members of the International Commission on nomenclature as early as 1907.

Of course the paragraph of the regular rules should prevail. But in order to remove all doubt in the minds of zoologists not familiar with the facts, and in order to avoid that the rulings of the commission might become a farce, one of the next "opinions" to be published should reverse opinion 11. But whether it is expressly repealed or not, opinion 11 can not stand any more, and zoologists not conforming to it should not be criticized for it.

CARNEGIE MUSEUM,  
PITTSBURGH, PA.

#### SCIENTIFIC BOOKS

*The Omaha Tribe.* By ALICE C. FLETCHER, holder of the Thaw fellowship, Peabody Museum, Harvard University, and FRANCIS LA FLESCHÉ, a member of the Omaha tribe. Twenty-seventh Annual Report of the Bureau of American Ethnology, 1905-06. Washington, Government Printing Office. 1911. Pp. 672, plates 65, Figs. 132.

The most obvious thing about this monograph is the authors' well-nigh complete neglect of the work of their predecessors. It is their avowed purpose (p. 30) to borrow nothing from other observers and to present "only original material gathered directly from the native people." Apart from any considerations of historical justice, this principle is unjustifiable from the standpoint of the student. A work so ambitious will naturally be regarded by almost every reader as definitive, as embodying everything that is known concerning the ancient life of the Omaha and as taking cognizance of all additional and contradictory testimony. In both hopes he will be disappointed. There are subjects on which other observers have collected information not furnished by Miss Fletcher and Mr. La Flesché. The parent-in-law taboo, for instance, is treated more fully in Say's notes<sup>1</sup> and in J. O. Dorsey's classical work<sup>2</sup> than in the brief

<sup>1</sup>In James's "Account of an Expedition from Pittsburgh to the Rocky Mountains" (London, 1823), I., pp. 232-234.

<sup>2</sup>"Omaha Sociology," Third Ann. Rept. Bur. Eth., pp. 262-263.

paragraph of the volume before us (p. 335). Say, indeed, furnishes admirably illustrative concrete data. Why should these be withheld from the reader? Even where no additional information is given by an older writer, it is often very important to know the earliest time at which the mere existence of some custom has been recorded. This is especially true of the Plains area where so much diffusion has demonstrably occurred. Yet the authors feel at liberty to ignore the fact that the office of "crow"-wearing policemen for the buffalo hunt was noted by Say<sup>3</sup> as early as 1820. Again, few subjects have aroused more interest among American ethnologists than age-societies and military organizations. J. O. Dorsey's data<sup>4</sup> on these are meager enough, but the authors have practically not a word on either.

The neglect of contradictory evidence gathered by others constitutes a still more serious defect, because the unwary reader thus obtains a one-sided, unduly simplified picture of the condition of affairs. According to Miss Fletcher and Mr. La Flesche, the Black Shoulder gens had two subgentes, one of which was still further subdivided. We get no suggestion that there was any conflict of opinion among their informants or that any change may have occurred in relatively recent times. Additional names, however, are given by J. O. Dorsey,<sup>5</sup> who carefully recounts the contradictory statements of his native authorities and hints at recent changes in the subgentes. With reference to two gentes the authors state that lesser groups within these units "have been mistaken for subgentes" (pp. 172, 178). Had notice been taken of J. O. Dorsey's data, it would be possible to understand what may be meant by these words. As it is, we may assume with some plausibility that the phrase is a covert criticism of J. O. Dorsey, for that writer undoubtedly does speak of "subgentes" where his successors find only "groups." However, a reference to

Dorsey's text<sup>6</sup> and to the authors' definition of a "subgens" reduces the criticism to a verbal misunderstanding. Miss Fletcher and Mr. La Flesche (p. 137) understand by "subgens" a section of the gens that has a distinctive rite, while a "subdivision" or "group" has none, though it had a particular office in the rite belonging to the gens. Dorsey does not understand by "subgens" anything of the kind. He tells us that in his opinion two of his main informants always mean a classification for marriage purposes when they speak of divisions of a gens, and it is clear that this feature is uppermost in his own mind whenever he uses the term "subgens." If the authors' criticism is meant as an innuendo against Dorsey, it is not only disingenuous but incorrect.

It is very interesting to examine the solitary instance of open criticism directed by the authors against their great predecessor. They write (p. 589, footnote):

The statement has been made (11th Ann. Rep. Bur. Ethnol., 542), "In two of the buffalo gentes of the Omaha (the Iñke-sabē and Hañga) there is a belief that the spirits of deceased members of those gentes return to the buffaloes" and the buffalo is spoken of as "the eponymic ancestor." The writer here cited fell into the error of regarding the animal which furnished the peculiar symbol in the rites of these kinship groups as the progenitor of the members of the groups. No such confusion seems to have existed in the Omaha mind. Men were not believed to be descended from animals. If the expressions "Buffalo people," "Elk people," "Deer people" or "Thunder people" were used, these descriptive terms were not employed in a literal sense but as tropes.

A little farther (p. 601) we read a still more categorical denial:

Although, according to the Omaha view, man is so closely connected with the animals, he was not born of them; no trace has been found showing any confusion or mixture of forms; no Omaha believes that his ancestors were elk, or buffalo, or deer, or turtle, any more than that they were the wind, the thunder or the sky.

This criticism, whatever be its merits, is

<sup>3</sup> *Op. cit.*, p. 189.

<sup>4</sup> *Op. cit.*, pp. 342, 352.

<sup>5</sup> *Ibid.*, pp. 230-231.

<sup>6</sup> *Op. cit.*, pp. 242, 245, 258.

dishonest in selecting for its point of departure an incidental statement in a work not specially devoted to the Omaha, instead of taking the fuller accounts in the "Omaha Sociology."<sup>7</sup> In this paper there is given the translation of the words employed in addressing a dying Iñke-sabe, and these words certainly imply a belief that the person addressed is going to rejoin his ancestors, the buffalo. On the same page Dorsey also cites a legend in which the Iñke-sabe are said to have been at one time buffalo. If Dorsey's critics wish to say that he has mistranslated his informant's words, they should so state. If they wish to say that he has sucked his information out of his thumbs, they should so state. If they wish to say that his informants did not represent the consensus of Omaha opinion, they should so state. They should state further that Dorsey himself does not hesitate to tell us that the legend was unknown to two of his best informants. Dorsey was ahead of his generation and of some of the succeeding generation in not suppressing data that might interfere with the smoothness of his tale.

"The Omaha Tribe" must, however, be considered primarily as a field report. Judged from this point of view, it will be found wanting in several respects. In the first place, the tremendous wealth of concrete material is classified according to canons of aboriginal rather than of scientific logic. Thus, the Medicine Pipe ceremony is described under the heading of Music, apparently because its native name means "to sing for some one." Data on agriculture and hunting are assembled with those on the ritual of the maize and the ceremonial hunt. "Social Life" is made to include not only such legitimate topics as kinship terms, courtship and marriage, and etiquette, but also cooking and foods, dressing and tanning skins, quill work, weaving, personal adornment and clothing.

Secondly, there are large fields of ethnological interest that the authors either do not touch at all or treat in a very unsatisfactory manner. Foremost among these is mythology and folklore. Inconsistent as such a supposi-

tion is with the authors' general attitude, we are tempted to assume that their failure to enter into these subjects is an expression of their admiration for the thoroughness with which J. O. Dorsey has accomplished the task that was to be done in this field.<sup>8</sup> Unfortunately the reader does not profit by this exhibition of tacit generosity. For all he could learn from Miss Fletcher and Mr. La Flesche, there has never been published any systematic collection of Omaha tales. Moreover, the fact that a splendid collection exists does not absolve monographers of a tribe from the duty of briefly characterizing the native mythology with reference to both substance and form and of showing its relations to other mythologies. The few paragraphs devoted to this matter in the volume before us (pp. 600, 601, 608) can not be regarded as even a serious attempt in this direction.

Another very remarkable deficiency appears in the discussion of material culture and art. The fact that these subjects are treated with disproportionate brevity is a venial fault, for there are few monographs in which all phases of culture are treated with uniform thoroughness, and some allowances must be made for individual interests. But every professional ethnologist may reasonably be expected to pay some attention to points that have come to be of theoretical interest to his fellow-students. Many questions of this sort relating to the material culture of the Plains Indians have been indicated by Dr. Wissler,<sup>9</sup> but very few of them are elucidated by the authors. We do not learn anything of the form of the travois mentioned on page 275; the description of the cradle-board (p. 327) is too vague for comparative purposes; no opinion is expressed as to the antiquity of the men's shirt among the Omaha (p. 355). As the distribution of painted and embroidered patterns has been diligently studied among the Plains Indians for at least ten years, and as Kroeber

<sup>7</sup>"The Cegiha Language," Contributions to North American Ethnology, Vol. VI.

<sup>8</sup>"Material Culture of the Blackfoot Indians," Anthropol. Papers Amer. Mus. Nat. Hist., Vol. V., Pt. 1.

<sup>9</sup>L. c., pp. 229, 233.

and Wissler have attempted to characterize the art of several Plains tribes, the failure of the authors to furnish the data necessary for classifying the Omaha with reference to their decorative designs is even more surprising.

The subjects that have particularly appealed to the authors are sociology and ceremonial life. The chapter on Tribal Government constitutes a real contribution, giving a clear outline of the several grades of chiefs, the council of seven chiefs and the modes of election. The discussion of the Sacred Pole is also a creditable performance, though it adds rather details than anything fundamental to our previous knowledge. The analogies pointed out by J. O. Dorsey between the Hedewatci and the Sun Dance stand confirmed by the new evidence (p. 253). Unfortunately, in these chapters, as elsewhere, there appears the tendency, now definitely abandoned by ethnologists, of attaching historical value to the origin accounts of a primitive tribe, in spite of their naïvely rationalistic psychology. Though the authors seem to regard the establishment of the chiefs' council as "a development of earlier forms rather than an invention or arbitrary arrangement of the 'old men'" (p. 207), other passages clearly reveal the antiquated view just criticized. In the section on Tribal Organization (p. 134 ff.) we are actually asked to believe that the dual division of Omaha society was but the reflection of a mythological conception! This whole section adds very little to our comprehension of the subject. The specific marriage-regulating functions of the subgentes, touched upon but not clearly expounded by Dorsey, remain unilluminated. What is more important, the authors have not logically correlated their own data. We are told that the gens was exogamous (pp. 195, 325); that the subgens or subdivision of a gens was exogamous (p. 137); that there was a tradition as to the exogamous character of the two grand divisions and that "of the marriages in existence among the Omaha twenty-five years ago, a good majority represented the union between members of gentes belonging to the two rather than to one of these grand divisions" (p. 135). Do not

the authors recognize the fact that if a gens is exogamous, any smaller group within the gens *must* be exogamous; that if an association of five gentes is exogamous, any one of the gentes *must* be exogamous? The problem is to determine which social group is primarily, and which derivatively, exogamous. This it may not be possible to do at present, but it is at least desirable that professional ethnologists should see the problem.

The terms of relationship (pp. 315-17) are not presented in a satisfactory way, though it is true that the subject is an exceedingly difficult one. Here, where the entire psychological interest lies in the native point of view, the authors take for their starting-point the *English* classification of kin. The consequence is great clumsiness of arrangement and useless repetition of terms. Moreover, some interesting meanings of native terms given by Say are omitted in the present list.

By far the most valuable addition to our knowledge is to be found in the chapter on Societies (pp. 459-581), of which two classes are distinguished—the social and the secret societies. The former include the Hethushka (Grass Dance) organization, membership in which was dependent on the reception of public war honors. Our attention is called to the fact that, while the dance has spread over a wide area, only the Omaha observe the religious rites of the opening ceremony. Another (chiefs') society is said to have been the only one "in which headgear that approximated the character of a mask was used" (p. 481). It would be interesting to know whether these headgears resembled those worn by two officers of the Mandan Bull society,<sup>10</sup> in which the face was covered and eyeslits were provided. According to Dorsey,<sup>11</sup> mere buffalo-skin caps, with the horns standing up and the buffalo hair hanging down below the wearer's chest, were worn by four members of another Omaha organization, the Buffalo Dancers. It is curious that in mentioning the Tokalo (Tukala) performance neither Miss Fletcher

<sup>10</sup> Maximilian Prinz zu Wied, "Reise in das innere Nord-America," II., p. 142.

<sup>11</sup> *Op. cit.*, p. 348.

nor Dorsey should have recognized the name as the Dakota term for "fox" or "kit-fox."

Most of the secret societies were entered by virtue of a dream or vision, those having received a revelation from some particular supernatural power being united in the same organization. This does not, however, apply to the Shell society, into which persons were admitted by unanimous consent of the members. All the offices in the last-mentioned society were obtained by purchase; in the other organizations this element, which plays so important a part among several of the Plains tribes, does not seem to be pronounced. Societies composed exclusively of women have not been found among the Omaha (p. 459), but women were evidently prominent in the Shell society, and tradition states that in early times its principal leader was a woman (p. 516). The Shell and the Pebble societies perform shamanistic practises, of which a "shooting" ceremony common to both recalls the Midewiwin of the Central Algonkian, and the authors incline to the opinion that the two societies are historically related. From the fact that the Pebble rituals deal with "more fundamental conceptions" than the origin myth of the Shell society they infer that, granting the relationship, the Pebble society is the older of the two (p. 529). Indeed, there is evidence that at least one of the elements of the Shell performance, the use of a swan wing, has been borrowed from the Pebble society (p. 519); and the description of the "shell" as a round stone in one of the ritualistic songs (p. 529) is interpreted by the authors as pointing in the same direction. Nevertheless, it is quite possible for one society to have borrowed special features from another without being necessarily of later origin in the totality of its traits. As for the relatively more fundamental character of the Pebble society, the authors do not explain what may be their criterion of greater antiquity or primitiveness. One thing is clear: the comparison of the ritual of one organization with the origin myth of another is unjustifiable, though consistent with the authors' belief that the Shell society was founded upon the myth accounting

for its origin (p. 516). Such a view has become less and less tenable as proof has accumulated in different areas that ritual is primary and ritualistic myth secondary.

While the evidence for the greater antiquity of the Pebble society is thus inconclusive, the authors' opinion on the historical connection between the Pebble and Shell organizations seems to me correct. It has been challenged by Radin,<sup>1</sup> but apparently on the basis of a single loose and misleading statement by the authors, viz.,

As these two societies are the only ones in the tribe which observe shamanistic practises and as they both strongly emphasize magic, it is not impossible that at one time they may have been connected (p. 581).

Radin quite properly objects that the observance of shamanistic tricks is too general a phenomenon to warrant the conclusion and that it is unnecessary to assume any historical connection "unless this has been shown to be the case." The authors certainly should have defined what they meant by "shamanistic," but it seems clear that they do not use the term in the accepted sense but with some specific connotation. For to nearly every one of their secret societies they ascribe what others might call "shamanistic practises," yet these are said to be confined to the two societies under discussion. The authors have obviously arrived at their view because common to both societies are several specific features, such as organization by lodges and the shooting ceremony. These features are not found in the Bear and Buffalo and Ghost societies; they are, therefore, not generally phenomena of Omaha life, and their double occurrence is not explained as a mere reflection of Omaha modes of thought. Whatever may be the origin of other elements of the two ceremonial complexes, the traits mentioned have had, in all probability, a common origin.

The foregoing paragraphs have pointed out with sufficient clearness the character of Miss Fletcher and Mr. La Flesche's book. The authors' "The Ritual of the Winnebago Medicine Dance," *Journal of American Folk-Lore*, XXIV. (1911), p. 191.

thors have placed us under obligation by adding a considerable number of facts to our knowledge of the Omaha, notably on the subject of societies. They have not accomplished the task of giving us a definitive study of Omaha ethnology. We feel grateful for the new data presented by them, but we are also very grateful for the fact that they have had for their predecessor so sane, conscientious and competent an ethnographer as the late Rev. J. O. Dorsey.

AMERICAN MUSEUM OF NATURAL HISTORY

### BOTANICAL NOTES

#### NOTES ON RECENT BOOKS AND PAMPHLETS

GEORGE F. ZIMMER'S "Popular Dictionary of Botanical Names and Terms" (Dutton) is intended mainly for botanists, horticulturists and others who have to deal much with plant names. The little book of 122 pages is a little different from the usual type of botanical dictionaries, more attention being given to the meanings of specific names, and this will commend it to many students who are somewhat deficient in their knowledge of Latin. For those it would have been well to have at least indicated the accent for each name.

The little books brought out by Dr. Gustav Lindau, of Berlin, under the general title of "Kryptogamenflora für Anfänger" promise to furnish models which might well be followed by American makers of similar books. Already three books have appeared, namely: "Die höheren Pilze"; "Die mikroskopischen Pilze"; and "Die Laubmoose." Bound in substantial cloth, and containing about 250 pages, these books commend themselves to us as admirably adapted for their purpose—namely, that of helping beginners in the systematic botany of the lower plants.

Bergen and Caldwell's "Practical Botany" (Ginn) aims to relate the study of plants in the secondary schools to everyday life more "than is usually done." Accordingly the book is distinctly of the informational rather than the scientific type, and for this reason will appeal to many principals and boards of educa-

tion. The present reviewer is not in sympathy with the notion that science must always be related to "everyday life" (whatever that may imply), but he finds much to commend in the book. The authors know the science, and pedagogics so well that they have made a useful book, whose faults are due to the underlying theory rather than to any shortcomings on their part. This theory is accountable for the chapters on Timber, Forestry, Plant Breeding, Plant Industries, Weeds, which contain much that is certainly interesting, but that is just as certainly *not botany*. It would be much better for the botanists to allow these applications and extensions of botany to be taken up by foresters, agronomists, horticulturists, agriculturists, etc., a task for which they are entirely competent. We should respect the boundary lines between a science and its applications.

Winkler's "Botanisches Hilfsbuch" (Hinsdorff) gives interesting data regarding about twelve hundred plants (mainly tropical) that have economic value. Although primarily designed for tropical planters, merchants, officials and explorers, it will be found to be a useful book in every botanical library.

The Dudley Memorial Volume published by Stanford University contains papers, appreciations and contributions in memory of the late Professor William R. Dudley who died June 4, 1911. In addition to the memorial addresses and papers and lists of Professor Dudley's pupils (covering 32 pages), the volume includes eight scientific papers. The first of these—"The Vitality of the *Sequoia gigantea*"—was prepared by Professor Dudley himself. The others are "The Morphology and Systematic Position of *Calycularia radiculosa*," by D. H. Campbell; "Studies of Irritability in Plants," by G. J. Peirce; "The Gymnosperms growing on the Grounds of Stanford University," by LeRoy Abrams; "The Synchrony in the Vicinity of Stanford University," by James McMurphy; "The Law of Geminate Species," by D. S. Jordan; "Some Relations between Salt Plants and Salt Spots," by W. A. Cannon; "North American

Species of the Genus *Amygdalus*," by W. F. Wight. The volume constitutes a fitting tribute to the botanist whose life it commemorates.

Burman's "Flora of Manitoba," which was printed two years ago, contains in a small 30-page pamphlet a general discussion of the vegetation of the province of Manitoba followed by a list of the species of flowering plants and ferns. It is the only available guide to the plants of that part of Canada.

Stone's "List of Plants Growing without Cultivation in Franklin, Hampshire and Hampden Counties, Massachusetts" (1913), reminds one of the previous classical lists by Hitchcock and Tuckerman which appeared many years ago under similar titles, and dealing with the flora of the Connecticut Valley. It contains 1,493 species of ferns and flowering plants, 1,190 of which are native, the remaining 303 being naturalized.

Meier's "School and Home Gardens," while dealing with plants, is not botanical, though of interest to many botanists. It is designed primarily to help in the commendable effort to interest children in the planting of seeds and the growing of such plants as may be grown in the windows of school buildings or out of doors, under ordinary care. It can be commended most heartily.

Allied to the last is E. Benjamin Andrews's "The Call of the Land" (Judd) dealing largely with out-of-doors, and the things that grow there. While not botanical, it breathes of flowers, and grasses and growing crops, and of the shrubs and trees that make for comfort and beauty and happiness. It is a book distinctly worth while.

A recent number of the *Missouri Botanical Garden Bulletin* includes descriptions of the laboratories in the garden, accompanied by four half-tone plates from photographs. Accompanying the descriptions is a general discussion containing many suggestive sentences, as "Botanical laboratories are the workshops of those who study plants scientifically." "It is to be remembered that the important botanical gardens of the world are educational institutions." "In the broadest sense these

laboratories must represent the possibility of using apparatus and chemicals, books and herbarium specimens, live material from garden or field, and cultures of microscopic organisms."

A recent circular (113) of the Bureau of Plant Industry contains a suggestive paper on soil bacteriology, by K. F. Kellerman, in which he shows that it is "a subject of almost bewildering complexity, but very intimately associated with the normal physiology of all crop plants." In a later circular (120) the same author has a short paper on nodule-forming bacteria (*Bacillus radicolica*) which should be helpful to those attempting to inoculate the soil with these organisms.

Recent numbers of the *Botanical Magazine* (Tokyo) contain Makino's "Observations on the Flora of Japan," Matsuda's "List of Plants Collected in Hang-chou" (both in English), and Koidzuma's "Morphology, Systematik and Phytogeography of Cupuliferae" (in Japanese), with other shorter articles.

CHARLES E. BESSEY

THE UNIVERSITY OF NEBRASKA

### SPECIAL ARTICLES

#### PRELIMINARY NOTE ON THE RELATIVE PREVALENCE OF PYCNOSPORES AND ASCOSPORES OF THE CHESTNUT-BLIGHT FUNGUS DURING THE WINTER<sup>1</sup>

In studying the dissemination of the chestnut-blight fungus during the past winter the writers obtained some results that showed that, contrary to the generally accepted opinion, pycnospores are produced in enormous numbers and washed down the diseased trees during every winter rain.

The production of pycnospores was tested by what we have termed pycnospore traps. A part of the rainwater flowing over a canker was conducted down a glass slide and through a mass of absorbent cotton. After each rain the cotton of the traps was brought to the laboratory and a quantitative determination

<sup>1</sup>Investigations conducted in cooperation with Office of Forest Pathology, U. S. Department of Agriculture.

made of the number of viable spores of the blight fungus which were retained by each trap. Traps were set at six different locations at West Chester, Pa., and analyses have been made after each rain period for the months of January to April, inclusive.

There were seven rain periods in January with precipitation varying from 0.13 to 0.88 inch. The number of viable pycnosporos obtained from each trap varied from 55,000 to 61,255,000 for each analysis. During February there were four rain periods with precipitation varying from 0.07 to 0.78 inch. After each rain the number of viable pycnosporos obtained from each trap varied from a few thousand to 92,000,000. Similar results have been obtained for the months of March and April.

The cotton for the traps was transported to the laboratory in sterile Petri dishes and the number of viable spores determined by the poured plate method, using 3 per cent. dextrose agar, plus 10.

One of the noteworthy facts is that ascospores do not appear to be washed down the tree during the winter rains, although they are present in abundance in the pustules. That all the colonies appearing in the poured plates made from the cotton traps came from pycnosporos was demonstrated in two different ways: first, by their time of appearance; second, by the absence of ascospores in the centrifuged sediment as determined by microscopic examination.

The effectiveness of the cotton traps in retaining the spores washed down has also been determined by cultures. In many cases only about two per cent. of the spores passing into the cotton was retained. This being true, the figures given above are but a meager expression of the enormous numbers of pycnosporos produced. Considering the fact that we have also demonstrated that pycnosporos can be subjected to freezing temperatures for considerable periods without losing their vitality, they must play a very important part in the dissemination of the blight fungus.

The forcible expulsion of the ascospores of the blight fungus has been reported by Ran-

kin<sup>2</sup> and Anderson<sup>3</sup> and the influence of moisture upon this phenomenon has been demonstrated by both writers. They have not, however, taken temperature conditions into account. The expulsion of ascospores depends not only upon the presence of sufficient moisture, but also upon the temperature to which the lesion has been subjected. The influence of temperature upon the expulsion of ascospores has been determined during the past winter by means of laboratory and field tests. Laboratory tests have shown that bark bearing perithecial pustules, if subjected to low temperatures (42 to 46° F.) for a period would not begin the expulsion of ascospores until exposed to favorable temperatures for three or four days, even though supplied with an abundance of moisture. The minimum temperatures at which spore expulsion takes place vary from 52 to 60° F.

On November 26, 1912, a large number of ascospore traps (49) were placed upon lesions of the blight fungus in a badly diseased copice growth at West Chester, Pa. These have been under continuous observation since that time and accurate rainfall and temperature records kept at that station. There was practically no expulsion of ascospores until March 21, although there had been many rain periods (21) with precipitation varying from 0.01 to 1.64 inch. The above records show that ascospores were not washed down from the lesions during any of the winter rains and that there was practically no expulsion of ascospores during the period from November 26 to March 21.

PENNSYLVANIA CHESTNUT TREE  
BLIGHT COMMISSION LABORATORY,  
PHILADELPHIA, PA.

#### A STRIKING CORRELATION IN THE PEACH

THE importance of correlations in the characters of plants from the standpoint of either research or practise is so well known as to

<sup>2</sup> Rankin, W. H., Report Penna. Chestnut Blight Conference, p. 46, 1912. *Phytopathology*, 3: 73, 1913.

<sup>3</sup> Anderson, P. J., *Phytopathology*, 3: 68, 1913.

need no setting forth. The search for them is one of the imperatives with those who experiment or those who cultivate plants and once begun becomes fascinating—indeed irresistible. The seeker is so seldom rewarded—correlations are not common phenomena—that haste may be pardoned in publishing a discovery.

This spring a most striking correlation in the peach, which seems not to have been noted before, came to the attention of the writer. In the work of describing the flowers of a considerable number of varieties of peaches, Mr. Charles Tubergen, of the horticultural department of this station, found that there was a somewhat remarkable difference in the color of the inside of the calyx cups of different varieties. In some of the blossoms the color of the inner surface of the cup was green, usually a light green but varying somewhat in different varieties. In other varieties the cellular tissue of the inner part of the cup was a deep orange in color—not the surface alone but the tissue to the depth of several layers of cells was orange. In no other part of the calyx, the blossom, or the plant, in the spring of the year, does there appear to be a similar color.

Upon investigation it was found that the flowers having the green cup were those of the white-fleshed varieties while the blossoms with the orange cup were those of the yellow-fleshed ones. We were able to observe the character in two trees each of 307 varieties of peaches and of 47 varieties of nectarines. Of the peaches 145 varieties were white in flesh and green inside the calyx-cup; 162 were yellow in flesh and orange inside the calyx-cup. In the nectarines white and green were correlated in 36 and yellow and orange in 11 varieties.

In neither peach nor nectarine are there intermediates in color of calyx-cup or in flesh of fruit. The parentage of a sufficient number of the varieties examined is known to make it certain that green calyx-cup with white flesh and orange calyx-cup with yellow flesh are each inherited as one in cross-breeds.

What is the explanation of this hidden connection between colors in two organs of the peach which are not only quite distinct but which appear on the plant in periods as widely separated as blooming-time and fruiting-time? The correlations are so constant and their hereditary behavior is such as to suggest that each is a single color character diffused through the flesh of the peach fruit and the inner tissue of the calyx cup. Surely the two organs in which the correlation appears are morphologic units but the capacity to produce the same color, differing probably only in degree in the parts in which it is found, and at widely different times, must be conceived to be a physiologic unit. If so, why localized in these two organs and not generalized throughout similar tissue in other parts of the plant as correlated colors generally are?

This correlation has some practical value in peach-breeding, since it will often enable the breeder to tell a year or two sooner than he otherwise could what color of flesh his peach will have since the first blossoms seldom set fruit; it is of material value in classifying peaches—adding another very constant taxonomic character; through its uses for the breeder and the systematist it becomes ultimately of considerable value to peach-growers. Lastly, it seems to the writer to have value in throwing light on current conceptions of morphologic and physiologic units in plants and also presents a problem to be explained as to why there is a localization of a particular color in two quite distinct organs.

#### MICHIGAN ACADEMY OF SCIENCE

THE Michigan Academy of Science held its nineteenth annual meeting at Ann Arbor on April 2, 3 and 4.

The following is the program as given at the meeting. The numbers marked with a star will be published in the Fifteenth Annual Report of the Michigan Academy of Science.

\*"The Porcupine Gold Deposits of Ontario,"  
Mr. R. E. Hore.

## SECTION OF SANITARY AND MEDICAL SCIENCE

*Thursday, April 3*

\*"Ferments," Dr. J. G. Cumming.

\*"A Bacterial Disease of the Larva of the June Bug (*Lachnosterna* sp.)," Miss Zae Northrup.

"Duration of Tr. Gambiense Infection in Rats and Guinea-pigs," J. F. Morgan.

\*"The Environment of Soil Bacteria," Dr. F. H. Hesselink van Suchtelen.

\*"The Influence of *Bacterium Lactis Acid*i on the Changes caused in Milk by some of the Common Milk Microorganisms," C. W. Brown.

"The Use of Chlorinated Lime for the Disinfection of Drinking Water," Dr. M. L. Holm and E. R. Chambers.

\*"Ozone as a Means of Water Purification," R. W. Pryer.

"Toxic Bases in the Urine of Parathyroidectomized Dogs," W. F. Koch.

"Serum Tests in the Diagnosis of Infectious Abortion of Cattle," Dr. E. T. Hallman.

"The Increase of Hog Cholera Virus by Intraperitoneal Injections of Salt Solution," W. S. Robbins.

"Studies in Avian Tuberculosis," L. R. Himelberger.

"The Sensitizing Group in the Protein Molecule," Dr. V. C. Vaughan.

"Immunization against Tr. Brucei with Cultures," Dr. F. G. Novy.

"Determination of Minimum Lethal Dose of Tr. Brucei," C. A. Behrens.

"Cultivation of Spirilla," P. H. de Kruif.

\*"Secret Remedies, Nostrums and Fakes," Dr. W. S. Hubbard.

## SECTION OF ECONOMICS

*Thursday and Friday, April 3 and 4*

"The London Dock Strike of 1912," Carl E. Parry, of the University of Michigan. Discussion opened by W. H. Hamilton, of the University of Michigan.

\*"Farm Organization as a Factor in Rural Economics," Wilbur O. Hedrick, of Michigan Agricultural College. Discussion opened by Edward D. Jones, of the University of Michigan.

"The Sphere of Pecuniary Valuation," C. H. Cooley, of the University of Michigan. Discussion opened by Frank T. Carlton, of Albion College.

\*"Psychological Antithesis of Socialism," H. A. Miller, of Olivet College.

## GENERAL PROGRAM

Presidential address, by Professor E. C. Case: "The Geological History of Michigan."

Reports on the work of the Michigan Geological and Biological Survey, by R. C. Allen, director, and A. G. Ruthven, chief naturalist.

*Papers on Eugenics*

"Eugenics," Professor Victor C. Vaughan, department of medicine, University of Michigan.

"The Biological Aspect of Eugenics," Professor A. Franklin Shull, department of zoology, University of Michigan.

Public address, "Travels in Mexico," by Professor Charles J. Chamberlain, department of botany, University of Chicago.

The Research Club of the University of Michigan gave a smoker to the members of the academy in the rooms of the University Club, Memorial Building.

## SECTION OF GEOLOGY AND GEOGRAPHY

*Thursday, April 3*

\*"Origin of Continental Forms, IV.," Dr. Howard B. Baker.

\*"Studies in Structure and Stratigraphy in the Saginaw Valley in Relation to Occurrences of Oil and Gas," Mr. R. A. Smith.

"Climatic Variation in Permian Times as recorded in Red Beds of Texas," Professor E. C. Case.

"The Discovery of Illinoian Till in the Detroit River Region," Professor W. H. Sherzer.

"The History of Lake Erie in Post-Glacial Time," Mr. Frank B. Taylor.

"Further Studies on the Variation of the Angle of the Optic Axes, with Temperature," Professor E. H. Kraus.

"Vanadiferous Pyroxenes from Libby, Montana," Professor W. F. Hunt.

"Some Pro-Glacial Lake Shore Lines of the Bellevue Quadrangle, Ohio," Professor Frank Carney.

"Some Problems in Stratigraphy and Correlation of the Pre-Cambrian Rocks of Michigan," Mr. R. C. Allen.

(a) "Results of Leveling along the Algonquin Beach in the Northern Peninsula in 1912," (b) "Order of Development of Glacial Lakes in the Great Lakes Region," (c) "Centers of Dispersion and Probable Extent of the Kansan and Pre-Kansan Drifts," Mr. Frank Leverett.

"The Chemical Composition of Bornite," Professor E. H. Kraus and Mr. J. P. Goldsberry.

"The Teaching of Economics in the High School." Discussion opened by J. E. Mitchell, of Alma College, and F. M. Taylor, of the University of Michigan.

"The Taxation of Local Public Utilities in Michigan," E. H. Ryder, of Michigan Agricultural College.

"Public Utility Accounting in Michigan," David Friday, of the University of Michigan. Discussion opened by H. C. Adams, of the University of Michigan.

#### SECTION OF ZOOLOGY

Thursday, April 3

"Factors Governing Local Distribution of the Thysanoptera," A. F. Shull.

"Results of the Mershon Expedition to the Charity Islands, Lake Huron Coleoptera," A. W. Andrews.

"Types of Learning in Animals," J. F. Shepard.

"The Lepidoptera of the Douglas Lake Region, Cheboygan County, Michigan," Paul S. Welch.

"Check-list of Michigan Lepidoptera. II. Sphingidae (Hawk Moths)," W. W. Newcomb.

"On the Breeding Habits of the Log Perch," Jacob Reighard.

"A List of the Fish of Douglas Lake, Cheboygan County, Mich., with Notes on their Ecological Relations," Jacob Reighard.

"May the Remains of Adult Lepidoptera be Identified in the Stomach Contents of Birds?" F. C. Gates.

"The Mitochondria," R. W. Hegner.

"The Unione Fauna of the Great Lakes," Bryant Walker.

"Notes on the Genus *Edaphosaurus* Cope," E. C. Case.

"Methods of Preparing Teleost Embryos for Class Use" (demonstrations), B. G. Smith.

"An Adult *Diemyctylus* with Bifurcated Tail," B. G. Smith.

"Notes on the Mollusks of Kalamazoo County, Mich.," Harold Cummins.

"Sarcoptid Mites in the Cat," Harold Cummins.

"The Origin of Continental Forms, III.," Howard Baker.

"An Ecological Study of the Birds of Manchester, Mich.," F. Gaige.

"Notes on Crustacea Recently Acquired by the Museum of Natural History of the University of Michigan," A. S. Pearse.

"Distribution of Multiple Embryos on the Blastoderm," O. C. Glaser.

"Nesting of Our Wild Birds," Jefferson Butler.

"The Factors that Determine the Distribution of *Boleosoma nigrum* in Douglas Lake, Cheboygan County, Mich.," H. V. Heimburger.

"Structure of the Olfactory Organs," E. W. Roberts.

"A Method of Producing Cell-like Structures by Artificial Means," E. W. Roberts.

"Some Notes on Rhizopods from Michigan," E. W. Roberts.

"An Interesting Form of Protozoa," E. W. Roberts.

"Oxygen and Carbonic Acid Contents of Douglas Lake, Cheboygan County, Mich.," D. A. Tucker.

"Some Observations on *Asplanchna amphora*," D. A. Tucker.

"Some Effects of Sunlight on the Starfish," H. M. MacCurdy.

"Some Abnormalities Observed in Proteocephalid Cestodes," G. LaRue.

"Note on a Cestode Found in a Garter Snake," G. LaRue.

"Some Observations on Intestinal Villi," O. M. Cope.

"Some Physiological Changes in the Lamprey Egg after Fertilization," P. Okkelberg.

"A Collection of Fish from Houghton County, Mich.," T. L. Hankinson.

"The Lagoons and Ponds of Douglas Lake, Cheboygan County, Mich.," H. B. Baker.

"The Shiras Expeditions to Whitefish Point, Mich.," (1) "Birds," N. A. Wood. (2) "Mammals," N. A. Wood. (3) "Amphibians and Reptiles," Crystal Thompson and Helen Thompson.

"Notes on the Ornithology of Clay and Palo Alto Counties, Iowa," A. D. Tinker.

"A Check-list of Michigan Mammals," N. A. Wood.

"The Variations in the Number of Vertebrae and Ventral Scutes in the Genus *Cegina*," Crystal Thompson.

"An Artificially Produced Increase in the Proportion of Male Producers in *Hydatina senta*," A. F. Shull.

#### SECTION OF BOTANY

Thursday, April 3

"Biometric Studies in Oaks" (with lantern), Carl Oberlin.

"Biometric Studies in Oaks" (with lantern), J. H. Ehlers.

"The Origin of *Capsella arachnoidea*" (with lantern), Henri Hus.

"The Antitoxic Action of Chloral Hydrate upon Copper Sulphate for Pea Seedlings," R. P. Hibbard.

"Improved Methods for the Quantitative Determination of Dilute Solutions of Electrolytes," R. P. Hibbard.

"Effect of Illumination on the Twining of Plants," F. C. Newcombe.

"Conditions for the Diageotropism of *Asparagus plumosus*," Margaretta Packard.

"A Heterotrophic Mycorrhiza" (with lantern), Walter B. McDougall.

"Some Notes on the Black Knot of Plums," J. A. McClintock.

"Some Further Observations on *Sclerotinia*," J. B. Pollock.

"A Sand-binding Fungus," J. B. Pollock.

"The Relic Dunes of Little Point Sable" (with lantern), W. E. Praeger.

"The Pine Hills at Lowell, Mich." (with lantern), Bert E. Quick.

"Plants observed on Mackinac Island in 1912," C. K. Dodge.

"The Flora of Parkdale Farm, Rochester, Mich.," O. A. Farwell.

"The Early Extent of Prairies in Southern Michigan," H. A. Gleason.

"Notes on a Few Plants from the Vicinity of Ann Arbor," H. A. Gleason.

"Car-window Notes on the Vegetation of the Upper Peninsula," R. M. Harper. Read by H. A. Gleason.

"Permanent Vegetation Quadrats at Douglas Lake," Ada K. Dietz.

"Role of Vegetation of a Mill Pond" (with lantern), F. A. Loew.

"Key to the Species and Varieties of *Solidago*, in Michigan," C. H. Otis.

"An Easy Formula for Obtaining Alcohols of any Strength," Richard de Zeeuw.

"Lipolytic Action in a Rust," G. H. Coons.

"Soft Rot of the Hyacinth," G. H. Coons.

RICHARD DE ZEEUW,  
Secretary

EAST LANSING, MICH.

## SOCIETIES AND ACADEMIES

### THE BOTANICAL SOCIETY OF WASHINGTON

THE eighty-ninth regular meeting of the Botanical Society of Washington was held in Assembly Hall of the Cosmos Club, at 8 P.M., Tuesday, May

6, 1913, with twenty-four members and two guests present.

The following papers were presented:

*The Effect of the Recent Freeze in California* (with lantern): Dr. DAVID GRIFFITHS.

Dr. Griffiths discussed the effect of the January freeze on vegetation of the southwest, with special reference to California. The main regions where tropical and subtropical things are being grown were visited. He showed 40 slides made from negatives taken in February and March, showing injuries to citrus fruits, avocados, cherimoyas, mangoes, carobs, acacias, olives, eucalyptus, etc.

While the temperatures were unusually low, there are indications that they have been lower in the remote past. That such cold spells of weather are very infrequent is proved by the fact that such natives as *Rhus laurina*, *eriogonums* and other natives in California, and the giant *Cereus, cholla, Celtis, Olneya*, etc., in southern Arizona, are severely injured. Many introduced trees which have attained a diameter of three feet have been killed outright.

Injuries were very severe throughout all of the citrus regions, but even where the temperatures went to 10-17° F. in general throughout a region, an occasional orchard situated upon an abrupt elevation above the general plain escaped with even unfrozen fruit. Owing to differences in elevation, air-drainage and exposures, conditions are exceedingly varied and present some of the most important problems in connection with the relation of climatic conditions to crop development. At no time in the present generation has there been such an opportunity to determine the adaptability of the scores of introduced plants of the Pacific Coast region. Through some of the various agencies operating in agricultural lines a careful survey should be made the present season to systematize and place on record the results of a condition which, although of infrequent occurrence, is nevertheless of the utmost scientific and economic import.

*The Method of Types Applied to the Nickernut:*

Mr. H. C. SKEELS.

Mr. Skeels called attention to the last sentence of division (e) under Canon 15 of the American Code of Botanical Nomenclature, which reads as follows: "The genera of Linnæus's Species Plantarum (1753) are to be typified through the citations given in his Genera Plantarum (1754)." Under this clause the following genera were mentioned:

Genus	Type Species	Now Referred to
<i>Alpinia</i>	<i>A. racemosa</i>	<i>Renealmia</i>
<i>Cerbera</i>	<i>C. ahouaj</i>	<i>Thevetia</i>
<i>Cratogeomys</i>	<i>C. aria</i>	<i>Sorbus</i>
<i>Cucurbita</i>	<i>C. lagenaria</i>	<i>Lagenaria</i>
<i>Glycine</i>	<i>G. apios</i>	<i>Apios</i>
<i>Hibiscus</i>	<i>H. malvaviscus</i>	<i>Malvaviscus</i>
<i>Jatropha</i>	<i>J. manihot</i>	<i>Manihot</i>
<i>Medicago</i>	<i>M. radiata</i>	<i>Trigonella</i>

Applying the method of types to the nickernut, Mr. Skeels called attention to Mr. Trimen's identifications of the Flora Zeylanica specimens which are published in Vol. 24 of *The Journal of the Linnean Society, Botany*. On the basis of these identifications, Mr. Skeels concluded as follows:

"In conclusion, going back to our three original species, the 'Catti kitsjil' of the East Indies, the *Casalpinia nuga* (L.) Aiton of the floras, under the method of types of the American Code, becomes *Casalpinia crista* L., the type being Fl. Zeyl. 157. The common gray-seeded nickernut, generally known as *Casalpinia* or *Guilandina bonducella*, becomes *Guilandina bonduc* L., the type being Fl. Zeyl. 156. And the yellow-seeded, large-leafted nickernut, generally known as *Guilandina bonduc*, becomes *Guilandina major* (DC.) Small, being based through De Candolle, on *Guilandina bonduc* L. Species Plantarum, ed. 2."

*What would be the Effect of the Arctic Night on Tropical or Subtropical Vegetation?* Dr. F. H. KNOWLTON.

Dr. Knowlton called attention to the ancient floras of the North Polar region. Many of the fossil plants found there are of a tropical or sub-tropical character. No satisfactory explanation of the relation of such plants to the conditions of light and darkness supposed to have prevailed has been found. Dr. Knowlton asked for suggestions from the members of the society and a brief discussion followed.

C. L. SHEAR,  
Corresponding Secretary

#### PHILOSOPHICAL SOCIETY, UNIVERSITY OF VIRGINIA MATHEMATICAL AND SCIENTIFIC SECTION

THE eighth regular meeting of the session of 1912-13 of the Mathematical and Scientific Section was held May 19.

Professor R. M. Bird read a paper by himself and Mr. W. S. Calcott on "Some Studies of Chemical Reactions, which may be Connected with the Constant Association of Vanadium Sulphide with Sulphur-bearing Petrols and Asphalts."

Mr. Justus M. Cline presented a paper by him-

self and Professor Thos. L. Watson on "The Drainage Changes in the Shenandoah Valley Region in Virginia."

Professor Thos. L. Watson read a paper entitled "A Meteoric Iron from Paulding County, Georgia."

Professor Chas. N. Wunder read a paper on "A Photometric Survey of the Stars of the Hugginsian Region of the Great Nebula of Orion."

Professor W. H. Echols read by title a paper "On the Expansion of a Function in Terms of Rational Functions." This paper will be read at the regular meeting in October.

WM. A. KEPNER,  
Secretary

#### UNIVERSITY OF VIRGINIA

#### SCIENCE CLUB OF THE UNIVERSITY OF WISCONSIN

AT the 125th regular meeting of the club, held April 17, 1913, Dr. A. S. Loevenhart, of the department of pharmacology of the University of Wisconsin, presented a paper on "The Relation of Oxidative Processes in the Central Nervous System to Stimulation and Depression."

The observed effects of asphyxia are, in the order of occurrence, stimulation, depression, paralysis, death. By using carbon monoxide, hydrocyanic acid and other drugs that inhibit the oxygen-carrying power of the blood without interfering with the elimination of carbon dioxide, and by reducing the time of the experiment so much that no accumulation of acid products is possible, it is found that decrease of oxidation *per se* is responsible for the initial stimulation observed in asphyxia.

Increased oxidation, secured by the use of certain derivatives of iodo-benzoic acid, results in suspension of respiration and other evidences of depression of the central nervous system.

Anesthesia is a case of secondary depression resulting from decreased oxidation as opposed to depression from increased oxidation, which is probably the condition occurring in sleep. A "safe" anesthetic is therefore an impossibility, since the function of an anesthetic is to hold bodily oxidation down in the region of depression between stimulation and death.

The lecture was illustrated with a number of diagrams from automatic recording apparatus, and some pieces of apparatus that had been specially designed or improved in connection with the investigation.

ERIC R. MILLER,  
Secretary

NEW SERIES  
VOL. XXXVII. No. 964

FRIDAY, JUNE 20, 1913

SINGLE COPIES, 15 CTS.  
ANNUAL SUBSCRIPTION, \$5.00

## THE GRAMERCY-PRECISION BALANCES

*Made Entire of Magnalium      For Students' Use and Technical Purposes*

The unsightly appearance of ordinary students' balances, with wooden base and lacquered metal pillar, beam, pans, etc., after they have been in the laboratory for a short time, subjected to acid and other laboratory fumes, has made the Gramercy Precision Balances meet with immediate favor in educational and industrial laboratories throughout the world.

The balances are made entirely of magnalium, and lacquered with a durable colorless substance. They are light in weight, most durable, and elegant in appearance.

**The prices are very moderate.**

*Descriptive pamphlet on request*

### EIMER & AMEND

*Headquarters for Chemical Apparatus and Chemicals*

**205-211 Third Ave.**

**New York City**

# Important Books in Science

**Morphology of Gymnosperms.** By JOHN M. COULTER, Professor of Botany, and CHARLES J. CHAMBERLAIN, Associate Professor of Botany, in the University of Chicago. 470 pages, 462 illustrations, 8vo, cloth; postpaid, \$4.22.

Each of the seven great groups of gymnosperms is here presented in detail, and a final chapter discusses the problem of phylogeny and points out the evolutionary tendencies. The extinct groups are now included for the first time; and vascular anatomy is recognized as a morphological subject of first importance. The illustrations are numerous and in large part original.

*Nature.* The book is an invaluable record, admirably illustrated, of our present knowledge of the older type of seed-plants.

**Outlines of Geologic History with Especial Reference to North America.** Symposium organized by BAILEY WILLIS, of the United States Geological Survey; compilation edited by ROLLIN D. SALISBURY, Professor of Geographic Geology in the University of Chicago. 316 pages, 8vo, cloth; postpaid, \$1.66.

These essays and discussions embody the present state of knowledge and opinion concerning many of the fundamental problems of North American geology. The value of the book is greatly enhanced by the fifteen paleogeographic maps by Bailey Willis.

*Scottish Geographical Magazine.* The value of such a collection is very great, as each writer discusses only the formation or subject which has formed his own special study.

**American Permian Vertebrates.** By SAMUEL WENDELL WILLISTON, Professor of Paleontology in the University of Chicago. 152 pages, 39 plates, 8vo, cloth; postpaid, \$2.68.

This work comprises a series of monographic studies, with briefer notes and descriptions, of new or little-known amphibians and reptiles from the Permian deposits of Texas and New Mexico. The work is illustrated by the author.

*Athenaeum.* The paleontologist will welcome the work as a solid contribution to our knowledge of a fauna which is of exceptional interest to the student of evolution, inasmuch as it includes forms that help to bridge over some of the differences between reptiles and amphibians.

## STANDARD LABORATORY MANUALS

**Methods in Plant Histology.** With Illustrations. By CHARLES JOSEPH CHAMBERLAIN, Associate Professor of Botany in the University of Chicago. 272 pages, 8vo, cloth; postpaid, \$2.39.

*Education.* It is an excellent book for the individual worker and for classes in colleges.

**Animal Micrology.** By MICHAEL F. GUYER, Professor of Zoology in the University of Cincinnati. 250 pages, 8vo, cloth; postpaid, \$1.88.

*Science.* A concise, eminently practical, and well-classified treatment.

**A Laboratory Guide in Bacteriology.** By PAUL G. HEINEMANN, Instructor in Bacteriology in the University of Chicago. 216 pages, 12mo, cloth; postpaid, \$1.59.

*American Journal of Medical Sciences.* A book such as this must facilitate very greatly the practical class work, for which it is most excellently adapted.

**Neurological Technique.** By IRVING HARDESTY, Professor of Anatomy in Tulane University. 196 pages, 8vo, cloth; postpaid, \$1.87.

*British Medical Journal.* The instructions are thoroughly practical.

**Laboratory Outlines for the Study of the Embryology of the Chick and the Pig.** By FRANK R. LILLIE, Professor of Embryology in the University of Chicago. 48 pages, paper; postpaid, 27 cents.

A valuable contribution toward the establishment of a standard of embryological work for students generally, and for others desiring a convenient guide to the order of study of this subject.

## LIVINGSTONE AS AN EXPLORER<sup>1</sup>

DAVID LIVINGSTONE, it is scarcely necessary to remind you, was of Highland descent, his grandfather having been a crofter on the little island of Ulva, off the west coast of the larger island, Mull. In appearance he showed clearly that the predominant strain in his ancestry was what we call Iberian for want of a more definite word. That is to say, that he was of that very old racial strain still existing in western Scotland, western Ireland, Wales and Cornwall, which has apparently some kinship in origin with the peoples of the Mediterranean, and especially of Spain and Portugal. Indeed, according to such descriptions as we have of him, and such portraits as illustrate his appearance, he was not unlike a Spaniard, especially in youth and early middle age. His height scarcely reached to 5 feet 7 inches, his hair and moustache, until they were whitened with premature old age, were black, his eyes hazel, his complexion much tanned by the African sun, but at all times inclining to sallow. He possessed a natural dignity of aspect, however, which never failed to make the requisite impressions on Africans and Europeans alike. Bubbling over with sly humor, with world-wide sympathies, and entirely free from any narrowness of outlook, he possessed a very strong measure of self-respect, coupled with a quiet, intense obstinacy of purpose.

<sup>1</sup>From the address to commemorate the centenary of the birth of Livingstone given before the Royal Geographical Society, London, and the Royal Scottish Geographical Society and printed in the journals of these societies.

Let us briefly consider his achievements as a geographical discover. He directly inspired the search for Lake Ngami, and was the main agent in carrying South African exploration beyond the arid plateaus of Bechuanaland and the Kalahari desert into what is really the Zambezi basin. Oswell and Murray contributed to the cost of his journeys, but he by his influence found the guides and secured the friendship or the neutrality of the native chiefs. He acted as interpreter-in-chief, and, thanks to the mastery he had acquired over the Sechuana language, was able to converse fully and freely with the natives of South-Central Africa. He also picked up a considerable knowledge of other dialects. He served diligently and skilfully as physician and surgeon all who were connected with these journeys. But his own predilections were for botany, zoology and the study of man. It was the impression that native reports of his character had made on Sebituane, the Makololo conqueror of the upper Zambezi, and the resultant protection afforded, which made it so easy for Livingstone and Oswell to reach the Chobe River and the upper Zambezi in 1851.

Between 1852 and 1856, Livingstone traced the main course of the Zambezi from its confluence with the Chobe northwards to near the sources of the Liba, and from this point westwards he was the first scientific geographer to lay down correctly the position of the upper Kasai and Kwango affluents of the Congo.

Livingstone may be quoted as the discoverer of the great Kasai (perhaps the principal among the Congo affluents for volume and for extent of drainage area). At first it would seem probable that the Pombeiros, at the beginning of the nineteenth century, must have crossed the Kasai in order to reach the court of the Mwata Yanvo. But

they appear to have deflected their route southwards, after leaving the upper Kwango, so that they pass round the sources of the Kasai, leaving them to the north. Ladislaus Magyar, the Hungarian explorer and trader (who married a negress of Bihé and traveled over Angola between 1849 and 1864), penetrated about 1851 to the upper Kwango and the northwest limits of the Zambezi basin, and may have seen the infant Kasai in 1855, a few months before or after Livingstone passed by. But he did not communicate the information to the world until after Livingstone's journey, and never, I think, specifically mentioned the Kasai, at any rate, before the publication of Livingstone's book. Moreover, he was no trained geographer or taker of observations for fixing points of latitude and longitude. Silva Porto, a Portuguese trader of Bihé, reached the upper Zambezi and South Congoland in the fifties and sixties, but his wanderings resulted in no additions to the map of Africa.

It is, indeed, remarkable what Livingstone's predecessors missed rather than what they found. Dr. Lacerda reached to little Lake Mofwe, an isolated lagoon about 20 miles south of Mweru and a short distance east of the Luapula. Yet apparently neither he nor any member of his expedition, before or after his death, had the curiosity to penetrate northwards one day's journey and discover Lake Mweru, or visit the banks of the Luapula. Going through the Bisa country they heard of a lake—"Lake Chua," or Shua, a short distance to the westward, and knew that the Chambezi flowed into it. This was Livingstone's Bangweulu (named, as he tells us, from one of its islands). But the Portuguese of Lacerda's mission, like those of the Monteiro-Gamitto expedition of 1831-32, made no effort to locate Bangwenlu and place it definitely on the map. Lake Nyasa was

heard of (as "Nyanja") by the Portuguese of the eighteenth century and early nineteenth; but it was not till 1846 that its waters—so far as historical records go—were actually seen by a Portuguese (Candido de Costa Cardoso). Gasparo de Bocarro passed near to Lake Nyasa in 1616 on his way to Kilwa and Mombasa, but seems to have crossed Lake Malombe or the upper Shiré only, and not actually to have seen Lake Nyasa.

Returning from Angola to the Chobe River, he discovered the Victoria falls, and followed the Zambezi more or less closely down to its delta, emerging on the sea-coast at Quelimane.

On his second Zambezi expedition he revealed to the world Lake Nyasa, Lake Chilwa (miswritten Shirwa), the high mountains of the Shiré region, and the course of the Shiré River, the Luangwa River to the west of Lake Nyasa, most of the northern confluent of the Zambezi in their lower courses, and the Butonga highlands. This second expedition was also the means of effecting a great increase in our knowledge of the Zambezi delta.

On his third great African journey he renewed previous explorations in the direction of the Ruvuma, and traced a good deal of the course of that East African river. He was practically the first European to explore West Nyasaland and the northern Bemba or Awemba country; he discovered the south end of Tanganyika, and made a shrewd guess at its outlet through the Rukuga (which river he styled the Longumba). He first revealed the great Mweru swamp or Chisera. ["Elephants, buffaloes and zebras grazed in large numbers on the long sloping banks of a river or marsh called Chisera." This considerable extent of alternate swamps or shallow water was afterwards rediscovered by Sir Alfred Sharpe.] Livingstone made known

to us lakes Mweru and Bangweulu and the connecting Luapula River, and the course of the great Lualaba or upper Congo at Nyangwe. He also recorded the existence of the upper Lualaba or Kamolondo. He was the first European to penetrate as far north as S. lat.  $3^{\circ} 30'$  near the Elila River, and describe the Manyema forests with the large chimpanzies and pygmy elephants found in them. He mentions for the first time the Lomami River, and is the first explorer to hear of the country of Katanga, its mineral wealth and its—as yet—unexplored, inhabited caverns of vast size.

A month to the westward of Kazembe's country lies Katanga, where the people smelt copper ore (malachite) into large ingots shaped like the capital letter I, weighing from fifty to a hundred pounds. The natives draw the copper into wire for armlets and leglets. Gold is also found at Katanga.

Livingstone was the first writer to mention the possible existence of Lake Kivu; of Kavirondo gulf (Victoria Nyanza); and of Lake Naivasha: from Arab information, of course.

He was the first to record the existence of drilled stones in the country to the southwest of Tanganyika, which seemed to be evidence of the existence of a people of ancient Bushmen culture in that direction, and his remarks generally on the Stone Age in Africa, on the possible existence of undiscovered ancient types of mammals and of mammalian fossils, all show an enlightenment in speculative scientific imagination greatly in advance of his times. He was also in all probability the first writer since the Portuguese chroniclers of the sixteenth century to allude to the remarkable ruins of stone-built forts, villages and cities in southeast Africa. He derived his information from natives, and perhaps also from Boer hunters. He also mentions the coins found in excavating the shore of

Zanzibar Island, with Kufic inscriptions, and perhaps dating back to the ninth or tenth century A.D. (Sir John Kirk confirms this statement, and adds that some of these coins were of Harun-ar-rashid's reign, and bore the name of his viziers, Yahya or Fadl.)

His biblical studies drew him into Egyptology, and one of his incentives to the exploration of the Nile sources was the conviction that Moses when living in Egypt had taken a great interest in Nile exploration. Livingstone half hoped that in discovering the ultimate sources of the Nile he might come across archeological traces of Egyptian influence. He was not pursuing in this direction an absolute chimera.

The physical appearance of so many of the Bantu tribes between Lunda, on the southwest, and Manyema, Bambare and Buguha, on the northeast, constantly suggested to Livingstone's mind the idea of an immigration of Egyptians into Central Africa. Had he lived to penetrate to the countries north of Tanganyika to see the Hima or Tusi aristocracy on the highlands of equatorial Africa, he would have been still more convinced of the ancient inflow of Egyptian influence into these regions: though it is a theory which it is very unsafe to pursue on the scanty evidence we possess at the present time.

When traveling from Tanganyika to Mweru in 1869, he remarks on the appearance of the chief and people of Itawa.

Nsama, the chief, was an old man with head and face like those sculptured on the Assyrian monuments. . . . His people were particularly handsome, many of the Itawa men with as beautiful heads as one could find in an assembly of Europeans. Their bodies were well shaped, with small hands and feet—none of the West Coast ugliness—no prognathous jaws or lark heels.

There is another entry in his journal derived from Arab information which bears

on this theory of the Hamitic permeation of Negro Africa.

The royal house of Merere of the Basango [northeast Nyasaland] is said to have been founded by a light-colored [Hamitic?] adventurer, who arrived in the country with six companions of the same race. Their descendants for a long time had straight noses, pale skins and long hairs.

His journeys into southern Congoland threw a very interesting light on a native kingdom made famous by the earlier Portuguese explorations—that of the Kazembe of Lunda, whose capital was between lakes Mweru and Bangweulu.

In the early seventeenth century a great negro empire had arisen in southern Congoland, partly due, no doubt, to the arms and trade goods derived from the Portuguese, but partly also to the after-effects of the Sudanese civilization of Central Congoland under the Bushongo dynasty. This empire of Lunda ruled over all the south of Congoland and a small part of northern Zambezia.

In the early eighteenth century a member of the family of the Lunda emperor, or "Mwata Yanvo," moved to the south of Lake Mweru and founded a feudatory kingdom there. He received the title of Kazembe or "lieutenant."

Kazembe's capital was by the side of a little lake called Mofwe. Livingstone approached it along a path as broad as a carriage road one mile long, the chief's residence being enclosed by a wall of reeds 8 or 9 feet high and 300 yards square. The innermost gateway was decorated by about sixty human skulls, and had a cannon, dressed in gaudy colors, placed under a shed before it. This, no doubt, was a gift from the Portuguese. Kazembe himself had a heavy, uninteresting countenance, without beard or whiskers, somewhat of the Chinese type, his eyes with an outward squint. He smiled but once during the day, yet that was pleasant enough, though

the cropped ears of his courtiers and the human skulls at the gate made Livingstone indisposed to look on him with favor. Kazembe was usually attended by his executioner, who wore a broad Lunda sword under his arm, and a scissor-like instrument at his neck for cropping ears. This was the punishment inflicted on all who incurred the Kazembe's displeasure.

Kazembe sat before his hut on a square seat placed on lion and leopard skins.

He was clothed in white Manchester print and a red baize petticoat so as to look like a crinoline put on wrong side foremost. His arms, legs and head were covered with ornaments, and a cap made of various-colored beads in neat patterns. A crown of yellow feathers surmounted his cap. His head men came forward, shaded by a huge ill-made umbrella and followed by dependents. . . .

This Central African monarch (whose descendant was finally deposed for cruelties by the British government) bore an evil reputation; yet he was a good friend to Livingstone and put no obstacle in his path; though he politely told him that lakes and rivers only consisted of water, and that to ascertain this fact by ocular inspection would not repay him for his fatigues and outlay in trade goods!

Livingstone from boyhood had taken a great interest in botany and in the appearance of trees and flowers in the landscape. His observant glance led him to note all the more salient features of the African flora from the Cape to the equatorial forests of Manyema. His books are full of little word-pictures of the strange, stately or beautiful trees and plants he encounters. He records in his journal the spectacle of the *Crinum* "lilies" of the Luangwa valley, which in the first rains "flower so profusely that they almost mask the rich, dark, red color of the loamy soil, and form a covering of pure white where the land has been cleared by the hoe." The weird stone- or pebble-like *Mesembryanthemums*

of the Kalahari Desert, and the gouty, leafless geraniums and vividly colored pumpkins and gourds of the same region arrest his attention; the *Bauhinia* bushes with their golden or bluish tinted, bifid leaves, and the scale insects on them exuding a sweet manna; the noble giraffe-acacia trees, the euphorbias of very diverse modes of growth, the *Strophanthus* creepers whose seeds possess medicinal or violently poisonous qualities, the borassus and hyphæne fan-palms, the wild date, and the "noble raphias," the pandanus and dracaenas of the Zambezi delta or of inner Congoland, the innumerable forest trees of northern Zambesia and southern Congoland: all are illustrated in his pages by well-chosen words and sometimes explanatory drawings; and most are correctly named, in contrast with the very unscientific nomenclature of the generality of travelers in his day.

Livingstone notices as he descends the slopes of the mountains towards the Chambezi the abundance of the fig-tree which yields the bark-cloth, so that the natives cared little for the cotton cloths of Europe and India. He also in this region observed green mushrooms, which, on being peeled, revealed a pink fleshy inside (the *Visimba* of the natives). Only one or two of these mushrooms were put into a wooden mortar to flavor other and much larger kinds, the whole being pounded up into a savory mess, which was then cooked and eaten. But in Livingstone's experience this mushroom diet "only produced dreams of the by-gone days, so that the saliva ran from the mouth in these dreams and wetted the pillow." The country on the Chambezi slope of these Muchinga mountains was devoid of game, the game having been killed out by far-reaching and long-continued drives through the hopo fences into pitfalls.

He crossed Tanganyika to resume his

search for the Lualaba in July, 1869. In his journal he recorded the abundance of pandanus screw pines off the west coast of that lake. As he traveled through the Guha and Manyuema countries he entered "the land of gray parrots with red tails" ["to play with gray parrots was the great amusement of the Manyuema people"]. The Manyuema country he describes as "surprisingly beautiful, palms crowning the highest heights of the mountains, and climbers of cable size in great numbers hanging among the gigantic trees." Strange birds and monkeys were everywhere to be seen. The women went innocently naked; and the Adams of this Eden were nothing but a small piece of bark cloth. Both sexes atoned for their absence of clothing by having their bodies tattooed with full moons, stars, crocodiles, "and devices recalling Egyptian hieroglyphics." Yet although their country—prior to the Arab raids—seemed an earthly paradise, small-pox came every three or four years to Manyumaland and killed many of the people.

It was in the Manyuema country that he came into contact with the large chimpanzi (*Troglodytes schweinfurthi*) of eastern equatorial Africa, whose range extends from the Welle-Mubangi River and Unyoro to the eastern bend of the upper Congo and the west coast of Tanganyika.

The soko, as he called this large chimpanzi, always tried to bite off the ends of the fingers and toes of the men with whom it fought, not otherwise doing them any harm. It made nests, which Livingstone described as poor contrivances with no architectural skill.

The Manyuema told him, however, that the flesh of the soko was delicious; and Livingstone thinks that through devouring this ape they may have been led into cannibalism. The sokos gave tongue like fox-

hounds; this was their nearest approach to speech. They also laughed when in play, and in their relations with the natives were quite as often playful as ill-tempered. The lion, which seemingly existed in the Manyuema country in spite of the forest, was said to attack and kill the soko, but never to eat him. The sokos lived in monogamous communities of about ten. Intruders from other camps were beaten off with fists and loud yells. If one tried to seize the female of another, the remainder of the party united to box and bite him. The male often carried his child, relieving the mother occasionally of her burden.

Rhinoceroses were shot in the Manyuema country. He also alludes to the pygmy elephant of Congoland, "a small variety, only 5 feet 8 inches high at the withers, yet with tusks 6 feet 8 inches in length"; and notes the killing of an elephant with three tusks, one of them growing out through the base of the trunk. [The pygmy elephant (*Elephas africanus pumilus*) of the equatorial Kamerun-Congo forests, was only rediscovered in the early part of the twentieth century.]

Livingstone was almost an expert in geology and petrology. He felt the keenest interest in the records of the rocks, and fully realized the importance of paleobotany. When descending the valley of the Central Zambezi in 1856 he discovered fossil remains of *Araucaria*, or of conifers now confined to South America and Australasia; and fully realized what his discovery meant in regard to ancient land connections between South Africa, India and South America. He was much impressed with the probable coal-bearing strata of sandstone throughout the Ruwuma Valley. A great many pieces or blocks of silicified wood appeared on the surface of the soil at the bottom of the slope up the plateaus. He wrote:

This in Africa is a sure indication of the presence of coal beneath.

In the sands of some of the rivers pieces of coal were quite common. He originated the theory of the rift valley of Lake Nyasa.

It looks as though a sudden rent had been made so as to form the lake and tilt all these rocks nearly over [namely, in the direction of Ruvuma].

His observations would seem to show that the level of Lake Nyasa was once about 55 feet above its present high-water mark. It is possible that at this high level its overflow of waters first of all passed into the basin of Lake Chilwa, and then flowed northwards into the Ruvuma system.

Stanley, by relieving him when he did, gave him at least two more years of life, a certain measure of happiness, and the sweet consolation that he was not forgotten, and that the magnitude of his discoveries was appreciated. In this brief sunset glow of his life he turned his face once more towards Lake Bangweulu in order to trace the course of the Luapula to Mweru, and its junction with the Lualaba, half hoping that he might then travel down the broad stream till he entered the Bahr-al-Ghazal or the Albert Nyanza; but, although he now possessed comforts he had long lacked, and faithful, comparatively disciplined men, his strength gave out under constant exposure to rain, and to soakings in crossing rivers and marshes. Severe hemorrhage set in from the bowels, and he died of exhaustion at Chitambo's village in the swamps near the south shore of Bangweulu on May 1, 1873.

This brief record of his achievements and his sufferings may fitly close with an extract from his last journals, showing that he died a martyr to that form of religion which we call science:

In this journey I have endeavored to follow with unswerving fidelity the line of duty. . . . All the hardship, hunger and toil were met with the full conviction that I was right in persevering to make a complete work of the exploration of the sources of the Nile.

HARRY H. JOHNSTON

#### LECTURE AND RECITATION METHODS IN UNIVERSITY INSTRUCTION

A REFERENCE to the systems of instruction in Germany, Canada and the United States will most readily bring out the relative value of the lecture and recitation methods in university instruction. In the German and many of the Canadian universities the popular method of giving instruction consists in delivering a series of lectures and following these by a rigid final examination, while in the United States the daily recitation of textbook assignments is much more common than in the former countries. In Canada the term lecturer is frequently applied to a regular member of the faculty, but in the United States it is seldom heard except when applied to a temporary member of the university staff, who has been engaged to give a course of lectures on some special subject, and a college professor is more frequently regarded as a teacher than as a lecturer.

A student, therefore, who has been familiar with the German system or who has spent some time in certain departments of the Canadian universities, and then enters almost any of the American institutions of higher learning, will be impressed by the difference in the methods of instruction in these various countries. He has been familiar with the freedom of the lecture system where he is in a large measure placed on his own responsibility and, as a rule, may attend lectures or not as he chooses. Under this system he is inclined to feel that the professor has no concern regarding his success or failure beyond the duty of providing him with the intellectual substance of the lecture course in the best form and exacting a pound of flesh on the final examination. This notion is, as a rule, due to the lack of intimate contact between the in-

structor and the students because lecture classes are frequently very large. It is also often erroneous because the student is surprised to find later how familiar a discerning lecturer has become with his characteristics, from seeing him day after day in the lecture hall.

The fact that the student feels free during the year to follow his own desires, but at the same time knows that the responsibility for his conduct falls upon his own shoulders, has much in its favor for most students, although it is detrimental to some. In the better class of students it develops a certain independence of action and thought which better fits them for the responsibilities they must assume after leaving college, while in the students who are weak morally it often cultivates undesirable habits which lead to excesses. In Germany, where the university students are left almost entirely to themselves during the first two years of their academic life, the results of absence of restraint are expressed in the large amount of social immorality which is said to exist among German students. No doubt this freedom in college life is largely responsible for the conditions which led Bismarck to say that one third of the German students are never heard of, one third "gehen zum Teufel" and the other third rule Germany.

An objection to the lecture-examination system which is frequently raised, is that too much stress is laid on the final examination. It is said that good students often do not do themselves justice because of undue mental and physical strain and that the work is neglected until the last few weeks or months of the term, then crammed up for the final examination and immediately forgotten. It is no doubt true that most students can make a much better showing on daily recitations than when called upon to discuss a whole term's work, but, after all, the test which tries out a man for the larger spheres of his future life, is not that of holding enough matter in his mind to recite one day's assignment, but rather at the end of a term, or year to be able to sum up and round out the whole season's work. The greater benefits derived from a

college course consist not in the abundance of details remembered from the text-books—because that is necessarily small—but rather in the inspiration for achievement and the capacity for work which a man develops by studying under enthusiastic and capable instructors. In preparing for the final examinations, during the last few weeks or months of the year, the student cultivates the ability to do the greatest amount of work in the least possible time, and a man now connected with a large commercial firm in Chicago once remarked to the writer that the best training for his future business career which he ever received was in preparing for the severe final examinations in one of the universities where the lecture-examination system is used.

There are certain features in the lecture system which are of advantage in the development of the instructor. To lecture properly a professor must have his subject well in hand, and, on the whole, he requires a much broader grasp of it than he who teaches from a text-book. While only few men make first-class teachers, I believe there are many men who might pass as teachers who would be complete failures at lecturing. A lecturer, as a rule, aims to eliminate all material not essential to the proper exposition of his subject, and when the subject is properly presented the student carrying a heavy course absorbs and remembers the outstanding features of the subject without having them obliterated by a great mass of unnecessary text-book details. It may be said that when the material is thus presented the student neglects collateral reading and the charge may be made that students educated under the lecture system are deficient in this line of study because the lectures usually contain the information demanded by the examination papers. If the lecture course is properly conducted, however, it is easier to require collateral reading than when a text-book is used, because the student may become familiar with the text assigned, but it is difficult to persuade him to go beyond its covers.

While the lecture system is employed in many of the universities and colleges of the United States the daily recitation of assigned

exercises is the more popular system of teaching. This system has factors in its favor as well as some objections. The reason why this system is more popular in this country is, no doubt, due primarily to the democratic nature of all institutions. There is a tendency to bring the instructors in the classroom nearer to the students and to do away with the aloofness in which English or German professors hold their students, and while this has certain advantages it also often has disadvantages in lowering the faculty from a dignified position in the eyes of the students. Along with this condition there exists a popular sentiment that many students should be graduated from the state institutions whether they wish to go through college or not. It is not at all to be inferred from this statement that all these state institutions have low standards of scholarship, but rather that a student who is continually coached along by an instructor will finally graduate who never would graduate if left to his own resources. It is believed, however, that a rigid examination system would cull out a lot of these men and that a lower percentage of mentally poor students would graduate under such a system. Another reason suggested for the popularity of the recitation method in this country is the fact that many of the students entering college are younger and less mature, from an academic standpoint, than in some other countries and they therefore require more personal assistance from their instructors. The greatest factor in favor of the recitation method—and there are those who regard this of sufficient importance to offset all objections—is that if a teacher be at all efficient even a slow student must get a fairly clear idea of the subject studied. On the other hand, the recitation is liable to degenerate in colleges to a grade-school system of instruction. Where daily recitations are required the student who recites satisfactorily is quite justified in demanding that the results of these responses play an important part in the calculation of his credits and the result is that many instructors spend too much of their time grading the students instead of giving them the fundamentals of the subject.

If the professor requires recitations on an assigned exercise he must demand that every student respond to a satisfactory degree, because a student's failure to recite for several successive periods has a demoralizing influence on the class as a whole. The professor is therefore obliged to resort to some means of forcing an inefficient student to prepare his work, and in many institutions rash criticisms or severe sarcasm are employed even in dealing with mature postgraduate students. Influences of this sort tend to lower the dignity of the faculty, and, as a rule, little is gained, because a man who will not do his best in college, at least after he has passed his first year, is seldom of much use after he leaves the institution. If he be doing his best nothing more should be expected of him; the results of his work reflect upon himself. The system of questioning students is being carried to such an extreme in this country that text-books are sometimes issued which contain the interrogatives, "why" and "how," inserted in the body of the text, thus taking away from the instructor the credit for having enough ability and initiative to ask necessary questions and develop the subject as a teacher with any enthusiasm or knowledge of the subject might wish to develop it. Fortunately such texts are designed chiefly for use in the grade schools.

In conclusion it may be said, as a result of observations in the different countries mentioned, that the chief objections which can be made to the lecture and rigid examination system are that it is hard on the weak student and gives the profligate too much freedom. As a rule it cultivates a greater independence of action and at the same time places the faculty in a more dignified position in the eyes of the students. It is the best system for imparting a broad knowledge and promoting enthusiasm for a subject.

The recitation of assigned text-book exercises assists the student who is mentally weak, as he can thus get a clearer grasp of the subject. This method is the most desirable for teaching subjects in which reference is made to a large amount of technical details, and it

is no doubt better for the average student during his first year in college, since his actions may be more carefully observed by the members of the faculty.

To offset the tendency of many young students who are away from home for the first time, to be led astray by the freedom and glamor of college life, some American colleges and universities have adopted the Freshman Adviser system. With this scheme the freshmen are divided into groups and each group assigned to some member of the faculty, preferably an instructor of experience, who acts as a counsellor and adviser to the students in his charge. If the paternal interest be wisely exercised many students may be started right in college life and succeed where otherwise they would fail, and the system becomes a great help to students and faculty. There is often a tendency, however, in the smaller institutions, for the advisers to pamper the students and make them as dependent as they would be in a preparatory school. The writer would, therefore, recommend this system, in a properly restricted form, as an excellent addition to the administration of a college or university in which the freedom of a lecture system permits the ignorant and immature student, away from guardianship for the first time, to develop bad habits which lead to undesirable excesses and a careless attitude towards his academic duties.

E. S. MOORE

#### THE KAHN FOUNDATION

"THE Kahn Foundation for the Foreign Travel of American Teachers" has issued Vol. I, Nos. 1 and 2, of its "Reports." The benefaction is unique enough to be interesting, and broad enough to invite debate, if not criticism. The deed of gift, dated January 6, 1911, was executed by Mr. Albert Kahn, of Paris, who had already founded *bourses de voyage* in France, Germany, Japan and England, and who contemplated similar action in Russia, China "and elsewhere." The trustees are Mr. Edward D. Adams, of New York City, or a successor to be nominated by the founder or by his personal representatives;

the President of Columbia University; the President of the American Museum of Natural History; the President of Harvard University; the Secretary of the Smithsonian Institution; or their respective successors. The purpose, which seems to be somewhat indefinite, is stated as follows:

For each year . . . the trustees shall in their discretion select two or more American teachers, scholars or investigators . . . preferably from the professors of such American colleges or universities as the trustees may from time to time designate . . . who will enter into and appreciate the spirit of the foundation and look upon their travels as preparation for the performance of high duties in the instruction and education of the youth of their country, and not as affording a mere vacation or pleasure trip. . . . The founder suggests that the itinerary of such travelers shall be regulated by the trustees in their discretion and shall, if deemed practicable, involve an absence from America of at least one year and include the various countries of Europe and Egypt, India, China, Japan, Ceylon and Java. The founder further suggests that each recipient of a "bourse de voyage" shall agree to furnish to the trustees a report containing the impressions and results of his travels, which report shall not exceed fifty printed pages. The reports of these travelers may be published by the trustees . . . or by the founder, in Paris, at his own expense.

The benefaction amounts at present to \$3,000, and four fellows have been appointed.

In 1911-12, the beneficiaries were Dr. Francis Daniels, professor of Romance languages in Wabash College, and Dr. J. H. T. McPherson, professor of history and political science in the University of Georgia; for 1912-13 they are Dr. William E. Kellicott, professor of biology in Goucher College, and Dr. Ivan M. Linforth, assistant professor of Greek in the University of California. The "Reports" before us are those of Drs. Daniels and McPherson. Dr. Daniels carried out the letter of the deed, going *via* Great Britain, Europe and Egypt to the Orient, visiting Ceylon, India, the Malay Peninsula, Hong Kong, China and Japan, returning thence to San Francisco. Dr. McPherson confined himself to Europe, with the purpose of acquaint-

ing himself with the methods and *status* of instruction in his own field, and of informing himself on "the progress of public opinion in regard to international arbitration." The report of Dr. Daniels is a most interesting series of "reactions" to the endless succession of scenes and people that passed before him. It is notable for its tart remarks on the Germans, for its complimentary references to the English, and for its conclusions, which run thus:

Three facts particularly struck me in my journey through the Orient. The first is the political and industrial might of Great Britain. . . . The second fact is that the Asiatics are more highly civilized than one dreams of before making the journey. . . . The third fact is the supremacy of American influence in China and Japan.

Dr. McPherson devotes more attention to educational affairs, but, like Dr. Daniels, has some hard words for the Germans. He found Paris the most profitable place he visited, and he says:

If I shall ever be so fortunate as to have a year to devote to historical study abroad, I shall prefer Paris to either Berlin or Oxford.

More to the point, perhaps, is his final question.

And now it is only fair to face the question, what assurance can I give the trustees that as a consequence of my year abroad the purposes of the trust and of the founder are to be promoted?

He interprets these purposes as two—"to promote the cause of civilization by rendering the beneficiaries better qualified for . . . their high duties . . . and to further international comity by helping to dispel provincial prejudice and ignorance." In other words, he infers that research is no principal object of the Kahn Foundation. In this he is probably right. For the arc of travel contemplated by the founder would appear to place the residence necessary for investigation out of the question. On the other hand, American college professors, as a class, are so accustomed to European travel in any case, that there would not seem to be much need for fresh stimulus in this direction. It might be suggested, therefore, that, if the foundation is to

fill a distinct niche, the objective should be to enable American teachers to acquaint themselves with the Orient. The undoubted influence of the United States upon Japan in the past, and her growing influence in China today, to say nothing of the Philippine situation, might well serve to indicate to the trustees this more definite idea of the main purpose of the benefaction. As matters stand, the aim is too nondescript to induce confidence.

R. M. W.

#### THE NATIONAL CONFERENCE COMMITTEE

THE sixth conference of the National Conference Committee on Standards of Colleges and Secondary Schools was held at the rooms of the Carnegie Foundation, 576 Fifth Ave., New York, N. Y., on February 19, 1913. The following delegates were present, representing the organizations indicated:

Headmaster Wilson Farrand, Newark Academy, representing the College Entrance Examination Board,—*Vice-president*.

Professor Frank W. Nicolson, Wesleyan University, representing the New England College Entrance Certificate Board.

Dean Herman V. Ames, University of Pennsylvania, representing the Association of Colleges and Preparatory Schools of the Middle States and Maryland.

Principal Frederick L. Bliss, Detroit University School, representing the North Central Association of Colleges and Secondary Schools.

Dean Frederick C. Ferry, Williams College, representing the New England Association of Colleges and Preparatory Schools,—*Secretary-treasurer*.

Secretary Clyde Furst, as substitute for President Henry S. Pritchett, representing the Carnegie Foundation for the Advancement of Teaching.

Dr. Kendric C. Babcock, specialist in higher education in the National Bureau of Education, as substitute for Hon. Philander P. Claxton, the United States Commissioner of Education.

Dr. George E. MacLean, president of the committee from its establishment in 1906 until 1912, was present by special invitation. The National Association of State Universities and the Association of Colleges and Preparatory Schools of the Southern States were not represented at the conference. The meeting was called by Vice-president Wilson Farrand, who presided at both the morning and the afternoon sessions.

A sub-committee reported the results of an investigation of the use of the terms "honorable dismissal" and "statement of record," which it had made by individual conference and by means of a questionnaire sent to eighty colleges and universities. This report stated that there was a general agreement among the colleges and universities as to the desirability of a standardization of these phrases, as to the acceptance of a student's freedom to continue in the institution issuing the transfer papers as the criterion for the granting of such papers, and as to the great advantage of entire frankness of statement in the issuance of them. The report contained also a resolution defining the proper use of these terms which, after slight modification, was adopted in the following form:

*Resolved*, That the term "honorable dismissal" should be used to refer to conduct and character only, and that honorable dismissal should never be given unless the student's standing as to conduct and character is such as to entitle him to continuance in the institution granting the dismissal. Furthermore, there should in every instance be given, in the statement of honorable dismissal, full mention of any probation, suspension or other temporary restriction imposed for bad conduct, the period of which restriction is not over when the papers of dismissal are issued.

That the term "statement of record" should be used to refer to the recorded results of a student's work in the classroom, and that this statement should in every instance contain all the important facts pertaining to the student's admission, classification and scholarship. In particular, no partial or incomplete classroom record (for example, with failures omitted) should ever be given without clear evidence that it is partial or incomplete; if the student's scholarship has been such as to pre-

vent his continuance in the institution issuing the statement of record or to render him subject to any probation, suspension or other temporary restriction, the period of which is not closed at the date of the record, a plain statement of any and all such facts should be included; and such information should be given as will make clear the system of grades employed, the number of exercises per week devoted to each course, etc.

The same sub-committee presented a review of some of the difficulties found in the application of the definition of the unit adopted by the committee at its meeting of October 9, 1909, and proposed a resolution providing for the addition of a paragraph to the explanatory statement then formulated. This resolution was adopted so that the entire definition of the unit now stands as follows:

A unit represents a year's study in any subject in a secondary school, constituting approximately a quarter of a full year's work.

This statement is designed to afford a standard of measurement for the work done in secondary schools. It takes the four-year high-school course as a basis, and assumes that the length of the school year is from thirty-six to forty weeks, that a period is from forty to sixty minutes in length, and that the study is pursued for four or five periods a week; but, under ordinary circumstances, a satisfactory year's work in any subject can not be accomplished in less than one hundred and twenty sixty-minute hours or their equivalent. Schools organized on any other than a four-year basis can, nevertheless, estimate their work in terms of this unit.

A four-year secondary school curriculum should be regarded as representing not more than sixteen units of work.

An ambiguity in the interpretation of the definition of the admission Latin requirement announced by the Commission on College Entrance Requirements in Latin in October, 1909, having been brought to the attention of the committee, it was decided to send communications to the chairman of that Commission, to the American Philological Association, and to the College Entrance Examination Board asking that steps be taken to remove the difficulty by an authoritative pronouncement on the subject.

The committee considered the question of the assignment of unit values to the new definition of the admission requirement in English and voted that, as a tentative arrangement, equal values be given to (1) the grammar and composition, and (2) the reading.

Among the questions assigned to a sub-committee for consideration and report at the next meeting are the following: the literal interpretation of the definition of the unit; the greater unit value of the work of the latter years of the secondary school curriculum as compared with the work of the earlier years; the effect on the unit value of work in any subject when it is accompanied or preceded by work in allied subjects; the assignment of unit values to the definitions of the admission requirements in the subjects, algebra, English and history; and the accrediting of candidates for admission to college from secondary schools which give instruction in only one foreign language.

Officers were elected for the year as follows: *President*, Headmaster Wilson Farrand, Newark Academy; *Vice-president*, President A. Ross Hill, University of Missouri; *Secretary-treasurer*, Dean Frederick C. Ferry, Williams College.

The sub-committee which had served for the past two years was continued for investigation and report at the next meeting. This committee includes Headmaster Wilson Farrand, Dean Frederick C. Ferry, President Henry S. Pritchett and Principal Frederick L. Bliss.

The next conference was appointed for February, 1914, or for such earlier time as the sub-committee might select.

FREDERICK C. FERRY,  
*Secretary*

#### THE DANA CENTENARY

In commemoration of the great geologic work of James Dwight Dana, Yale University proposes to hold a centenary celebration next November, to consist of a series of lectures culminating in a Dana Memorial volume on "Problems of American Geology." The lectures will be given on the Silliman Founda-

tion, the dates to be announced after the opening of the next collegiate year. The lecturers and their respective subjects are as follows:

#### PROBLEMS OF AMERICAN GEOLOGY

##### Introduction

"The Geology of James Dwight Dana," Professor William North Rice, Wesleyan University.

##### I. *Problems of the Canadian Shield*

"The Archeozoic and its Problems," Professor Frank Dawson Adams, McGill University.

"The Proterozoic and its Problems," Professor Arthur Philemon Coleman, University of Toronto.

##### II. *Problems of the Cordilleras*

"The Cambrian and its Problems," Dr. Charles Doolittle Walcott, Smithsonian Institution.

"The Igneous Geology and its Problems," Professor Waldemar Lindgren, Massachusetts Institute of Technology.

"The Tertiary Structural Evolution and its Problems," Dr. Frederick Leslie Ransome, United States Geological Survey.

"The Tertiary Sedimentary Record and its Problems," Dr. William Diller Matthew, American Museum of Natural History.

#### SCIENTIFIC NOTES AND NEWS

PRINCETON UNIVERSITY has conferred the degree of doctor of science on Dr. Simon Flexner, scientific director of the Rockefeller Institute for Medical Research and on Dr. David L. Edsall, Jackson professor of clinical medicine in the Harvard Medical School. The degree of master of arts has been conferred on Mr. William Barnum, editor of the publications of the Carnegie Institution.

THE Jefferson Medical College, Philadelphia, has conferred the degree of LL.D. on Dr. Abraham Jacobi, emeritus professor of diseases of children, College of Physicians and Surgeons, Columbia University, and on Dr. Francis P. Venable, president of the University of North Carolina.

DR. E. A. SCHÄFER, professor of physiology in the University of Edinburgh, has received the honor of knighthood. The same honor has been conferred upon Professor J. H. Biles, professor of naval architecture in the University of Glasgow.

THE Royal Dutch Geographical Society at Amsterdam has elected Professor W. M. Davis to honorary membership as "master in the art of organizing excursions in the old and the new world, and ingenious founder of a new system of geomorphology."

THE Portugal Academy of Sciences has elected Dr. L. A. Bauer a corresponding member.

ADMIRAL ROBERT E. PEARY lectured before the French Geographical Society on the evening of June 6, when the decoration of the legion of honor was conferred on him.

DR. HENRY W. FARNHAM, professor of political economy at Yale University, has been appointed Roosevelt professor at the University of Berlin by Columbia University and the University of Berlin.

PROFESSOR GEORGE A. HULETT, who has been on a leave of absence this year from Princeton University and has been acting as chief chemist of the United States Bureau of Mines, will return to Princeton in the fall, and resume his duties as professor of physical chemistry.

GEORGE W. LAMKE, assistant professor of electrical engineering at Washington University, and Chester H. Hardy, instructor in electrical engineering, have resigned their positions to take up active practise.

T. T. WATERMAN, assistant professor of anthropology in the University of California, will spend the summer in New York, in part to study the collections in the American Museum.

At the annual meeting of the American Medico-Psychological Association, which ended its sessions at Niagara Falls on June 13, Dr. Carlos F. MacDonald, of New York, was elected president, Dr. S. E. Smith, of Indiana, vice-president, and Dr. Charles G. Wagner, of Binghamton, N. Y., secretary. The association will meet in Baltimore in 1914.

THE eighth annual meeting of the American Association of Museums was held in Philadelphia, from June 3 to 5, 1913, with about one hundred members in attendance. Dr. Henry

L. Ward, of the Milwaukee Museum, presided. In addition to the reading of papers the program was so arranged as to provide time for the study of important museum collections at the Academy of Natural Sciences, University Museum, Commercial Museum, Wistar Institute of Anatomy, Academy of Fine Arts and Memorial Hall. The officers elected for the ensuing year are: President, Benjamin Ives Gilman, Museum of Fine Arts, Boston; Secretary, Paul M. Rea, Charleston Museum, Charleston, S. C.; Treasurer, William P. Wilson, The Commercial Museum, Philadelphia. The next annual meeting will be held in Chicago with a supplementary session in Milwaukee.

IMMEDIATELY after the resignation of professor Willis L. Moore as chief of the Weather Bureau had been accepted by the President, charges were filed against him with the Secretary of Agriculture by responsible men in the service. Those charges, which related to the improper conduct on the part of Professor Moore in connection with his candidacy for the office of secretary of agriculture, were of such a grave nature that the Department of Justice was asked to make an investigation. This investigation has now been practically completed. The facts secured from the preliminary investigation were sufficient to warrant the President in withdrawing his acceptance of Professor Moore's resignation and removing him summarily from the service, which was done April 16, 1913. Charles T. Burns, an employee of the Weather Bureau, was furloughed at the same time, but later reinstated with reduced rank and salary. On June 7, as a result of the investigation by the Department of Justice, six other employees of the Weather Bureau were furloughed without pay, and thirty-one other officers and employees whose salaries had apparently been increased by Professor Moore as a reward for their activities on his behalf were reduced to their former salaries.

PROFESSOR ALBERT PERRY BRIGHAM, of Colgate University, will go to Europe in July to remain during the coming academic year. In

his absence Professor Isaiah Bowman, of Yale University, will be the acting secretary of the Association of American Geographers and will prepare the program for the Princeton meeting. Professor Bowman is expected to return from South America in September.

PROFESSOR HOWARD S. REED, of the Virginia Polytechnic Institute, who is spending the year in Europe was a delegate to the Tenth International Congress of Agriculture held in Ghent from June 8 to 12.

ARTHUR H. BLANCHARD, professor of highway engineering in Columbia University, sailed on June 12 to attend the Third International Road Congress, London. Professor Blanchard is a United States reporter on Question 3, "Construction of macadamized roads bound with tarry, bituminous, or asphaltic materials," and Communication 10, "Terminology adopted or to be adopted in each country relating to road construction and maintenance." He has been appointed a delegate to the congress by Columbia University, the American Society of Civil Engineers, the National Highways Association and the American Road Builders' Association.

A SPECIAL research meeting was held by the Royal Geographical Society of London, on June 4, at which Dr. L. A. Bauer gave an account of the progress of the magnetic survey of the oceans and of the chief results thus far obtained. The paper was discussed by Sir David Gill, the presiding officer, by Drs. Shaw and Chree, and by Captain Creak and others.

PROFESSOR H. H. DONALDSON, of the Wistar Institute of Anatomy and Biology, Philadelphia, delivered the commencement address at the St. Louis University School of Medicine on June 5, the subject being "The Mutual Relations of Medical Progress and the Physician."

THREE Chadwick public lectures, on "Nature and Nurture in Mental Development," are being given by Dr. F. W. Mott, F.R.S., at the Royal Society of Arts, on June 6, 13, and 20.

MR. FREDERICK ALBION OBER, an explorer and the author of works on ornithology and

travel, died in Hackensack, N. J., on June 1, aged sixty-four years.

PROFESSOR L. G. LEÓN, general secretary of the Mexican Astronomical Society, has died at the age of forty-seven years.

THE death is also announced of Dr. Léon Pervinquière, lecturer on paleontology in the University of Paris.

MR. ARTHUR JAMES has given as a memorial to his brother the income of a sum of 20,000*l.* for cancer research to the Middlesex Hospital, London.

THE Bureau of Standards, Department of Commerce, expects to begin, soon after July 1, the inspection of railroad scales, starting with some of the scales of the eastern roads. This test will be made as a result of complaints from shippers as to the weights charged for by railroads, which have recently drawn attention to the necessity for some governmental supervision over railroad track scales, as well as scales used by shippers doing an interstate business. Every grocer's scale is supposed to be tested as to its accuracy periodically in order that the purchasers may be assured of getting correct weight. In addition, the city or county sealer sees to it that the purchaser secures full weight or measure, and prosecutes violations of the law by the dealers. On the other hand, the railroads annually collect approximately \$2,200,000,000 from the shippers of the country on scales which belong to and are operated entirely by the roads, and over which neither the shipper nor the Government has any control or, indeed, any information as to the correctness of the scales. In order to secure information that will enable the Government to draw reliable conclusions as to what shall be done to guarantee the accuracy of railroad weights, and also for the purpose of aiding the railroads to install correct scales, the Bureau of Standards was allowed an appropriation of \$25,000 by Congress for the purchase of a test-weight car equipment. The contract for this car has already been let, and it is expected that the car will be delivered soon after July 1, when the appropriation becomes available. The equipment ordered by the

Bureau will differ radically in principle from any in use. Instead of the wheels, brakes, and other movable parts of the car constituting part of the standard weight, as is customary, the Bureau proposes to carry a series of 10,000-pound weights and a truck for moving them on the scales, in a specially designed car provided with a power crane and other accessories for handling the weights. The advantage of this arrangement is that the weights may be standardized and transported from one end of the country to the other with a reasonable assurance that they will remain constant, whereas if the running gear is included in the weight of the test car it would be necessary to verify this weight at frequent intervals. After testing a scale with the standard weights, the empty car may then be put on the scale and its weight determined, after which the weights may be loaded into the car and the scale tested up to the full capacity of the car plus the standard weights.

THE eighty-first annual meeting of the British Medical Association will be held at Brighton, July 22-25. According to the *Journal* of the American Medical Association in the section of bacteriology and pathology the papers will include one by Dr. Miller Galt on "The Value of the Blood-count in Obscure Bacterial Infections," and an account by the staff of the John Howard McFadden Research fund on "Some Researches on the Jelly Method of Staining Cells Alive." A joint discussion has been arranged with the section on pharmacology on "Anaphylaxis," the papers promised including a consideration of "The Action of Asbestos and other Finely-divided Substances on Various Physiologic Substances." In the section of climatology and balneology there will be discussions on "Sea Bathing," to be opened by Dr. W. J. Tyson, and on "The International Aspects of British Health Resorts," to be opened by Dr. Neville Wood. In the section of diseases of children, Dr. E. J. Poynton and Dr. Carey Coombs will initiate a debate on the "Affections of the Heart in Childhood." In the section of electrotherapeutics papers and discussions have been arranged on "Rönt-

gen Diagnosis," on "Electrodiagnosis and Electrotherapeutics" and on "Röntgen Therapy and Radium." The subjects chosen for discussion in the section of medical sociology are "Crime and Punishment," on which Dr. Charles Mercier, Sir Bryan Donkin and Dr. James Scott will read papers, and on "Hospitals in Relation to the Stage, the Public and the Medical Profession," in which Sir Henry Burdett and Dr. I. G. Gibbons will read papers. The discussion will, it is hoped, prove valuable in helping to elucidate the problems involved in providing hospital accommodation for insured persons under the national insurance act. A discussion on "Eugenics" will be introduced by Professor Bateson, to be followed by Dr. Stewart Mackintosh, and Mr. Chas. B. Davenport, of New York. The arrangements for the navy, army and ambulance sections include a paper by Major Birrell on "Notes on the Work of a British Red Cross Unit with the Bulgarians."

A BRITISH Blue Book has been issued giving statistics of the number of persons killed by wild animals and snakes in British India from 1880 to 1910. According to the summary in the *British Medical Journal* the figures show that the tiger is the animal most destructive to human life; during the last five years of the period it was responsible for 38 per cent. of the total number of deaths caused by wild animals, leopards accounting for 16, wolves for 12 and bears for 4 per cent. Of the total number of persons (2,382) killed by wild animals in the year 1910, the tiger accounted for 882, the leopard for 366 and wolves and bears for 428. Elephants and hyenas, the two other animals distinguished in the returns, were between them responsible for 77 deaths in 1910. Of the 629 deaths attributed to "other animals," 244 are assigned to alligators and crocodiles, 51 to wild pigs, 16 to buffaloes, 24 to wild dogs and 220 to unspecified animals. In 1910 there were 22,478 deaths from snake-bite, compared with 21,364 in the previous year, but Bombay was one of the provinces which did not contribute towards the increase, and is in other respects one of the more fortunate parts of India. In Bengal, for ex-

ample, 1,130 persons were killed in 1910 by wild animals and 7,767 by snakes; but Bombay is, with the exception of the Punjab, at the bottom of the list with 22 deaths by wild animals and 1,247 by snakes. The statistics regarding the number of cattle killed by wild animals are not very perfect, but it is estimated that in the five years ending 1910 the number of animals killed was about 100,000, leopards accounting for 48 per cent. and tigers for 32 per cent.

#### UNIVERSITY AND EDUCATIONAL NEWS

COLUMBIA UNIVERSITY, Rutgers College and the Reformed Church in America receive bequests which may amount to \$1,000,000 each as the three principal beneficiaries under the will of Mrs. Mary B. Pell, who died on May 26 at 182 Riverside Drive, and was the widow of John H. Pell. Each beneficiary received a direct bequest of \$200,000 and an interest in large trust funds aggregating more than \$2,000,000. The bequest to the Reformed Church is for the purpose of building the Wessels Memorial Hall at the theological seminary at New Brunswick, N. J., and the same name is to be adopted for a memorial hall to be erected with the bequest to Rutgers. The fund for Columbia is to erect Pell Hall, in memory of the decedent's husband, who was an alumnus of Columbia.

PRINCETON UNIVERSITY has received \$100,000 from Mrs. Russell Sage toward the construction of a dining hall.

GOVERNOR SULZER has signed bills appropriating \$450,000 for the College of Agriculture of Cornell University, which also receives \$125,000 in the supply bill. The appropriation for the veterinary college is \$70,000. A part of the additional appropriation this year is to be used for increasing salaries.

THE bill taking over the College of Physicians and Surgeons by the University of Illinois was advanced to its third reading in the legislature, on June 5, after the defeat of amendments offered by those opposing the project. The state is being asked to appropriate \$200,000 for maintenance of the institution,

this being a part of the \$4,300,000 appropriation asked for the University of Illinois.

THE Plant Industry Hall of the University of Nebraska, containing the departments of agricultural botany, entomology, experimental agronomy and horticulture was dedicated on June 10, the address being made by Professor John M. Coulter, professor of botany in the University of Chicago.

THE following appointments have been made to the faculty of the new school of technology of the Johns Hopkins University: Professor C. C. Thomas, of the University of Wisconsin, to the chair of mechanical engineering; Professor C. J. Tilden, of the University of Michigan, to the chair of civil engineering; and Professor J. B. Whitehead, hitherto professor of applied electricity in Johns Hopkins University, to the chair of electrical engineering.

E. DANA DURAND, former director of the United States Census, has accepted the position of director of the Bureau of Research in Agricultural Economics, at the Minnesota Agricultural College.

PROFESSOR PIERRE BOUTROUX, of the University of Poitiers, France, has been elected professor of mathematics at Princeton University.

DR. R. G. HOSKINS, Ph.D. (Harvard, '10), has been appointed associate professor of physiology in the Northwestern Medical School. Dr. Hoskins, who has been working on internal secretions, will devote three fourths of his time to research and one fourth to teaching.

CHARLES T. KIRK, Ph.D. (Wisconsin, 1911), has been appointed professor of geology in the University of New Mexico. According to the State law of 1909, establishing a Natural Resources Survey, Mr. Kirk becomes ex-officio state geologist, and will spend the present summer in reconnaissance work in that capacity, with headquarters at Albuquerque.

DR. EDWARD C. DAY, Harvard foreign fellow, Naples, Italy, has been elected instructor in zoology, Syracuse University. Dr. M. W. Blackman, of the department of zoology, Syracuse University, has been elected associate professor of entomology in The New

York State College of Forestry, Syracuse University.

At the Alabama Polytechnic Institute, Auburn, Alabama, changes in the staff have occurred as follows: Dr. E. P. Sandsten, professor of horticulture and state horticulturist, resigns to accept a similar appointment in Colorado State College. A. B. Massey, formerly assistant professor of botany and bacteriology in Clemson College, becomes assistant professor of botany. H. N. Conolly, field agent in horticulture, resigns to accept similar work in Colorado State College. Charles S. Williamson, Jr., formerly assistant professor, is promoted to associate professorship in the department of chemistry. Jesse M. Jones is appointed head of the department of animal industry, succeeding Dan T. Gray, who has accepted a similar position in the North Carolina Agricultural College.

THE Board of Agricultural Studies of the University of Cambridge, in consultation with the president of the Royal Agricultural Society, has nominated Mr. C. R. Fay, M.A., Christ's College, to be the Gilbey lecturer on the history and economics of agriculture.

#### DISCUSSION AND CORRESPONDENCE

##### THE CHARACTER OF THE ENDOSPERM OF SUGAR CORN

IN a recent publication<sup>1</sup> dealing with the  $F_2$  generation of a cross between two forms of *Zea Mays*, the one with sugar endosperm, the other with waxy endosperm, the existence of two alternative factors, one for sugar ( $S$ ), the other for waxy ( $X$ ) is assumed. Absence of  $S$  results in waxy endosperm, absence of  $X$  results in sugar endosperm. When both are present a horny endosperm results. The  $F_1$  generation, involving 22,132 kernels, consisted of those with horny, waxy and sugar endosperm in a proportion closely approximating the 9:3:4 ratio.

The assumption of two alternative factors

<sup>1</sup> Collins, G. N., and J. H. Kempton, "Inheritance of Waxy Endosperm in Hybrids with Sweet Corn," U. S. Dept. Agric., Bur. Pl. Ind., Circular 120, 1913.

does not meet the requirements, since on this basis a ratio 9:3:3:1 is to be expected. On the basis of Mr. Collins's theory, too, a zygotic construction  $ssxx$ , involving  $\frac{1}{16}$  of the  $F_2$  generation should result in neither a waxy nor a sugar endosperm. Yet the numerical results clearly indicate a sugar endosperm for this portion of the  $F_2$  generation. ("Careful scrutiny of the sweet seeds failed to show any consistent differences that would allow another class to be separated, . . .").

A more plausible explanation suggests itself in an analogy to Cuénot's hybrids between agouti and albino mice. Assuming a basic factor  $S$ , responsible for the sugar endosperm, a factor  $W$ , which, acting together with  $S$ , produces a waxy endosperm, and a modifying factor  $H$ , which acting together with the factors  $W$  and  $S$  produces a horny endosperm, I would suggest for the zygotic constitution of sugar corn  $HHwwSS$ , and for the zygotic constitution of *Zea Mays* with waxy endosperm  $hhWWSS$ . On this basis the  $F_1$  generation of a cross sugar  $\times$  waxy should possess the zygotic constitution  $HhWwSS$ , which, according to our premises, should result, and in fact does result, in a horny endosperm. Selfing of the  $F_1$  generation should yield the following combinations:

$HWS$ $HWS$	$HwS$ $HWS$	$hWS$ $HWS$	$hwS$ $HWS$
$HWS$ $HwS$	$HwS$ $HwS$	$hWS$ $HwS$	$hwS$ $HwS$
$HWS$ $hWS$	$HwS$ $hWS$	$hWS$ $hWS$	$hwS$ $hWS$
$HWS$ $hwS$	$HwS$ $hwS$	$hWS$ $hwS$	$hwS$ $hwS$

The combinations  $HHWWSS$  (1),  $HHWwSS$  (2),  $HhWWSS$  (2) and  $HhWwSS$  (4), should result in a horny endosperm, since they contain all three factors; the combinations  $HHwwSS$  (1),  $HhwwSS$  (2) and  $hhwwSS$  (1), should yield a sugar endosperm, since the factor  $W$  is lacking, and the combinations  $hhWWSS$  (1) and  $hhWwSS$  (2) should produce a waxy endosperm, since the modifying

factor  $H$  is lacking. Therefore horny, sugar and waxy endosperm should be represented in the proportions, actually found, 9:4:3.

To test for the presence or absence of the factor  $H$ , here suggested, in sugar-corn a cross should be made with homozygous waxy. Three kinds should be found, the first ( $HHwwSS$ ) yielding horny endosperm only, the second ( $HhwwSS$ ) yielding 50 per cent. horny and 50 per cent. waxy and the third ( $hhwwSS$ ) yielding waxy only.

UNIVERSITY OF MICHIGAN

#### THE YELLOWSTONE PARK

TO THE EDITOR OF SCIENCE: In a letter relating to Yellowstone Park which appeared in the issue of SCIENCE for March 21, 1913, there were some statements concerning the experiences which tourists camping out in the park ("sage-brushers," they are usually called) have with the bears, which are certainly astonishing to those who can speak for the sagebrushers if not for the bears. The "cleaning out of sagebrushers' camps by marauding bears" was spoken of as a "nightly occurrence" and it was stated that "three or four sagebrushers are killed nearly every summer in attempting to drive bears out of their camps." My experience as a sagebrusher is that bears will indeed attack the vulnerable part of the camp—the locker containing the store of bacon and the lard can—but even in the vicinity of the Canyon of the Yellowstone, where bears are most numerous, the repelling of an attack on the larder took on much the nature of a midnight sally to rout the neighbor's cow from one's garden patch. There was the same spontaneous rallying against the invasion, the violent laying about with whips and clubs, the resort to loud and picturesque language, and the same clumsy and precipitate retreat of the culprit. Once only we thought it necessary to resort to extreme measures which was to play upon the invaders with a Roman candle. This was completely effective. I would not have a single person miss the great fun and

superior advantage of camping out during the tour of the park because of the fear of the bears.

A statement from Lieutenant Colonel L. M. Brett, acting superintendent of the park, under date of April 5, 1913, should certainly reassure all who contemplate a camping trip. I quote as follows:

As a matter of fact, no tourist or other person has ever been killed by a bear in the park, so far as is known in this office. Our regulations prohibit feeding or meddling with bears, but it is a great temptation for every one to feed them and make pets of them, and the regulations are sometimes violated. Otherwise, there would seldom be any bad bears in the park. As it is, we have instances where the bear becomes dangerous to life and property, and it is necessary to dispose of it. This is done by capture alive and shipment by express to some city zoo, when there is a demand for a bear, and in case there is no demand for it, it is shot. A few instances are on record where people have been attacked and injured by bears. One of these was a tourist; the others were employees of hotels, etc., in the park. In all cases where the facts were known, the person injured was more or less to blame for his own misfortune.

JESSE L. SMITH

#### THE METRIC SYSTEM OF WEIGHTS AND MEASURES

TO THE EDITOR OF SCIENCE: I agree with all that Professor A. H. Patterson says regarding the greater simplicity and general desirability of the metric system of weights and measures, but there is, perhaps, something that may be profitably said concerning his reference to "those selfish interests which are blocking the way of reform."

Chief among these interests, perhaps, are the machinery-making concerns of the country, and if Professor Patterson were responsible for the conservation of the capital invested in measuring tools, gauges, fixtures, etc., based upon the present system of measurement, and if he believed that a change to the metric system would make it necessary to discard these tools and gauges, he would, I fear, be strongly tempted to object to the introduction of the metric system, notwithstanding his perception of its superiority.

The very general objection of the American machinery constructors to the introduction of the metric system is based upon the belief that the capital above referred to would be thereby sacrificed. A curious feature of the case, however, is that it has been, and can at any time be demonstrated that no such sacrifice would be involved, and therefore the serious objection, which comes from machinery-building interests, to the taking of any step toward the introduction of the metric system, is based upon an entire misconception. This misconception is due chiefly to the fact that most machinery manufacturers do not themselves take the time and trouble necessary to look into this matter, but have taken at par the statements of one or two extreme opponents of the present heterogeneity called a system. These opponents have represented and have made many others believe that the change to the use of the metric system would necessarily mean an alteration in the actual dimensions of machinery now built, and of the tools used in connection with that machinery.

The fact that machinery-building establishments in this country are regularly using the metric system, and are applying it to the identical machines previously made to the English system, without any alteration whatever in the machines themselves, or in the tools for making them, seems to have no weight, and because a matter of dollars and cents is involved, and deep-seated prejudices have been aroused, practically no hearing can be obtained for the manifest advantages of the metric system. The columns of the trade journals are practically closed to all discussions of it, and whenever the subject is up for discussion, by a committee of congress, representatives of, or those professing to represent, the machinery-building interests, will oppose any step taken toward progress in this matter.

Even when it was proposed simply that the various departments of the United States government should make use of the metric system, it was strenuously opposed on account of what it was feared it would lead to, although it was evident that whatever of extra

expense might have been involved in the use of the metric system by the government departments would have been borne by the government itself, and would, therefore, have been distributed in such a way as to have been unperceived; even granting that there would have been any extra expense, which is by no means demonstrated and is doubtful.

I mention this matter only to show what the nature of the opposition to the metric system is, and from whence the strength of such opposition comes. It is based upon primary considerations which would be justifiable, or at least quite excusable, if there were any foundation for them. It is my belief that there is practically no foundation for them.

FRED J. MILLER

#### THE TEACHING OF ENGLISH COMPOSITION

TO THE EDITOR OF SCIENCE: I sympathize with Professor Robinson in his concern over the unhappiness of the teacher of English composition, and approve of all he says; but he does not go far enough. He does not answer his own question: "What are we to do to keep him [the teacher] happy in English composition?"

He divides the men in charge of classes in English into two types: the "educator"—who "draws out" his pupils, reads themes less and plays golf more, and from whom the students draw culture in the vaguer sense, a dissemination of sweetness and light—and the "teacher," whose conference work is "confined mostly to grammar, punctuation and the split infinitive; but in the class he finds nothing to do that he considers worth while."

It is a common fault of teachers and of scientific men that they are always trying to divide things, and men, into types and classes, to put them into pigeonholes and label them. What Professor Robinson should do is to try to discover a man who combines the best characteristics of both "educator" and "teacher" and who can not be put in the pigeonhole with either label. If there is no such man to be found, perhaps one can be made. Start with a "teacher" who "hates inexactness and vagueness," and "loves to enforce a clear

intellectual distinction." Make him drop his conferences on "punctuation, grammar and the split infinitive" (I suppose the last two words refer to the latitude of Boston; the rest of the country does not bother itself about the split infinitive) and let his students "criticize their own compositions and those of one another" on these points, as the "educator" does. Let him "read themes less and play golf more," and let him, like the "educator," disseminate the culture of sweetness and light. Give him the right kind of a text-book, with some logic in it, even with the "Barbara, Celarent"—which is a good thing to have in the text-book for reference, although it need not be memorized.

Why should not such a man be found? A teacher, or an educator, like every other man, is the product of heredity and environment, also of habit and of the kind of boss he has—which last may be considered part of his environment. The heredity of the teacher, in Boston at least, is all right; his environment is fairly good, but his teaching habits are bad and he has not been properly bossed; therefore he is unhappy. He is supposed to be teaching English composition, but he is not; he is reading "themes" and correcting errors of grammar and punctuation; he is doing the work that should have been done in the grammar school. "This man of solid thoughtful mind is the only real teacher." Yes, but he is unhappy, and he needs a boss to direct him how and what to teach, and how to "educate," and how to be happy, though a teacher.

Can a boss be found? Why not? Is there not in Harvard some authority that can get the "teachers" and the "educators" together around a table and say to them: "Show us the results of your teaching and educating. Do your graduates have 'mechanical perfection in technique' and there stick; have they style, or do they 'write with the mechanical regularity of one pumping into a bucket'? What proportion of them write even passable English? If the results are not what they should be, get together, you teachers and educators, and plan a better method. If you

can not plan one, do as the football players do, hire a coach to plan the method, and let him be your boss until you can show results with it."

"Some day there will be a shaking among these dry bones." Why not now?

WILLIAM KENT

MONTCLAIR, N. J.

#### UNIVERSITY LIFE IN IDAHO

TO THE EDITOR OF SCIENCE: Permit me to state, in reference to the question of veracity between President James A. MacLean, of the University of Manitoba, and Professor V. L. Kellogg, of Stanford University, that at the request of Professor Kellogg I furnished him with a rather full statement of the facts concerning my recent separation from the University of Idaho. From what I wrote him he prepared his article published by you under the caption "University Life in Idaho." It contains no material statement not furnished by me, and none which I do not at the present time fully believe to be true, notwithstanding President MacLean's denial. In fact, most of the details are matters of common knowledge, which no one could deny in Moscow, Idaho, though it might be done in Winnipeg.

As it is obviously impossible to try the case in your columns, I must be content to assume full responsibility for the essential correctness of Professor Kellogg's article.

#### SCIENTIFIC BOOKS

*The Space-Time Manifold of Relativity, the Non-Euclidean Geometry of Mechanics and Electromagnetics.* By EDWIN B. WILSON and GILBERT N. LEWIS. Proc. Amer. Acad. Arts and Sci., Vol. 48, No. 11. November, 1912. Pp. 120.

Probably the most startling scientific conclusion of the past was the assertion that the earth moved. Even yet, while every one would probably assent passively to this state-

ment, it is doubtful if many persons actually construct their idea of the universe so as to make this motion of the earth a reality. It is not many years since the assertion of Poincaré that the rotation of the earth is a hypothesis, met with as much glee in some quarters as it did astonishment in others. When the average man says that so far as he is concerned, the earth is stationary, he means practically that none of the experiences he has had lead him to think of the earth as in motion. When, however, he becomes a physicist, and tries to harmonize the motion of Foucault's pendulum with his ideas of mechanics, or the deviation of a falling body from the vertical, or the motion of storms across the surface of the earth, he is led to assert as the simplest explanation that the earth must rotate. When he becomes an astronomer and endeavors to reduce the varying configurations of the heavens to some kind of simplicity, he is ultimately led to assert that the earth is moving in space. He is thus brought to consider the question, is the whole universe in motion? and how can its motion be detected? At once he remembers Archimedes's remark: Give me a fulcrum and I will move the world. What is the fulcrum? Here is the trouble. If the earth may be thought of as moving around the sun, the sun may be thought of as moving around the earth. If the mountains and oceans of the earth can turn smoothly around once every twenty-four hours why can not the heavens turn? The problem comes home and must be phrased thus: How can the absolute motion of the earth be proved? Was Galileo right when he said: *E pur si muove*.

We turn first to dynamics for help, but we find that its laws will not avail. The fundamental law is that the rate of change of the momentum of a moving body is proportional to the force acting, where force and momentum are taken as directed quantities. But if we locate the moving particle with respect to an origin which itself is moving uniformly in a straight line we can not detect the fact that the origin is in motion, for the law holds equally well in either case; that is to say,

change in momentum is measured by a difference of velocities and can never give us the absolute value of velocity itself. This is the relativity principle of ordinary mechanics. Conversely, if we agree that all we know of the kinetic energy of a particle is that the increment of the energy is measured by the work done by the external force in moving the particle an infinitesimal distance, and that this is invariant for a system whether it is at rest or in motion, with a uniform rectilinear velocity, then all the equations of dynamics are deducible from this basis.

Since dynamics gives us no help, we turn to electrodynamics. There is here a constant which seems to be an absolute constant, the velocity of light. It would seem that if light is a movement or a disturbance in a stationary ether, then we should be able to detect the motion of the earth against this ether. Aberration indeed seems to indicate that we have found our fulcrum. But other experiments seem to show that if there is an ether, it moves with the earth. And the only apparent way to reconcile all the experiments seems to be the assumption of certain laws which make the hypothesis of an ether superfluous. The physicist is here hard pressed for a satisfactory substitute. When the fundamental equations of electrodynamics are examined mathematically, it is found that certain changes can be made in the variables of these equations without affecting the form of the equations. In the new variables the equations read just the same as in the old. That is to say, for certain moving systems the equations are of the same form as for a stationary system. Consequently the quantities involved can only be determined relatively.

The specific statement of the case is this:

Let one end of our laboratory table be our origin, and we will suppose that with respect to an omnipresent stationary observer who appreciates distance and time directly, the origin is in motion in a straight line with uniform velocity,  $v$ . The velocity of light we will represent by  $c$ , and we will suppose that any velocity can be measured absolutely. This is our first assumption. Then if the fol-

lowing things happen to be facts, we can not ever hope to detect the absolute motion of the table by experiments on light or electricity.

1. If there is a bar  $AB$  on the table pointing in the line of the motion, to the stationary observer its length would be only  $AB\sqrt{(1-\beta^2)}$  where  $\beta = v/c$ .

2. The time on a clock at  $A$  on the table would read less in the same ratio, that is, if the motion began at noon, when the stationary observer knew that the time was really  $t$  the clock would read  $t\sqrt{(1-\beta^2)}$ .

3. A clock at  $B$  could not be made to read the same as a clock at  $A$  at the same instant but would be behind that at  $A$  by

$$\frac{AB}{v} \frac{\beta^2}{(1-\beta^2)}.$$

If a clock were instantly moved from  $A$  to  $B$  the hands would instantly shift through that amount. This is the principle of *local time*.

The stationary observer would deduce at once some very startling conclusions, such as these. If the table could move with the velocity of light,  $\beta=1$ , and the length of  $AB$  would be nothing at all. The clock at  $A$  would cease to register time at all. The obvious conclusion would be that the velocity of light is a maximum that no velocity could ever reach. But even for velocities below that of light we have to give up the idea of incompressible bodies. Energy and mass become confused and physics has to be remade. And the difficulty of time being attached to the place at which we are, so that no time meter could be devised which could be moved around and retain its correct reading, is disturbing. If two clock faces are at the ends of a long axis, and read together when across the line of motion, why should there be a twist in the axis when it is turned into the line of motion?

To enable one to understand these proposed relations of distance and time, Minkowski conceived the notion of giving them a geometrical setting. This is nothing new in physics, for many models have been made to represent various laws and hypotheses. They enable us to look at the relations in a much more direct way; to be able, as it were, to look

over a map of the ground. It must be borne in mind, however, that such representations are not substitutions for the thing itself. A temperature-entropy diagram is not steam in a boiler, of course, but only shows certain relations as to the steam in the boiler. So too, Minkowski's geometric setting of relativity is not a picture of the world, but a representation of the relations that are set forth in the theory of relativity.

His suggestion was that if we use a four-dimensional space, measuring  $x, y, z$  (which give us the position of the laboratory table) along three axes, and measure on the fourth axis the distance  $ct$ , then the fourth axis can be spoken of as a time axis, since  $c$  is a constant. In this way we can speak of the situation of the real world at time  $t$  as a section in the four-dimensional world by moving a space of three dimensions. The idea is easily illustrated by imagining a wave on a pond made by a stone dropped into the water. The wave spreads out with a given velocity. If now we construct a cone of the proper angle, immerse the point at the center of the wave and let the cone sink at the right speed, the expanding wave will always remain in contact with the cone. Or, so far as geometry is concerned, we can keep the cone stationary and let a cutting plane move upward. The circular section on the plane will then appear to expand like a wave. In an analogous manner we can at least get a phraseology that will describe the ideas underlying relativity of the electrodynamic kind. It turns out that if we represent these in a four-dimensional space the whole statement of the relativity property can be summed up in one simple statement, that is: In the four-dimensional space the choice of our axes of reference is fairly arbitrary. We may take axes inclined at the proper angle to our original axes, as new axes of reference, and the equations for the new  $x', y', z', t'$ , are just like the original equations. Indeed if we suppose the table mentioned above to move along the  $x$  axis, as viewed by a stationary observer, with a uniform velocity  $v$ , which we may set equal to  $c \tanh \phi$ , where  $\tanh \phi = \beta$ ,  $\tanh^2$  being the

symbol for hyperbolic tangent, we may write the equations of transformation in the form

$$\begin{aligned}x &= x' \cosh \phi + ct' \sinh \phi, \\ct &= x' \sinh \phi + ct' \cosh \phi.\end{aligned}$$

That is, if one end of the table, say  $B$ , is apparently to the moving observer at a distance  $x'$  ahead of the other end, which is the moving origin,  $A$ , then the stationary observer knows that the real stationary distance is  $x' \cosh \phi$ . If the clock at  $B$  reads  $t'$  to the moving observer, then the stationary observer knows that the time which has elapsed from the beginning of the motion is really  $t' \cosh \phi$ ; and at velocity  $v$ , this means that the origin  $A$  has moved away from the stationary origin a real distance  $vt' \cosh \phi$  or  $ct' \sinh \phi$ . Hence the real distance of  $B$  from the stationary origin is

$$x = x' \cosh \phi + ct' \sinh \phi.$$

Also the stationary observer knows that the clock at  $B$  is off from two causes, one its position, at a distance apparently  $x'$  from  $A$ , which sets it back really by

$$\frac{x'\beta^2}{v\sqrt{1-\beta^2}},$$

that is,

$$\frac{x' \sinh \phi}{c}.$$

The other cause is that the time read on the clock since the motion began is  $t'$ , but the real time as seen by the stationary observer, is  $t' \cosh \phi$ . Hence we have the equation

$$ct = x' \sinh \phi + ct' \cosh \phi.$$

From these equations the stationary observer could compute  $x'$ , which the moving observer would think was the distance of  $B$  from his moving origin, and the time  $t'$  on his moving clock. We have

$$\begin{aligned}x' &= x \cosh \phi - ct \sinh \phi, \\ct' &= -x \sinh \phi + ct \cosh \phi.\end{aligned}$$

These equations evidently are much like the first pair, and indeed we see that if we change

$$\begin{aligned}^2 \sinh \phi &= \beta / \sqrt{1-\beta^2}, \quad \cosh \phi = 1 / \sqrt{1-\beta^2}, \\ \sech \phi &= \sqrt{1-\beta^2}.\end{aligned}$$

the sign of  $\phi$ , that is, of  $\beta$ , or finally of  $v$ —which means that we imagine the moving observer to be at rest and the stationary observer to be relatively in motion—we have the second set. We would therefore expect that if we have two moving observers, with different velocities  $v$  and  $v'$ , we would find similar equations for their respective interpretations of each other's data as to distance and time. Thus indeed if

$$\begin{aligned}x &= x'' \cosh \psi + ct'' \sinh \psi, \\ct &= -x'' \sinh \psi + ct'' \cosh \psi,\end{aligned}$$

we find  $x'$  and  $ct'$  to be in terms of  $x''$  and  $ct''$ ,

$$\begin{aligned}x' &= x'' \cosh (\phi - \psi) - ct'' \sinh (\phi - \psi), \\ct' &= -x'' \sinh (\phi - \psi) + ct'' \cosh (\phi - \psi).\end{aligned}$$

We see at once from this that the relative velocity is not found by getting the difference of the velocities  $v$  and  $v'$ , but by getting the difference of  $\phi$  and  $\psi$ , that is, the relative velocity is

$$\tanh (\tanh^{-1} v - \tanh^{-1} v').$$

After this long preliminary we come to the paper before us which presents a full study of the geometrical representation of these facts, in a most elegant manner. The formulæ above are interpreted as representing a rotation in a four-dimensional space, but not a common space. The rotation in a common space would involve the  $\sqrt{-1}$ , and to preserve the real numbers as reals, the space chosen is a non-Euclidean space. After all, the difference is really this, that certain terms like *rotation*, *perpendicular*, etc., do not mean what they ordinarily do, but have meanings related to a given hyperbola, rather than to a given circle. Thus really *perpendicular lines* through the origin are conjugate diameters of a circle whose center is the origin. In the paper "*perpendicular*" still means *conjugate*, but as to a hyperbola and not a circle. This illustrates sufficiently the way in which the terms appear. Only a careful study of the paper itself can give a clear idea of the character of the presentation. The reader simply needs to be on the alert as to the geometrical meaning assigned here to familiar terms whose meaning has been altered.

The algebraical character of the paper needs a word. Instead of using a coordinate system and ordinary algebra, the authors develop a vector-algebra whose expressions represent directly the geometrical entities under discussion, and which in itself is unchanged by the changes in the axes of reference. This algebra is based upon the notions of Gibbs, and is the same as was developed by Lewis.<sup>1</sup> A rather complete development is given, including the analysis, or differential calculus of these vectors. In terms of the constancy of one of the vectors defined, the vector of extended momentum, the laws of conservation of mass, energy and momentum, are deduced, as well as fields of gravitational force and potential. It is not possible to enter into detail, as the technical character of the developments would demand a large amount of space to do them justice. However, any one desiring a complete and elegant account of the relativity theory, as it is seen in a geometric setting, will find it here. The laws of electromagnetism and mechanics are seen to be theorems in this geometry, which means of course that the representation as a non-Euclidean geometry of four dimensions is not only a fair representation, but is a complete representation of all the facts. It is not to be concluded, however, that it is the only representation; others have been suggested, which do not introduce the notion of a four-dimensional space in the sense it has above.<sup>2</sup> It should be pointed out, however, that the electrodynamic equations remain unaltered if we substitute a distance  $X$  for  $ct$  and at a time for  $x$  given by  $ct$ . So that if the universe is four-dimensional and we are moving with the velocity of light in one of the four directions of the fundamental axes, we can not tell which one it is, and indeed it makes no difference. Which means in the end (does it not?) that as we assumed in the beginning that the only thing we could measure absolutely is velocity, therefore, all distances must be expressed as velocities, that is, as times, or conversely, that time as we view

it is a distance. Indeed this is the fundamental assumption of the whole theory, that we may never know correctly absolute distance (if there be such a thing) nor absolute time, but we do know correctly absolute velocity.

The memoir is interesting also to mathematicians as a study of a particular non-Euclidean space and the corresponding vector algebra. It illustrates in a very happy way the great simplification introduced into a problem when we apply the proper symbolic analysis.

JAMES BYRNIE SHAW

*Introduction into Higher Mathematics for Scientists and Physicians.* By Dr. J. SALPETER. Jena, Verlag von Gustav Fischer. Pp. 336.

This book has the advantage—as compared with similar previous works—of being written in a very elementary and yet thoughtful fashion. The author has succeeded very well in explaining the principles of higher mathematics in an exceedingly plain way, yet so that he gives all the essential points. For instance, the first three chapters of the book (32 pages or about one tenth of the whole book) are exclusively devoted to a most detailed and elaborate explanation of the three fundamental conceptions upon which higher mathematics are based. These are: (1) the conception of the limiting value of an infinite series of figures; (2) the conception of a function; and (3) the conception of the derivation of a function. To explain the importance and real meaning of these fundamentals the author uses much space, and especially cites a great number of examples from different domains of natural science. In view of the purpose of this work, however, this explanation is not too long. After this introduction only, the technique of differentiating is discussed, also very clearly. Maxima and minima of functions, differential equations, integration, etc., are then explained thoroughly and clearly. At the end of each chapter numerical examples are given, as well as applications to scientific problems. The graphic method is extensively used. As a whole, the book can be recommended to such experimental investigators

<sup>1</sup> *Proc. Amer. Acad. Arts and Sci.*, 46: 163-182.

<sup>2</sup> *Timerding, Jahresb. d. Math. Ver.*, 21: 274-285, 1913.

who wish to make themselves acquainted with mathematical methods in a limited time. The importance of mathematics for all branches of natural science will certainly increase the more our knowledge progresses and increases in complexity, because it becomes more and more difficult to draw conclusions by non-mathematical reasoning. A book of such character as the one described can certainly therefore claim to be of great importance.

R. BEUTNER

ROCKEFELLER INSTITUTE

*Chloride of Lime in Sanitation.* By ALBERT H. HOOKER. First Edition. New York, John Wiley & Sons. 1913.

One of the most striking developments in the art of water purification during recent years has been the rapid increase in the use of chloride of lime as a disinfectant. It has been found that astonishing results may be obtained by the use of surprisingly small quantities of this substance. In clear water, such as that of the Great Lakes, the application of eight to ten pounds of this chemical to a million gallons of water is sufficient to destroy practically all of the bacteria. Larger amounts are required for waters which contain organic matter, in some instances nearly one hundred pounds per million gallons being used. Bleaching powder is also being used to some extent in the disinfection of sewage. Here, also, it has an important field of usefulness.

The rapidity with which the use of this substance has come into popular favor is indicated by the publication of the present work devoted exclusively to the use of chloride of lime in sanitation, and consisting chiefly of abstracts of articles published in various scientific journals. Four hundred of these articles are quoted and the essential points of each briefly stated. The author deserves credit for having brought these various papers together. It would be a tedious matter for any one interested in this topic to obtain so much information by his own search. Looking for omissions the reviewer finds that the compilation has been unusually well made.

The abstracts are prefaced with an interesting discussion of the general subject by the author, who gives first a history of the manufacture of chloride of lime and then an account of the method of its use in water purification and for other purposes of general disinfection. In this he is somewhat inclined to minimize the advantages of the use of liquid chlorine. He regards the action of bleaching powder as one of oxidation and does not believe that chlorine acts by itself as a disinfectant in any other way than by liberating nascent oxygen. Some may be inclined to question this. One of the most valuable sections of the book is that which gives directions for dissolving bleaching powder for its practical application. Comparatively little is said in regard to the corrosion of metals by the use of this chemical.

The book is well indexed and will prove an invaluable reference book to sanitary engineers.

GEORGE C. WHIPPLE

*The Plant Alkaloids.* By THOMAS ANDERSON HENRY, Superintendent of Laboratories. Scientific and Technical Department, Imperial Institute. Philadelphia, P. Blakiston's Son & Co. 1913.

So long as there is a science of botany, phytochemistry will constitute a perfectly justifiable phase of chemical thought and of chemical investigation. Though for a time, after Kekulé's enunciation of structural chemistry, phytochemistry was looked upon as being not fully up to date as compared with organic synthesis, it is again coming to its own. Since Emil Fischer has pointed out that some of the most interesting problems of organic chemistry are those that are intimately related to biochemistry, phytochemistry has once more become a respectable science even in the eyes of the synthetic chemist.

The present activity in this field is manifested not only by innumerable special researches, but by the rapid growth of book literature. Thus Czapek's "*Biochemie der Pflanzen*," Euler's "*Grundlagen und Ergebnisse der Pflanzenchemie*," and Wehmer's "*Pflanzenstoffe*," which have appeared within a short

period of six years, are indications of the attempts that are being made to bring together between the two covers of a book the modern knowledge in this field.

Most of the recent books, however, are content to present more detailed accounts of restricted phytochemical groups. Next to the literature on the volatile oils, on the fatty oils, and on the carbohydrates, which have received special consideration, no doubt, because of their industrial significance, the alkaloids have attracted considerable attention.

While the fatty oils and carbohydrates represent decidedly restricted groups of chemical compounds, the volatile oils and alkaloids represent much wider fields, chemically speaking. Biochemically, however, these two groups have been regarded as of much less importance than the carbohydrates and fatty oils. This has, however, not lessened their inherent chemical interest, which has always been appreciated. However, their physiological significance has also grown with our increasing chemical knowledge of the compounds of these two groups. Physiological interest is no longer restricted to skeleton-producing or energy-producing materials. It has broadened and by no means to the disadvantage of the science.

It has been said that modern pharmacology owes its existence to the discovery of the alkaloids. Hence one is not surprised to find the pharmacological aspect of the alkaloids receiving consideration even in a treatise that is predominantly chemical. For the same reason the pharmaceutical aspect of the subject has been given due consideration by the author of the book under consideration. Yet there is a purely phytochemical point of view that deserves more careful study than it has commonly received.

That the author of "The plant alkaloids" should follow conventional lines is possibly to be expected. That he himself does not find satisfaction in so doing becomes only too apparent from various statements that might be quoted from his introduction. From a purely chemical point of view, the alkaloids, like all other carbon compounds, should be classified in accordance with the definition that organic

chemistry is the chemistry of the hydrocarbons and their substitution products. Thus the conflicts and the irrationalities of a classification based on the so-called typical groups would be avoided. From a botanical point of view, the alkaloids of a family should be considered together, totally irrespective of the nuclei they are supposed to contain. Thus and thus only can genetic relationships be brought out satisfactorily. Such a treatment not only proves satisfactory in the consideration of a single phytochemical group, but it tends to destroy the arbitrary boundaries of these groups.

Nevertheless, we welcome the author's new treatise. It may be claimed that it would be better to revise one of the older texts on the subject. That such revision becomes necessary very often in these days of great research activity is apparent to all who have occasion to use these texts. However, if a new text brings the subject matter up to date, it, as a rule, not only fulfills this important requirement, it is also apt to do more. It usually introduces new points of view at least here and there. For this reason we often welcome a new text rather than the up-to-date revision of an older one.

E. K.

#### THE TEMPERATURE ASSIGNED BY LANGLEY TO THE MOON

IN his last publication on the lunar temperature,<sup>1</sup> Langley receded from his previous estimate "according to which the soil of an airless planet at the moon's distance

<sup>1</sup>"The Temperature of the Moon. From Researches made at the Allegheny Observatory." *National Academy of Sciences*, Vol. 4, Part 2, Third Memoir, 1889. Two editions of this work were printed. One is said to be "by S. P. Langley," the other "by S. P. Langley and F. W. Very." To prevent misapprehension, I will state that the memoir was the joint work of Mr. Langley and myself. A note written by Mr. Langley, explaining that my name had been omitted from a place on the title page with his own by an oversight noticed too late for correction, was, by some irony of fate, tacked on to the wrong edition, the one which did have my name on the title page.

would have a temperature not greatly above  $-225^{\circ}\text{C.}$ " On page 197 of that work, a summary of our observations in the lunar spectrum yields the result that "the most reliable spectrum comparisons with a blackened screen show an average 'effective lunar temperature' of  $+45^{\circ}\text{C.}$  near the time of full moon." Although the temperature which I had derived from the spectrum comparisons is thus cited, and is the only authoritative figure mentioned, a lingering predilection for his earlier value prevented more than a half-hearted acquiescence in my result on the part of Mr. Langley, who, as chief spokesman, said:<sup>3</sup>

Contrary to all previous expectations, [the extreme infra-red] nevertheless reaches us, thus bringing evidence of the partial transparency of our terrestrial atmosphere even to such rays as are emitted by the soil of our planet. It is probable, as remarked elsewhere, that even of the heat of arctic ice some minute portion escapes by direct radiation into space. If beyond this we can be said to be sure of anything, it is that the actual temperature of the lunar soil is far lower than it is believed to be; but the evidence does not warrant us in fixing its maximum temperature more nearly than to say it is little above  $0^{\circ}\text{Centigrade.}$

The last part of this extract refers to the belief that the moon's maximum temperature exceeds that of boiling water, a belief which rested on the opinion of Sir John Herschel and on some thermopile measures with a very large probable error which had been made of

<sup>3</sup>*Op. cit.*, p. 193. Langley's original statement in regard to the moon's temperature was founded on what he says ("Researches on Solar Heat," p. 213, 1884) concerning the earth's temperature in the absence of a selectively absorbing atmosphere, namely: "The temperature of the earth's surface is not due principally to this direct [solar] radiation, but to the quality of selective absorption in our atmosphere, without which the temperature of the soil in the tropics under a vertical sun would probably not rise above  $-200^{\circ}\text{C.}$ " This passage contains a mixture of truth and error. The radiation from a tropical surface at 300° Abs. is 285 times that of a similar surface at 73° Abs. The atmosphere has a protective influence, but not one as extraordinary as this. It must be remembered that Stefan's law was not yet fully accepted.

<sup>4</sup>*Op. cit.*, p. 193.

the total lunar radiation by Lord Rosse, and which, as is well known, had previously been our most reliable source of information.

I may perhaps be permitted to say that the preceding citation from our joint work did not represent the opinion of the junior contributor. Abbot and Fowle, referring to this memoir, speak of my "most recent revision of the evidence";<sup>4</sup> but this is a misapprehension, inasmuch as I have never revised the material contained in the above memoir. My later publications have been founded on new evidence which is entirely distinct.

Mr. Abbot also says in his work on "The Sun" (p. 311):

Upon the moon there is no atmosphere and by the observations of Lord Rosse, of Langley and of Very, the moon's sunlit surface falls from about the temperature of boiling water nearly to that of liquid air within the short duration of a total lunar eclipse.

But the preceding quotations prove that Langley never accepted the doctrine of the "hot moon" while he was director of Allegheny Observatory, and that even when pushed by the evidence, he hung back.

Professor W. H. Pickering in 1902 said:<sup>5</sup>

We do not certainly know the temperature of the moon's surface when exposed to a vertical sun; but according to Professor Langley, it can not be far from  $32^{\circ}\text{F.}$

N. S. Shaler, in a work published by the Smithsonian Institution in 1903 under Secretary Langley's supervision,<sup>6</sup> said:

The temperature of the moon has been made the matter of numerous experiments. These, for various reasons, have not proved very effective. The most trustworthy, the series undertaken by S. P. Langley, indicate that at no time does the heat attain to that of melting ice.

Consequently, up to 1903, Langley had not accepted the results which I published in 1898.

<sup>5</sup>*Annals of the Astrophysical Observatory of the Smithsonian Institution*, Vol. 2, p. 174.

<sup>6</sup>"Is the Moon a Dead Planet?" *The Century Magazine*, May, 1902, p. 91.

<sup>7</sup>"A Comparison of the Features of the Earth and Moon," *Smithsonian Contributions to Knowledge*, No. 1438. Part of Vol. 34, p. 6.

Although I have not heretofore attempted to revise the memoir on "The Temperature of the Moon," let me say here that the temperature for which I am responsible in that work (namely,  $+45^{\circ}$  C. on the average), and which is given, indeed, but in such a guarded way as to lose much of its force, is certainly too low. In proof of this, reference may be made to figures 11 and 12,<sup>7</sup> which show the position of the lunar image on the very wide slit which was necessary in order to obtain a readable galvanometer deflection in the almost evanescent lunar spectrum. It will be seen that at no time was the slit completely filled by the lunar image. There were always corners occupied by bits of sky, or by the unilluminated part of the moon, while the blackened screen containing boiling water always completely filled the slit aperture. Consequently, the lunar heat was underestimated. Moreover, the lunar radiation was an average pertaining to regions which include a wide range of temperatures, and necessarily fell much below the maximum radiation from the subsolar point.

In the description of the instrumental arrangements<sup>8</sup> we read:

'Care was taken that the lunar image formed by the condensing mirror, and having a diameter of 6.4 mm., should fall accurately upon the central portion of the slit, and thus only that portion is illuminated. In reducing the observations to a standard width of slit, the variation in this width from night to night having been considerable, the assumption is made that the amount of heat passing through the slit varies simply as the width, which is the same as to disregard the curvature of the upper and lower limbs of the lunar image, as well as the secondary effect of the variation of this lunar semi-diameter.

The inaccuracy of this disposition of lunar image and slit is obvious. The only excuse for neglecting it was that the condition of steadiness of our galvanometer at that time was not such as to call for any greater nicety in the other adjustments. No attempt was

made to assign a probable error to the numerical results. They were quantitative, but only roughly so. Hence it has seemed to me a waste of time to attempt to revise these measures. It would be better to repeat them with improved facilities.

Whether Secretary Langley ever accepted the results of the later measures which assign a temperature of  $454^{\circ}$  Abs. Cent.<sup>9</sup> to the lunar subsolar point is not known; but as he had already stepped up from  $-225^{\circ}$  C. to a temperature "a little above zero," let us hope that he may finally have been willing to go the rest of the way.

To those who find it difficult to accept a lunar surface temperature above that of boiling water, because of the low temperature at great elevations in the earth's atmosphere, where the rarefaction is still much less than on the moon, it may be pointed out that the insolation temperature attained by a planetary surface, after allowing for the variation in the intensity of sunshine, depends mainly on two factors: The duration of continuous insolation, and the absorbent power of the planetary atmosphere for return radiation from the planet's surface. The diminution of solar radiation in proportion to the inverse square of the sun's distance determines the available radiant energy, but the temperature acquired through exposure to sunshine depends to a still greater extent upon the nature of the atmospheric trap by which heat is captured. In this respect the greatest variety prevails among the planets of the solar system. The major planets possess denser and more highly absorbent atmospheres, capable of trapping greater and greater amounts of heat, as their distances from the sun increase. The evidences of heat, namely, strong aqueous absorption-bands in the spectrum, prevalence of cloud, and a vigorous circulation in the atmospheres of planets at so great a distance from the sun, may be explained on these principles, as is shown in my paper on "The Greenhouse Theory and Planetary Tempera-

<sup>7</sup> *Op. cit.*, p. 12.

<sup>8</sup> *Op. cit.*, p. 121.

<sup>9</sup> Frank W. Very, "The Probable Range of Temperature on the Moon," II., *Astrophysical Journal*, Vol. 8, p. 284, December, 1898.

tures,"<sup>10</sup> where, however, the application of the theory to Neptune is purely illustrative.

Mars has a rather rare atmosphere, but a climate of the continental type, giving it warm summers. Quantitative measures of the intensification of the aqueous absorption-bands in the spectrum of Mars<sup>11</sup> confirm the evidence of melting polar snows, and assure us that the summer temperature of Mars is considerably above the freezing point.

The earth, since it is nearer to the sun than Mars and has a denser atmosphere, is, on the whole, hotter than Mars. Terrestrial summer climates would be even hotter than they are, if it were not for the tempering effect of its oceans.

The air modifies surface temperatures both by its absorbent and its convective properties. All parts of the earth's insulated surface are cooled by contact with air in motion. This source of thermal depletion is very much smaller on the moon. On the other hand, the earth's temperature is very much increased by the absorbent action of its atmosphere on telluric radiation, an action which is probably very small on the moon, since its visible spectrum shows not the faintest atmospheric absorption. It is well known that the moon's atmosphere is excessively rarefied, yet a minute amount of some especially absorbent vapor might make a considerable difference in the night temperature, if the absorption-bands were of wave-lengths corresponding to low-temperature radiation. Spectrobolometric observations have not favored the supposition, but are hardly delicate enough to reject it absolutely. Without demanding any exact compensation in these two opposite tendencies, it is sufficient to see that they do oppose each other, and that the final controlling factor is duration of insolation. This is great enough on the moon to permit the formation of a steady subsurface thermal gradient, and the attainment of a maximum temperature de-

pending only on the absorptive coefficient of the surface and the solar constant of radiation. The fact to be emphasized is that no estimates of planetary temperatures are possible without considering the nature of the planetary atmospheres and the duration of insolation, and applying a knowledge of the principles of thermal conduction and of the "greenhouse" theory. But the moon is near enough to permit measurements of its radiant emission, in which the only hypothetical element remaining concerns the explanation of the observed facts. Since Abbot and Fowle, in connection with their objections to my value of the lunar temperature,<sup>12</sup> have referred favorably to the opinions of Dr. W. W. Coblentz, it may be well to point out a few statements by the latter writer which demand reconsideration. Dr. Coblentz in his paper, "Radiation from Selectively Reflecting Bodies,"<sup>13</sup> says:

The reflecting power of the moon for visible rays, according to Langley, is only 1/500,000 full sunlight. Assuming that at  $9\mu$  the reflecting power is, on the average, ten times that at 0.5 to  $4\mu$  (a low [sic] estimate), the value becomes 1/50,000.

Here, "reflecting power," or albedo, has been confused with the total amount of light reflected by the moon, expressed as a fraction of sunlight. I found that the average reflecting power of the moon for solar rays of every wave-length, both visible and invisible, was about 13 per cent.<sup>14</sup> Zöllner obtained, for visible rays, a lunar albedo of 17.4 per cent.<sup>15</sup>

<sup>12</sup> *Annals Smithsonian Observatory*, Vol. 2, p. 175.

<sup>13</sup> *Physical Review*, Vol. 24, p. 314, March, 1907.

<sup>14</sup> *Astrophysical Journal*, Vol. 8, p. 275, December, 1898.

<sup>15</sup> This includes a fraction due to specular reflection which causes the phase-curve for moonlight to differ from that for a diffuse reflector, as well as from the phase-curve for proper lunar radiation emitted from the heated surface (for which see Fig. 15 of my "Prize Essay on the Distribution of the Moon's Heat and its Variation with the Phase," and compare with Zöllner's curve in his "Photometrische Untersuchungen"). If the definition of albedo is restricted so as to include only diffuse luminous reflection, we have such values as the following: Wollaston, 0.12; Bond, 0.071;

<sup>10</sup> *Philosophical Magazine* (6), Vol. 16, p. 478, September, 1908.

<sup>11</sup> Frank W. Very, "Measurements of the Intensification of Aqueous Bands in the Spectrum of Mars," *Lowell Observatory Bulletin*, No. 36; and "New Measures of Martian Absorption Bands on Plate Rm 3076," *Ibid.*, No. 49.

Ten times these values would be a reflection of more than the whole and "a low estimate"!

To make my meaning entirely clear, let it be noted that the moon occupies on the average about 1/97,300 part of the hemisphere of the sky, and could send to the earth no more than this fraction of sunlight if it had an albedo of unity, or if it were a perfect diffuse reflector. With an albedo of 17.4 per cent., light from the full moon should be  $0.174/97,300 = 1/559,300$ . This is the fraction for which Coblenz adopts in round numbers 1/500,000. A smooth sphere having the property of specular reflection would yield a small star-like image of the sun of great brilliancy, the rest of the surface remaining dark. Nothing of the sort occurs, and the reflection is mainly diffuse; but the notable increase of brightness at, or near, full moon, and the somewhat greater brightness of the limb, as compared with the center, signifies that there is enough crystalline material in the rocky surface of the moon, and especially upon the cliffs which are presented favorably for observation along the lunar limb, to give an appreciable percentage of scattered specular reflections from innumerable crystalline facets. The distribution of such reflection may differ enough from that for a matte surface to account for the peculiarities of lunar reflection. Infra-red rays, on the whole, are less reflected than visible rays by the moon.

Dr. Coblenz finds for his hypothetical quartz moon an emissive power of 0.1 for a limited section of the spectrum near  $9\mu$ ; though his Fig. 5,<sup>16</sup> founded on the observations of Rosenthal, makes this fraction nearer 0.25. We may remark in passing that there are no common minerals with a relative emissivity as low as 0.1, even if we confine attention to this limited region of the spectrum, and that the most notable depression in the lunar spectrum at this point is also shown in the solar spectrum and is probably atmospheric. I speak of a "depression" in the Zöllner, 0.1195; W. H. Pickering, 0.0909. Compare Zöllner, "Berechnung der wahren und scheinbaren Albedo des Mondes," *op. cit.*, pp. 161, 162.

<sup>16</sup> *Op. cit.*, p. 317.

emission-curve, but the depression is only a minor feature in what is otherwise a maximum.

Describing his Fig. 7,<sup>17</sup> Coblenz says:

In Fig. 7, curves *b*, *c*, *d* show several of Langley's observed lunar radiation curves, and as a whole there is a close parallelism between the theoretical and the observed curve, especially at  $10.7\mu$ , where we have to consider only atmospheric absorption.<sup>18</sup>

There is a mistake here. Curve *d*, Fig. 7, is transferred from curve *c*, Fig. 6, which is derived in turn from the hypothetical emission curve with superposed atmospheric absorption. The supposed "close parallelism" vanishes when this mistake is corrected. The principal feature of the lunar curves is that they show a region of maximum radiation between 8 and  $10\mu$  (highest point at about  $8.3\mu$ ), where the hypothetical emission curve has a minimum. The mistake is indeed corrected a little farther on where we read (p. 318):

The computed emission curve is the most intense at  $10.2\mu$ , while the observed curve is the most intense at  $8.3\mu$ .

But here another error is introduced, for we are informed that

this is to be expected if the observed energy curve is the composite of the selectively emitted energy of the moon and the selectively reflected energy of the sun. The selectively reflected energy of the sun would, to a certain extent, fill up the minima in the lunar emission curve, and as far as our present knowledge goes would explain the observed curves *b*, *c*, *d* [a?], (Fig. 7), which lack a minimum at  $8.5\mu$ . As a whole, from whatever standpoint we view this matter, we come to the same conclusion, viz.: that in the region from 8 to  $10\mu$  the energy emitted from the moon consists of its own proper radiation and of reflected energy from the sun.

The explanation, unfortunately for this writer, does not explain, since, as I shall show, the reflected radiation can not possibly exceed about 1/3,000 of the emitted.

At this point in his argument, Dr. Coblenz

<sup>17</sup> *Op. cit.*, p. 319.

<sup>18</sup> *Op. cit.*, p. 318.

introduces the assumption that the absolute temperatures of sun and moon are  $5,900^{\circ}$  and  $350^{\circ}$ , and calculates by Planck's formula for the distribution of energy in the spectrum that the ratio of the radiations emitted at these temperatures by complete radiators is 1:0.00316.

This ratio of the emissive power [meaning by this the radiation from equal areas] of the moon to that of the sun [considering the latter to be a complete radiator but the former to have a relative emissivity of 0.1] will then be 0.000316, which is 16 times  $(0.000316 \div 0.00002)$  the reflected energy of the sun from the moon.<sup>19</sup>

But, as we have just seen, the derivation of the fraction 0.00002 is erroneous, the value assumed for the lunar emissivity is improbable even for a narrow region of the spectrum, and still more so for the entire spectrum, and the argument founded on the supposed lunar "reflected energy" is equally inadmissible, as we shall now see.

When it is remembered that the maximum deflection in the lunar spectrum (furnished by a rock-salt prism) at about wave-length  $1 \mu$  in the Allegheny measures was usually not over 10 divisions of a millimeter scale, and that the solar radiation at  $9 \mu$  is certainly *not more than a hundredth part of that at  $1 \mu$* , or 0.1 mm., the supposition by Coblentz that any appreciable part of the lunar spectrum at  $9 \mu$ , coming indiscriminately from all parts of the lunar surface, can be composed of *reflected* solar radiation, is seen to be preposterous.

The question of specular reflection does not enter here. Isothermal charts of the moon<sup>20</sup> show an entirely different distribution of total radiant energy on the moon's apparent disk from that of moonlight, but this distribution of total radiation is not much altered by the small amount of reflected light which it includes, and is altogether appropriate to that of the emission from a heated body having its highest temperature at the subsolar point.

<sup>19</sup> *Op. cit.*, p. 315.

<sup>20</sup> Frank W. Very, "Prize Essay on the Distribution of the Moon's Heat and its Variation with the Phase," Utrecht Society of Arts and Sciences, The Hague, 1891. Cf. Figs. 7 to 14.

Silicates have an emissive power not very different from 0.9 (nine times as great as this author assumes), or a reflecting power seldom much over 0.1. Throughout a considerable part of the region of proper lunar radiation, the reflected solar spectrum must have been smaller than 0.1, perhaps not more than 0.01 scale division, and it would have been absolutely unrecognizable. The actual deflections which reached upwards of 20 or 30 scale divisions in this part of the lunar spectrum were entirely due to emitted radiation; but the part of the lunar spectrum of wave-length shorter than  $4 \mu$  corresponded, both in the form of its energy-curve and in the fraction of its included energy, with the reflected solar radiation.

The supposed similarity between the reflection-curves obtained by Coblentz for some common silicates, and the lunar spectral energy-curve, a resemblance which is by no means conspicuous, is purely fortuitous. The lunar curve owes its shape to alteration by absorption in passing through the earth's atmosphere, and not to local abnormal reflection. The resemblance would have been even less approximate if Dr. Coblentz had drawn his theoretical radiation-curve for the temperature which I have indicated for the moon, which is *not* " $300^{\circ}$  abs.," notwithstanding that the reader of another work by the same writer, "Infra-red Reflection Spectra,"<sup>21</sup> might infer from a footnote that this temperature rests upon my measurements. The curves published in Fig. 90 of the same work and labeled "Reflection from Moon (Langley)," can not possibly have the assigned origin, as is evident from the preceding argument. In repeating this figure in the *Physical Review*,<sup>22</sup> the designation has been changed from "reflection" to a noncommittal "radiation," but the quotations cited show that the idea of reflection persists.

Dr. Coblentz also infers from observations

<sup>21</sup> William W. Coblentz, "Investigations of Infra-red Spectra," Part 4, Appendix 1, p. 114. Carnegie Institution of Washington, 1906.

<sup>22</sup> Vol. 24, Fig. 3, p. 312.

measured in the image of the eclipsed moon that the radiation is reflected and not radiated; but the curves which he has drawn<sup>23</sup> for the eclipse of September 23, 1885, as measured at Allegheny by Mr. J. E. Keeler and myself, are incorrect, since the heat at no time vanished, although it diminished continually until the end of totality; and in other eclipses which I have observed, the heat measured in the image of the eclipsed moon has never been less than 1 per cent. of its value before eclipse, while the diminution of the light is sometimes a millionfold greater; that is to say, there is simply no comparison between the reflected radiation and that emitted by the heated lunar surface during totality. The radiation enormously exceeds the reflection at that time.<sup>24</sup>

I am at a loss to know the source of the statement by Dr. Coblenz that "at the last quarter the heat of the moon is certainly not less than at the full."<sup>25</sup> This statement is totally at variance with all published observations.

One other misapprehension needs to be corrected. It is found in the work on "The Moon" by Professor W. H. Pickering.<sup>26</sup> Professor Pickering says (p. 20):

The most satisfactory test hitherto made seems to be that of Professor Very (*Astrophysical Journal*, 1898, VIII., p. 266), who compared the amount of heat received from the moon by a bolometer with that received from an equal angular area of sunlit melting snow. The heat was next in each case allowed to pass through a piece of clear glass before reaching the bolometer. The glass allows nearly all the reflected heat to pass, but absorbs that radiated by the body itself. The total radiation in the two cases was about the same, but while the reflected heat was much greater from the snow than from the moon, it was found that the radiated heat was much greater from the moon than from the snow. This means that while the snow is the better reflector, as,

<sup>23</sup> *Physical Review*, Vol. 24, Fig. 1, p. 310.

<sup>24</sup> Compare Frank W. Very, "The Temperature of the Moon," *Astrophysical Journal*, Vol. 24, p. 354, December, 1906.

<sup>25</sup> Carnegie Institution publication, p. 112.

<sup>26</sup> Published by John Murray, London, 1904.

indeed, we can see by inspection, the moon is the hotter body. The observation is so direct and simple that it seems impossible to deny the accuracy of the conclusion, but of course it gives us no clue as to what the actual temperature is.

The recognition of the value of this particular observation is all that could be asked, but the really convincing and conclusive experiments with radiating heated minerals, which were performed under identical experimental conditions, and which do give us a "clue as to what the actual temperature is," are not even mentioned in this work, and have been strangely underrated elsewhere.

Professor Pickering goes on to say:

It would be interesting to repeat Professor Very's observation, comparing the radiation from the surface of the moon with that from the surface of rock illuminated by the sun at temperatures ranging from the melting point of snow to the highest attained by rocks on the earth's surface when exposed to a nearly vertical sun.

Experiments somewhat resembling those suggested, but more instructive, had already been performed.

Another instance of the same misapprehension follows. Abbot and Fowle say:

Coblenz has lately shown that some of the materials likely to be prevalent on the moon's surface are very poor radiators at such temperatures as these, and this would tend to explain why Very has found a temperature so much higher than that of a "black body" under similar conditions.

They also remark:

We do not know what its surface is composed of, and therefore have no means of discovering the relations which connect the lunar temperature and radiation.<sup>27</sup>

The opinion that "the moon is probably a very bad radiator" is also reiterated by these authors in a recent article,<sup>28</sup> where are some personalities to which I need make no further allusion, as they only obscure the real question.

<sup>27</sup> *Annals Smithsonian Observatory*, Vol. 2, p. 174.

<sup>28</sup> *Astrophysical Journal*, Vol. 25, p. 95, March, 1912.

The language of these quotations implies that I have not considered the radiating power of the actual lunar substance, but have assumed an ideal moon; whereas the truth is that extensive observations were made on the radiations from heated silicates and other substances of which the moon's surface is liable to be composed, and comparisons were instituted with these, and not with an ideal radiator, before reaching a final conclusion. The result of this comparison of the radiant behavior of various materials is important, since I find<sup>29</sup> that, given a sufficient duration of insolation to enable a steady state to be reached, there is not much difference in the emission from various materials. Thus a very poor radiator, such as rock salt, radiates from a great depth of its interior substance, and the summation of radiation from many interior layers compensates for the small emission from any one layer. Hence it is not correct in such cases to state emissivity as a surface function. The complete statement of emissivity must be a volumetric one and must include the subsurface thermal gradient.

Ferrel showed on theoretical grounds that the law connecting temperature and radiation for the moon may be expressed as an equation of condition, where, if the coefficients of radiation and absorption of the same substance are always equal, it makes no difference what the substances are; all will eventually reach the same temperature. Some exception to the theory must be made for such substances as ice which are kept cool by melting and evaporation in sunshine. In his actual illustration, Ferrel used the law of Dulong and Petit, but any other formula may be substituted as far as the principle in question is concerned. The important point is that

the same results would be obtained sensibly with any ordinary conductivity for heat if the same side of the moon were permanently exposed to the sun, for the temperature gradient by which the heat would be conducted inward would soon be-

come so small, in this case, that the rate by which heat would be conducted inward would be insensible, as in the case in which heat is conducted outward from the interior of the earth.<sup>30</sup>

In a different category from the books and articles already cited come such works as that by Fauth.<sup>31</sup> A footnote on page 26 of this book refers to my writings on the moon, but the author does not appear to have read them carefully. On page 139 he says:

Lord Rosse was enabled by his measurements to appreciate the differences in temperature on the moon's surface during full radiation and by night, and found them to be over 300° C. But the temperature can not be determined with any accuracy. Lord Rosse's results have often been questioned, but they are supported by the recent investigations of Very. Very believes that at the moon's equator, when the sun is at its highest, the ground increases its temperature by more than 100° C. (which would be -173° C.).

This is pretty nearly a hopeless case. I am sure that neither Lord Rosse nor I could recognize our own work in the conclusions attributed to us, where absolute temperatures and temperatures on the centigrade scale are mixed up indiscriminately, in spite of carefully guarded language in the original sources, and where the opinion is hazarded that the *maria* are frozen oceans—a supposition which is completely overthrown by the thermal measures.

The selection of these quotations for special mention does not imply that there are not others equally objectionable in the literature of the subject.

My chief reason for wishing to call attention to the imperfect conceptions of one whose splendid contributions to science condone all minor imperfections is because Langley's early and gradually changing opinions on the subject of lunar temperature still act as a barrier against the acceptance of conclusions which are founded on reliable observations. This will be quite evident from the passages

<sup>29</sup> William Ferrel, *SCIENCE*, Vol. 6, p. 542.

<sup>30</sup> "The Probable Range of Temperature on the Moon," I., *Astrophysical Journal*, Vol. 8, pp. 199-217, November, 1898.

<sup>31</sup> "The Moon in Modern Astronomy," by Ph. Fauth, with an introduction by J. E. Gore, F.R.A.S.

cited from the treatises of Shaler and Pickering.

In conclusion, let me remark that even though we can not go to the moon to see for ourselves what its temperature may be, or whether gravitation acts there as here, or what may be the power of the sun's unabsorbed radiation, we are gifted with reason and can form for ourselves just conclusions from observed facts. Otherwise all astrophysics would be impossible.

FRANK W. VERY

WESTWOOD ASTROPHYSICAL OBSERVATORY,

May, 1912

#### THE ORE DEPOSITS OF WESTERN UNITED STATES

AMONGST the valuable publications issued by the United States Geological Survey is Mr. James M. Hill's Bulletin 507 with the misleading title "The Mining Districts of the Western United States," as it deals solely with the metalliferous mining districts. These districts are grouped and numbered in each one of the 13 states considered, and their distribution is shown upon 14 maps. The text gives for each district its chief rocks and metalliferous products, the publications of the Survey relating to each one, and the distance and direction of the nearest railroad station, etc. A full index of all the districts mentioned concludes the work, which should be in the hands of every one interested in the ore deposits of the west.

To the general student of metalliferous deposits probably the most instructive portion of the bulletin will be the "Geologic Introduction," by Professor Waldemar Lindgren, late chief geologist of the Survey, present head of the Department of Geology of the Massachusetts Institute of Technology, and one of our foremost mining geologists.

The evidences of the mineral wealth of the Cordillera are found extending territorially from the Pacific shore of United States eastward to western Texas and Oklahoma, and geologically from the Pre-Cambrian to the Recent.

Since the deposition of ores is due to geo-

logic agencies, it is pointed out that in the Cordilleran region, where the rocks are horizontal and undisturbed, the ore deposits are missing or rare and poor. Again, while the metallites occur mostly in the mountain ranges, yet many, even of the highest, are barren; showing that without other conditions, uplift, faulting, and crushing of the rocks, and the circulation of water through them does not always produce ore deposits.

Characteristic important deposits are where Paleozoic sediments have been traversed by moderate-sized eruptive masses of Cretaceous or Tertiary age, the ores apparently being deposited shortly after the intrusion. A less common but often rich deposit is found in Tertiary andesitic and rhyolitic flows.

All these deposits are believed to have been formed by water solutions—largely in fissure veins, chambers, and impregnations. The ores, except gold and its tellurides, were apparently originally deposited as sulphides of lead, iron, zinc, etc., or oxides of iron; but down to or below the permanent water level, which varies from a few hundred to 2,200 feet, these sulphides have been oxidized to cerussite, hematite, calamine, etc. Just below the oxidized zone occur secondary sulphides, like chalcocite and silver-bearing minerals, concentrated by the percolating waters, often into bodies of great richness.

Professor Lindgren gives under each state a more detailed summary, but space does not allow us to continue further, and any one interested can procure a copy by writing to the director of the Geological Survey at Washington.

Without intending to be captious it is suggested that in future editions the term "ores" should be used for "metallic ores" (see pp. 7-9), because there are no ores that are not metalliferous. In the same way "mineral deposits" ought not to be used for metallites or metalliferous deposits when the author intends to exclude the memetallites or non-metalliferous deposits (see pp. 5-9).

M. E. WADSWORTH

UNIVERSITY OF PITTSBURGH

## SOCIETIES AND ACADEMIES

NEW YORK ACADEMY OF SCIENCES  
SECTION OF GEOLOGY AND MINERALOGY

ON December 2, 1912, Professor J. Edmund Woodman, chairman of the section, called the meeting to order at 8:25 P.M., in the west hall of the American Museum of Natural History.

No regular business was transacted, but the whole time given over to a lecture on "The Seismograph and What it Teaches," by Professor Harry Fielding Reid. Professor Reid explained the principles of construction and some of the differences in seismographs, using an extensive assortment of lantern views. The lecture was very instructive, and aroused especial interest because of the recent installation by the New York Academy of Sciences of a new seismograph in the American Museum of Natural History, where the section holds its meetings. At the close of the lecture opportunity was given to inspect the new instrument. About 150 members and visitors were present.

CHARLES P. BERKEY,  
*Secretary of Section*

ON January 6, 1913, immediately following the adjournment of the regular business meeting of the New York Academy of Sciences, Professor J. Edmund Woodman, chairman of the section, called the meeting to order in the usual meeting place in the American Museum of Natural History, at 8:25 P.M.

Professor D. W. Johnson delivered a paper on "The Shoreline of Cascumpeque Harbor, Prince Edward Island." After explaining with the aid of blackboard maps and sketches the criteria for distinguishing between real and apparent oscillations of shorelines, Professor Johnson further illustrated the discussion with lantern views, amplified where necessary by means of diagrams thrown on the screen. He concluded that the area under discussion is probably the best example of features normally produced by subsidence of a maturely dissected plain to be found on our Atlantic seaboard. He finds no evidence, however, that indicates subsidence in geologically recent times—that is, within the last 2,000 years. In the questionnaire following, the speaker presented still other evidences strengthening his conclusions as to the duration of stable conditions, and made brief references to other localities along the Atlantic coastline of North America.

The program was concluded by brief notices of important papers given at the meeting of the Geological Society of America, at New Haven,

Conn., December 28–31, 1912. Ten minutes were devoted to each of the groups, paleontology, economic geology and petrology, by Professor A. W. Grabau, Professor James F. Kemp and Charles T. Kirk, respectively. The meeting, though technical, was attended by some fifty persons.

CHARLES T. KIRK,  
*Secretary of Section*

ON February 3, 1913, the chairman of the section, Professor J. Edmund Woodman, called the meeting to order in the west lecture room of the American Museum of Natural History, at 8:30 P.M., and introduced Mr. F. H. Newell, director of the U. S. Reclamation Service. Under the title of "Home-making in the Arid West" the speaker delivered an extremely interesting and instructive lecture on the problems of irrigation in our arid and semi-arid regions. He showed how the United States irrigation engineers must be able to handle a manifold situation. In many instances the determination of flood water possibilities, the areal survey of the project, and the installation of the dam are coupled with such other considerations as soil surveys, building and running a cement plant, constructing and managing a railroad for passenger- as well as freight-traffic, generating and subletting electric power from the flood water spilling over the dams, providing for workmen in isolated settlements—even to furnishing them amusements in the way of motion picture shows—dealing with Indian tribes to the extent of inducing the men to work; all these and other institutions and functions being owned and controlled by the Reclamation Service of the United States government.

To carry out the various projects requires the expenditure of some twelve million dollars annually, or about a million a month. When the score or more of projects are all completed, homes on the farms and in the villages of the arid west will be provided for more than two million families.

The fallacy of dry farming was clearly shown by the loss of about one crop in three through such practise.

The lecture was splendidly illustrated with polychrome slides of very characteristic western views. Owing to unpleasant weather, but 75 persons attended. The audience was further entertained by Director Newell's informal replies to questions from members and visitors after the formal presentation of the subject.

## Important New Macmillan Publications

### The Depths of the Ocean

By Sir JOHN MURRAY, K.C.B., F.R.S., etc., of the "Challenger" Expedition, and Dr. JOHAN HJØRT, Director of the Norwegian Fisheries. With contributions from Professors A. Appelhof, H. H. Gran, and Dr. B. Helland-Hansen.

A general account of the modern Science of Oceanography based largely on the scientific researches of the Norwegian steamer "Michael Sars" in the North Atlantic during 1910. Handsomely illustrated with photographs, plates, maps, charts of the ocean depths, etc. *Cloth, 8vo, \$7.50 net; postpaid, \$7.84.*

### Meteorology

By W. I. MILHAM, Professor of Astronomy in Williams College; Author of "How to Identify the Stars," etc. This volume explains in clear, untechnical language the entire mechanism controlling our ever changing weather, and is of especial value as a text-book in meteorological courses. *Cloth, 8vo, \$4.50; postpaid, \$4.73.*

### Earth Features and Their Meaning

By WILLIAM HERBERT HOBBS, Professor of Geology in the University of Michigan; Author of "Characteristics of Existing Glaciers," etc. Places before the general reader and student the geological meaning of landscapes, with an unusual number of appropriate illustrations. *Cloth, \$3.00 net; postpaid, \$3.24.*

By the same Author.

### Characteristics of Existing Glaciers

Illustrated by 34 plates and 140 text-figures. *Cloth, 8vo, \$3.25 net; postpaid, \$3.47.*

### College Zoology

By ROBERT W. HEGNER, Ph.D., Assistant Professor of Zoology in the University of Michigan. A text for students in universities and colleges or for the general reader who wishes to gain a more comprehensive view of the animal world. *Illustrated. Cloth, 12mo, \$2.60 net; postpaid, \$2.84.*

### Methods of Organic Analysis

By HENRY C. SHERMAN, Ph.D., Professor of Food Chemistry in Columbia University; Author of "Chemistry of Food and Nutrition." The second edition, rewritten and enlarged. *Illustrated. Cloth, 8vo, \$2.40 net; postpaid, \$2.60.*

### The Calculus

By ELLERY WILLIAM DAVIS, Professor of Mathematics, University of Nebraska. An important work presenting as many and as varied applications of the Calculus as it is possible to do without abandoning an orderly presentation of principles. *Cloth, 12mo, \$2.00 net; postpaid, \$2.18.*

### A Treatise On Hydraulics

By WILLIAM CAWTHORNE UNWIN, LL.D., F.R.S., Emeritus Professor of the City and Guilds (Engineering) College, M. Inst. Civil Engineers, Hon. M. Inst. of Mechanical Engineers, Foreign Hon. M. Am. Academy of Arts and Sciences, M. Inst. of Electrical Engineers. *Cloth, 8vo, \$4.25 net; postpaid, \$4.45.*

## Marine Biological Laboratory WOODS HOLE, MASS.

### INVESTIGATION

JUNE 1 TO OCTOBER 1

Facilities for research in Zoology, Embryology, Physiology and Botany. Fifty-five private laboratories, \$100 each for the season. Twenty tables are available for beginners in research who desire to work under the direction of members of the staff. The fee for such a table is \$50.00.

### INSTRUCTION

JULY 2 TO AUGUST 12,  
1913

Courses of laboratory instruction with lectures are offered in Invertebrate Zoology, Embryology, Physiology, Morphology and Taxonomy of the Algae, Physiology and Ecology of Marine Strand and Bog Vegetation. Each course requires the full time of the student. Fee, \$50.00. A lecture course on the Philosophical Aspects of Biology and Allied Sciences is also offered.

### SUPPLY DEPARTMENT

OPEN THE ENTIRE  
YEAR

Animals and plants, preserved, living, and in embryonic stages. Preserved material of all types of animals and of Algae, Fungi, Liverworts and Mosses furnished for classwork, or for the museum. Living material furnished in season as ordered. Price lists of Zoological and Botanical material sent on application. State which is desired. For price lists and all information regarding material, address

GEO. M. GRAY, Curator, Woods Hole, Mass.

The annual announcement will be sent on application to The Director, Marine Biological Laboratory, Woods Hole, Mass.

## University Control

By J. McKEEN CATTELL, Professor of Psychology in Columbia University

Together with a series of Two Hundred and Ninety-nine Unsigned Letters by Leading Men of Science holding Academic Positions and Articles by JOSEPH JASTROW, GEORGE T. LADD, JOHN J. STEVENSON, J. E. CREIGHTON, J. McKEEN CATTELL, GEORGE M. STRATTON, STEWART PATON, JOHN JAY CHAPMAN, JAMES P. MUNROE and JACOB GOULD SCHURMAN.

A great variety of questions concerning general university administration are dealt with in an original and helpful way.—*Nature*.

These quotations and examples are taken from Professor Cattell's informed and thorough discussion of the subject of university control, a subject upon which he has had much to say of late, finding occasion for caustic criticism of existing American conditions, and standing as the champion of an academic democracy and a teaching profession upon which a man may enter without forfeiting his self-respect.—*The Dial*.

Sentences and paragraphs that betoken the expert, highly-trained mind, the suggestions that come to refresh and tell us that a new day is about to dawn in educational writing.—*The Boston Evening Transcript*.

## SCIENCE AND EDUCATION

A series of volumes for the promotion of scientific research and educational progress

VOLUME I. The Foundations of Science. By H. POINCARÉ. Containing the authorized English translation by GEORGE BRUCE HALSTED of "Science and Hypothesis," "The Value of Science," and "Science and Method." In Press.

VOLUME II. Medical Research and Education. By RICHARD M. PEARCE, WILLIAM H. WELCH, W. H. HOWELL, FRANKLIN P. MALL, LEWELLYS F. BARKER, CHARLES S. MINOT, W. B. CANNON, W. T. COUNCILMAN, THEOBALD SMITH, G. N. STEWART, C. M. JACKSON, E. P. LYON, JAMES B. HERRICK, JOHN M. DODSON, C. R. BARDEEN, W. OPHÜLS, S. J. MELTZER, JAMES EWING, W. W. KEEN, HENRY H. DONALDSON, CHRISTIAN A. HERTER, and HENRY P. BOWDITCH. In Press.

VOLUME III. University Control. Now Ready. Pages x+484. Price, \$3.00 net.

MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

## THE PHYSICO-CHEMICAL CONDITIONS OF ANESTHETIC ACTION<sup>1</sup>

UNDER certain well-defined artificial conditions, as well as under some that are normal, the living system—organism, tissue or cell—becomes temporarily inactive and irresponsive to stimuli. When such an artificially induced state of inhibition is well marked and lasting it is called anesthesia, or in a somewhat more restricted sense, narcosis. This condition may last for hours or even days, but apparently not indefinitely; and when it passes off the normal vital activities and properties return unimpaired. This apparently complete reversibility is one of the most remarkable features of anesthesia, and distinguishes it from death—a perhaps related but characteristically irreversible change. The terms “anesthesia” and “narcosis” are somewhat differently applied, although they have the same essential significance; the former relates to any temporarily insensitive condition, however produced, while “narcosis” usually means an anesthesia produced by chemical substances. I shall use the term anesthesia throughout the present address to designate any temporary or reversible lowering or loss of the normal vital responsiveness, or of the normal automatic vital activity, under the influence of certain artificial substances or conditions. Anesthesia, as thus defined, may be exhibited by the most various organisms and cells, if not by all. It is fully as characteristic of plant cells as of animal cells, although its manifestations may be less obvious and striking

<sup>1</sup>Lecture given before the Chemical Society of Washington, April 11, 1913.

in the former group of organisms. In its most familiar aspect the complete organism, *e. g.*, a man, or an isolated living tissue, as a nerve or muscle, fails during anesthesia to show any response to a stimulus which normally excites it strongly. In other words, the capability of responding to stimuli—what we call “irritability”—is in anesthesia diminished or lost. When the condition passes off the normal responsiveness returns unimpaired. Thus a muscle exposed to ether vapor soon ceases to contract on stimulation; under the same conditions a nerve ceases to conduct; in motile plants like sensitive plants the characteristic osmotic motor mechanisms cease to act. Automatic activities like amoeboid movement, ciliary movement, protoplasmic flowing, cell division, and growth may also be brought temporarily to a rest by anesthetics. Claude Bernard showed long ago that seedlings ceased growth in an ether-impregnated atmosphere, and resumed it when the ether was removed. Fertilized egg-cells cease to divide in the presence of an anesthetic in appropriate concentration, although they remain living and proceed with cell-division and development when the anesthetic is removed. Other less evident cell-processes, including metabolism, are similarly affected; the rate of oxidation is usually slowed during anesthesia, though there are exceptions to this rule.

It should be remembered that such decrease of the vital activity or responsiveness is not a solely artificial phenomenon. Conditions physiologically resembling anesthesia occur normally in the life of many organisms; sleep is in fact a kind of physiological regularly recurring narcosis due apparently to accumulation of certain metabolic products in the blood or tissues. Again, all irritable tissues lose their responsiveness for a brief period following excitation; this is the so-called “refractory

period,” which has been compared with narcosis by some physiologists. The resemblance in this case is probably superficial; but I call attention to this phenomenon in order to show once more that temporary loss of irritability may occur under normal or physiological conditions as well as under artificial. There are also noteworthy resemblances between narcosis and fatigue. Thus the degree of irritability of a tissue may vary within a wide range under normal as well as artificial conditions.

We shall first inquire under what general conditions irritable tissues undergo reversible decrease or loss of irritability. These conditions are various. One of them is cold. The living system operates within a narrow range of temperature. Most irritable tissues or cells become less responsive or lose irritability as the temperature approaches zero. In a muscle or nerve of a cold-blooded animal the ability to respond to stimulation is not necessarily decreased by a moderate reduction of temperature—in fact, slight cooling may increase the irritability of nerve; the tissue responds in the typical manner, but the *rate* of the response—as indicated by the duration of the single contraction in muscle or of the electrical variation in nerve—is always decreased, typically to a degree corresponding to the usual temperature-coefficient of chemical reaction-velocity. In the neighborhood of zero stronger stimuli becomes necessary to elicit a response, and eventually none may appear. Different organisms vary in these respects. In some animals, as tropical medusae, irritability is abolished or greatly lowered at a temperature considerably above zero. The same is true of warm-blooded animals. On return to normal temperature irritability is restored.

Another condition producing effects resembling anesthesia is lack of oxygen. This

retards or arrests activity in many cases; *e. g.*, the nerve cells of vertebrates are very susceptible to lack of oxygen; nerve trunks, on the other hand, are relatively insusceptible. Cell-division—*e. g.*, in developing egg-cells—usually ceases if the oxygen supply is insufficient. Contractile activities are decreased or abolished. Many organisms, however, show only slight immediate effects; this is true of many Protozoa; Vorticellæ, for instance, remain contractile for some time after simple removal of oxygen from the medium, although they are at once paralyzed by anesthetics. Such facts oppose the view held by Verworn and others, that the anesthetic acts primarily on the oxidative mechanism of the cell. It is true that the rate of oxidations in active tissues is lowered during anesthesia, but this effect is rather a consequence than a cause of the lessened activity. Obviously wherever free oxygen is necessary to the normal activities of a tissue its withdrawal will arrest those activities. But the effects produced by lack of oxygen are not to be identified with anesthesia because of such incidental resemblances.

There are also a number of physical conditions that may deprive a cell temporarily of irritability. Thus mechanical shock may have this effect, which, however, is probably to be regarded as essentially a consequence of over-stimulation, causing abnormal prolongation of the refractory period.<sup>2</sup> The same is probably true of the insensibility produced by strong electrical currents. Under certain conditions, however, the electric current may produce effects closely resembling typical anesthesia. This occurs when a weak constant current is passed through an irritable tissue like muscle or nerve; during the flow of the

current the irritability of the tissue is modified in the neighborhood of the two electrodes, being heightened at the cathode and lowered at the anode; and in this latter region the nerve may become completely insensitive to stimuli that ordinarily cause strong excitation. The inexcitable state thus produced is called "anelectrotonus"; it is in reality a form of local anesthesia, and as such has been employed for the alleviation of pain in sciatica and similar conditions. Muscle is affected in a similar manner; the frog's heart may thus be rendered locally incapable of contraction, as in the simple class-experiment familiar to all physiologists. This action of the current probably depends on its altering the electrical polarization normal to the membranes of the irritable elements—only in a direction the inverse of that causing stimulation.<sup>3</sup> There is much evidence that the state of polarization of the semipermeable membranes bounding the irritable elements is an important factor in determining the degree of responsiveness to stimulation; the facts of electrotonus indicate that by altering the polarization by an external current the irritability of the tissue may be changed in the direction either of increase or of decrease.

Irritability may, however, be more readily modified by the use of chemical substances than by any other means, and, as is well known, many such substances are in daily use in medical and surgical practise for procuring local or general insensibility to pain—hence the application of the name "anesthetic" to the large class of substances possessing this property. When we inquire into the chemical nature of such substances we find that anesthetic property is confined to no special class, but is ex-

<sup>2</sup> This apparently corresponds to the period of increased permeability and depolarization accompanying stimulation.

<sup>3</sup> *I. e.*, reinforcing instead of diminishing the normal or physiological polarization of the membranes.

hibited by substances of the most diverse chemical character. Acids in low concentration depress the irritability of many tissues; in some cases alkali has this effect; gases like carbon dioxide and nitrous oxide have marked anesthetic action; solutions of magnesium, calcium and strontium salts cause local anesthesia in frog's muscle and nerve; pure solutions of sugar and other indifferent non-electrolytes have similar effects; in these tissues irritability depends on the presence of certain electrolytes, especially sodium salts, in the media and returns on replacing the tissues in solutions containing these salts. But the most significant relationships are seen in the case of the large class of substances, differing widely in chemical constitution and properties, which possess in common the physical property of dissolving fats or of dissolving in fats. These substances include the majority of the anesthetics in common use, as ether, chloroform, ethyl chloride, urethane, etc. The connection between fat-dissolving power and anesthetic property was in fact early recognized—first by Bibra and Harless in 1847; and this relationship is of great physiological significance, since it indicates that the anesthetic is selective in its action on the cell constituents, and produces its effects by changing the state of fatty or fat-like substances in protoplasm. It indicates further that the state of these substances determines the degree of irritability of the cell. All cells, so far as known, contain such substances; they are the so-called "lipoids" which include lecithin and cholesterin, and various other ether-soluble compounds of usually complex constitution. Historically these substances were first grouped into a class simply on account of their fat-like solubilities, so that they form, chemically speaking, a somewhat heterogeneous group, some members of which, as cholesterin, are not

fats in any sense. Others, as lecithin, are more closely related to the fats proper. They appear to be invariable constituents of protoplasm—a fact which in itself is not surprising in view of the amino-acid constitution of proteins: since proteins are largely derivatives or condensation-complexes of amino-fatty acids, fat-like substances might be expected to appear in cells during metabolism. It is clear, however, that these substances are not mere by-products of protein metabolism, or reserve material like fats, but play a fundamental rôle in cell-processes; the profound physiological effects produced by all lipid-solvent substances are a sufficient proof of this, although regarding the precise nature of this rôle we know little as yet. In some intimate way the lipoids appear to be essential to the irritability of the cell, and altering their state causes corresponding changes of irritability.

About fifteen years ago Overton and Hans Meyer investigated the relation between the lipid-solvent power of a large number of organic anesthetics and the intensity of their narcotic action, and reached independently the conclusion that the chief factor determining this action was the value of the partition-ratio of the anesthetic between water and a typical lipid like lecithin. That is, for any series of lipid-soluble compounds the narcotic action increases as the lipid-solubility increases and the water-solubility decreases. These two solubilities usually show an inverse relation to each other. Now, the view that this form of anesthetic action depends essentially upon a modification of the cell-lipoids—which was put forward simultaneously and independently by Overton and Meyer—is undoubtedly well founded, and is accepted by most physiologists, even although in the absence of any definite and final knowledge of the physiological rôle

of these cell-constituents it is far from being a complete theory of anesthesia. Such a theory would evidently involve a complete theory of stimulation, and this can hardly be said to exist as yet. It is, however, possible, I believe, to gain further insight into the nature of anesthetic action by combining the results of these and similar experimental studies of anesthesia with the results of certain more recent studies of the nature and conditions of the process of normal stimulation. It is necessary to form some clear conception of the nature of the changes involved in stimulation before we can profitably consider the question of just how the stimulation-process is modified by the presence of the anesthetic.

Before considering in more detail the mechanism of stimulation and of its modification by anesthetics, let us first consider briefly the nature of the physico-chemical constitution of the living cell, as more recent research has led us to conceive of it. This is a subject which is not easy to summarize, and on which much light remains to be thrown. It is clear, however, that the living protoplasm is not a homogeneous solution, but is a "polyphasic system"; *i. e.*, a mixture consisting of various substances and solutions which are only partly miscible with one another, and are thus inter-related like the different phases of an emulsion or similar system. These several phases, which are partly solid, partly liquid, appear in each living cell to have a constant and definite arrangement, whose exact nature varies characteristically from cell to cell. There appears typically to be a solid or semi-solid structural substratum consisting of colloidal material, most of which is in a water-swollen or hydrated state; in addition to this more fixed and permanent part of the cell-organization, numerous simpler substances are present—sugars, salts, amino-acids and others—largely in a

state of simple aqueous solution, but probably partly adsorbed at the surfaces of the colloidal phases. There is evidence that it is by the oxidation of certain of these substances, especially sugar, rather than of the colloidal material, that most of the energy manifested in the cell-processes is set free. The colloidal substratum furnishes the conditions under which the energy-yielding oxidations and other metabolic changes take place, and apparently determines their course, character and velocity. The solid colloidal material of the cell may in one sense be considered as by-product of the metabolic activities of the protoplasm; it appears, once formed, to undergo itself relatively slight change, but to influence profoundly, by its presence and arrangement, the character of cell-metabolism.<sup>4</sup> The colloids are of varied chemical nature; they are chiefly proteins and lipoids, and it is to be noted that they are built up by various forms of molecular union and polymerization from relatively simple substances furnished by the environment. This is true not only of plants, but also of the individual cells of higher animals, where the material which goes to form proteins reaches the cell in the form of amino-acids, or of simple polypeptides.<sup>5</sup> In general it is from such amino-acids together with salts and carbohydrates that the cell builds up the colloids which form its characteristic structural apparatus. This appears highly complex in some forms of irritable tissue, as in voluntary muscle; in others, as in nerve, the essential structure appears relatively simple. What we call the "structural organization" of the cell is merely another name for the physical char-

<sup>4</sup>*Cf.* Child's interesting discussion of the relation between metabolism and structure in the *Journal of Morphology*, Vol. 22, 1911, p. 173.

<sup>5</sup>*Cf.* Folin's recent papers in the *Journal of Biological Chemistry*.

acteristics and arrangement of the solid colloidal material.

However simply organized a cell may seem, there are certain elements of structure which appear always to be present, and to play a fundamentally important rôle in stimulation and in other life-processes. These are the *membranes*. Most, if not all, living cells are delimited from the medium in which they live by thin semi-permeable colloidal surface-films, the so-called plasma-membranes. Similar semi-permeable partitions are often found in the cell-interior, *e. g.*, about nuclei, vacuoles, chromatophores, and other structures. They appear to be formed of the same colloids as the other protoplasmic structures, namely, proteins and lipoids. These colloids, like many other organic substances, have, when dissolved in water, a marked influence in lowering the surface-tension of the solvent. Any substance thus acting tends, by the operation of Gibbs's principle, to collect or condense on the free surfaces; if the substance is colloidal in nature it may there pass out of solution and form a solid surface-film or membrane; and it is probably under conditions essentially like these that the cell-membranes are formed. Artificial membranes similar in many of their properties to the plasma or nuclear membranes of cells may be formed in protein solutions about droplets of chloroform, mercury or other water-immiscible substances. Now the plasma-membranes of irritable cells undoubtedly play a fundamentally important part in stimulation, as will be seen below, so that it will be necessary to consider first some of the essential properties of these membranes before passing to the consideration of the stimulation-process itself and its modification by anesthetics.

The plasma-membranes are typically *semi-permeable* structures—so much so that living cells form in many cases the most

convenient and rapidly acting osmometers that we possess. If we place living cells, like plant-cells or blood corpuscles, in solutions of sugars, neutral salts and various other substances not in themselves immediately injurious to the cells, osmotic effects result from which the osmotic pressure of the solution relatively to that of the cell-contents can be estimated with great accuracy—as the researches of de Vries, Overton, Hedin and many others have shown. Two provisos are necessary in making use of living cells as osmometers: first, the dissolved substance must not by its own action impair the semi-permeability of the membrane, and second, it must not appreciably penetrate the membrane during the time occupied by the experiment. The plasma-membranes are in fact semi-permeable only in relation to certain classes of substances; towards others they show themselves freely permeable, and the character of these substances is important, because indication is thus afforded of the chemical nature of the materials composing the membranes. This is a matter of fundamental importance in the theory of anesthesia. Let us take for example a tissue composed of typical irritable cells, such as a frog's voluntary muscle. In studying the osmotic properties of this tissue, Overton found many years ago that the cells behaved in solutions of certain substances as if they were enclosed by strictly semi-permeable membranes; the chief of such substances are sugars, neutral salts, polyatomic alcohols like mannite, and amino-acids like glycocoll; but toward a large series of mainly organic substances, including alcohols, esters, aldehydes, hydrocarbon-derivatives and others, the membranes behaved as if freely permeable. Thus in an  $m/8$  (0.7 per cent.) solution of NaCl the muscle retains its weight unaltered, neither absorbing nor losing water; similarly in solutions

of sugar, mannite or glycecoll of the same osmotic pressure (of about 6 atmospheres). But if to an  $m/8$  NaCl solution we add (*e. g.*) alcohol in sufficient quantity to double the total osmotic pressure of the solution, it is found that there is no perceptible increase in its osmotic action on the muscle; in other words, the alcohol acts as if it entered the cell with the same readiness as the water. Many other substances show a similar power of freely entering the cell; others like urea, glycol and glycerine also enter, but more slowly. Similar observations in both animal and plant cells have shown that readiness of entrance into cells is a property that is closely correlated with solubility in fats or fat-like substances, including lipoids like lecithin. Substances not so soluble usually gain entrance slowly or imperceptibly. Overton drew from these facts the conclusion that the outer limiting layer or plasma-membrane of living cells consists in large part of lipoids, and that the characteristic osmotic properties of the cell depend on the presence of these substances in the membrane. Since substances that dissolve in lipoids will pass readily through lipid-impregnated partitions, this view explains why plasma-membranes are in fact readily permeable to such substances as a class. In its detailed application Overton's view has met with considerable opposition; thus, according to Overton, intra-vitam dyes like neutral red and methylene blue enter cells readily *because* of their solubility in lipoids; a certain number of exceptions to this rule have been pointed out by Ruhland and others; but in spite of these discrepancies there seems no doubt—when the whole of the evidence is considered—of the truth of Overton's main contention that lipid-solubility strongly furthers the ready entrance of substances into cells. Traube believes that the degree of surface-activity, rather than

of simple lipid-solubility, is the determining factor; this property shows a general parallelism with the lipid-water partition-coefficient, and hence also with the readiness of penetration. But there appear to be more exceptions to Traube's rule than to Overton's, while there are other and independent indications that the surface-films of cells are characteristically rich in lipoids; for instance, the fact that in the eggs of sea-urchins and other animals lipid-solvents are especially effective in causing the formation of fertilization membranes (a typical surface-effect) and in initiating cell-division; also the facts which I shall cite presently, showing that lipid-solvents are characteristically effective in altering the permeability of the plasma-membranes and in modifying their resistance to alteration by cytolytic substances.

I dwell upon these researches here because of the light which they throw on the question of the constitution of the plasma-membranes of cells, including those of the irritable tissues. They indicate that the membranes—and perhaps surface-structures in general—are especially rich in lipoids. Now lipid-soluble substances will tend, by the operation of the partition-law, to concentrate in the lipoids of the tissue; they will thus tend to gather in the membranes, and in so doing they will necessarily modify the physical state of these structures and so influence their physiological properties. We have already seen that the most striking effect which lipid-solvents produce on irritable tissues is to modify their irritability, and under certain conditions to suppress it altogether. This suggests that the membranes have a special relation to stimulation. We should expect on *a priori* grounds that the excitatory apparatus of the cell should be externally situated; and we are thus led to inquire if there is other and independent evidence

that the surface-films or plasma-membranes of the irritable elements play any such special part in stimulation.

There are in fact many indications that this is the case. Investigation of the conditions of electrical excitation—undertaken quite without reference to the problem we are considering—has shown that the semi-permeable membranes of irritable tissues are intimately concerned in stimulation. The first definite proof of this was brought forward in 1899 by Nernst. He was struck with the fact that Tesla currents (or alternating currents of high frequency) may be passed through irritable tissues (or through the human body) without causing stimulation; while if the frequency of the current is sufficiently lowered, but without altering its intensity, strong stimulation results. Now what does this mean? Evidently that the current must flow for a certain minimal time in a *constant direction* in order to stimulate. Mere conduction of a given quantity of electricity through an irritable tissue is not in itself sufficient to cause stimulation. There is some kind of cumulative effect depending on a steady flow in one direction. What physical peculiarities of the living tissue condition this remarkable peculiarity? Nernst pointed out that a living tissue in its relation to the electric current is an electrolytic conductor, which, however, is not homogeneous like an ordinary salt-solution, but peculiar in being sub-divided at intervals by semi-permeable partitions, the cell-membranes. When therefore the current starts to flow it carries as usual anions toward the anode and cations toward the cathode, but at the semi-permeable membranes this movement is blocked; the concentration of anions thus tends to rise above that of cations on the side of the membrane facing the cathode and *vice versa*, and the above behavior of the tissue may be partly explained if we

assume that these changes of concentration must reach a certain degree if stimulation is to result. For this effect time is required. Hence, if the current is reversed too soon, the stimulating effect is annulled, and the tissue remains unaffected. Now, if the assumption is true that stimulation is the expression of a change of electrical polarization, due to a change in the concentration of ions at the membranes, the time during which the current must flow in order to produce a given polarization-effect ought to correspond with that needed for a given stimulation-effect. Nernst's analysis shows that the polarizing action varies directly with the intensity of the current (*i. e.*, the quantity of electricity—*i. e.*, ions—transported in unit time) and with the square root of its duration ( $S = Ki\sqrt{t}$ ), and observations on a variety of irritable tissues have shown that the stimulating action of a given current does vary in essentially this manner with the duration of its flow in one direction (*i. e.*, inversely with the square root of the number of alternations in the case of an alternating current). It seems clear then that electrical stimulation is dependent on the polarization-changes produced by the current at the semi-permeable membranes of the irritable elements.

One main result of these investigations is thus to localize the stimulating action of the current at the semi-permeable membranes, and to indicate that a change in the electrical polarization of these membranes is an essential feature of stimulation. It is evident that this result does not constitute a complete analysis of the nature of stimulation. But it indicates that some change in the membrane is essential to this process. An electrical variation accompanies every normal stimulation and undoubtedly forms an inseparable feature of the process, but its conditions are still imperfectly under-

stood. There is evidence, however, that it is associated with a definite alteration in the osmotic properties of the membrane. The electrical properties of irritable tissues like muscle indicate that during life there exists permanently in the resting cell a difference of potential, equal roughly to 1/10 volt, between the outer and inner surfaces of the plasma-membrane. When the uninjured outer surface of a muscle or nerve is connected through a galvanometer with the exposed interior of the elements (cut surface) a current, the so-called "demarcation-current," flows from exterior to interior, indicating that the outer surface of the cells or nerve fibers has a higher potential than the interior. This potential-difference appears dependent on the semi-permeability of the plasma-membrane; it is absent in dead cells whose plasma-membranes have lost their semi-permeability, and it is diminished by the application of poisons which impair the normal semi-permeability. Briefly, the demarcation-current potential appears in some way to be inseparably connected with this semi-permeability of the membrane. Ostwald in 1890 suggested a possible explanation of this condition when he pointed out that a membrane might become the seat of a potential difference by interfering unequally with the diffusion of the anions and cations of an electrolyte contained within the cell. If the plasma-membrane allowed cations to pass outward freely, but prevented the passage of anions, a state of things would be produced comparable to what we observe in living cells. But the actual conditions are probably more complex than this, and experimental substantiation of Ostwald's suggestion has not been satisfactory. The subject is evidently one requiring further investigation. In any case, however, the existence of the demarcation-current potential appears dependent on the semi-perme-

ability of the membrane, and whenever the latter undergoes marked increase of permeability, this potential is invariably decreased. The electrical variation or action-current which normally accompanies stimulation may be theoretically accounted for by assuming that at this time the membrane undergoes a decided but temporary increase in permeability, *i. e.*, loses the semi-permeable properties which it possesses during rest, and there is independent evidence that this change actually occurs during stimulation. If this is the case the plasma membrane is the seat of the most constant and characteristic manifestation of stimulation—the electrical variation or action-current. The membrane responds to the stimulating condition by suddenly changing its permeability and hence its electrical polarization.

We are thus brought to the conclusion that the plasma-membrane is characteristically and intimately concerned in the stimulation process. During stimulation it appears to undergo a sudden and quickly reversible increase of permeability. The electrical variation is one expression of this change, but there are others as well. Thus the movements of sensitive plants, which occur under the same conditions of stimulation as those of irritable animal tissues, are due to a collapse of turgid cells, consequent upon a sudden loss of the semi-permeable properties of the plasma-membranes enclosing the osmotically active solution or cell-sap. Here at least is one irritable tissue where the connection between permeability-increase and stimulation seems unmistakable. It might be held that the existence of special osmotic motor mechanisms in certain plants affords no indication of the nature of the conditions in irritable animal cells; but even in animals there are in some cases very clear indications that stimulation is constantly associated with an increase

of permeability, as I shall shortly point out. Evidence from various sides thus proves the participation of the plasma-membranes in the stimulation-process. Just why a change in the permeability and electrical polarization of the plasma-membrane should influence so profoundly the metabolic and other activities of the cell is naturally a far-reaching question requiring further investigation, but there are many reasons for believing that the primary or initiatory phase of the stimulation-process is a change of this nature.

Let us return now to the question of why anesthetics interfere with the stimulation-process. In the first place they can be shown experimentally to interfere with both of the above characteristic manifestations of stimulation, (1) the action-current and (2) the change of permeability. If these are the critical or primary events, on which the other effects following stimulation depend, it is evident that suppression of these must involve a suppression of the entire series of processes resulting from stimulation, including the oxidations, the contraction-changes and the other special features of the response.

That the action-current as well as the mechanical response of a muscle is suppressed by anesthetization has long been known. In nerve also anesthesia abolishes the action-current. Now, on the foregoing hypothesis, the electrical variation is the expression of some alteration in the plasma-membrane, involving a temporary increase of permeability. Höber has found that potassium salts, which deprive nerves of irritability and render them locally negative, cause at the same time a visible alteration in the axis-cylinders; these structures swell and stain more diffusely; he found further that these effects are checked or prevented if the nerves are first anesthetized with ethyl urethane. Experiments on

voluntary muscle gave analogous results. If a frog's muscle is partly dipped into an isotonic solution of a potassium or rubidium salt the tissue contracts somewhat and becomes locally negative; this effect is also inhibited or retarded in the presence of an anesthetic.\* If the local negativity is the expression of a change produced by the salt in the colloids of the plasma-membrane, rendering the latter more permeable than before, Höber's results indicate that the anesthetic decreases the susceptibility to such changes of permeability. If this is the case we can partly understand why the anesthetized tissue becomes less susceptible to stimulation, since stimulation involves an increase of permeability.

Quite recently at Woods Hole I have investigated the question of the nature of anesthetic action in a somewhat different manner, using an organism which seems unusually well adapted to throw clear light on this subject. If an anesthetic acts by so modifying the plasma-membrane of the irritable cell as to render difficult or impossible the rapid variations of permeability which are essential to stimulation, it ought to act similarly on other cells, *i. e.*, it should protect these cells also against the action of permeability-increasing substances or agencies. If an organism can be found whose cells undergo immediate and obvious increase of permeability under conditions which at the same time cause stimulation, it should become possible to determine whether suppressing the stimulating action of a given agency is equivalent to a suppression of its permeability-increasing action. The two effects ought to show a definite parallelism if the above hypothesis is well-based. The organism which I have used is the larva of the marine annelid *Arenicola cristata*. This organism shows

\* Cf. Höber, *Pflüger's Archiv*, 1907, Vol. 120, p. 492.

anatomical features of the required kind. It is a small, worm-like trochophore about 0.3 mm. long, swimming by two ciliated rings and possessing a well-developed musculature of longitudinal fibers. The body cells are permeated with a yellow or brownish pigment, so that when the larvæ are collected in a dense mass (which can readily be done by taking advantage of their strong heliotropism) they appear dark brown in color. Now if such a mass of larvæ is brought suddenly into a pure isotonic NaCl solution, they instantly contract strongly and remain thus contracted for twenty or thirty seconds, after which they slowly relax. During the period of contraction the yellow pigment diffuses rapidly into the solution and colors the latter bright yellow; *i. e.*, strong stimulation of the muscle cells is associated with marked increase in the permeability of the pigment-containing cells. The cilia cease and undergo rapid disintegration at the same time. If now instead of using pure NaCl solution, we bring a similar mass of larvæ into NaCl solution to which a little calcium or magnesium chloride has been added, a strikingly different effect is seen. Stimulation is slight and transitory, there is no immediate loss of pigment, and ciliary action continues uninterrupted. The general toxic action of the NaCl is also greatly lessened. It can thus be shown that pure solutions of sodium salts cause strong stimulating and permeability-increasing effects, both of which are simultaneously prevented by the addition of a little calcium or other antitoxic salt. Prevention of permeability-increase runs parallel with prevention of stimulation. Magnesium salts in pure isotonic solution exhibit an action which is apparently the reverse of that shown by sodium salts. Larvæ brought into  $m/3$   $MgCl_2$  show no stimulation, no loss of pigment or destruction of cilia, and little or no

immediate injury. On the contrary all muscular movements cease in a few seconds and the larvæ remain permanently motionless during their stay in the solution (except for the cilia which remain active). The effect of the solution is reversible; on return after a few minutes to sea-water, the normal activities at once return. The magnesium salt shows typical anesthetic action, *i. e.*, it renders stimulation difficult or impossible. It also hinders increase of permeability. If larvæ that have lain in  $m/3$   $MgCl_2$  for a few minutes are suddenly brought into  $m/2$  NaCl, no immediate effect is seen—neither stimulation nor loss of pigment. The toxic action of the pure NaCl is also much less than when the transfer to this solution is made directly from sea-water. In other words, the  $MgCl_2$  renders the plasma-membranes resistant to the permeability-increasing or cytolytic action of the NaCl solution; and at the same time it renders the irritable elements resistant to stimulation. The action of the  $MgCl_2$  must depend on an alteration of the cell-surfaces, since this salt enters living cells with extreme slowness, if at all. We must conclude that in this instance at least the anesthetic action depends on a modification of the surface-layers or plasma-membranes of the irritable cells or elements.

I have found that lipid-solvent anesthetics produce effects which are essentially identical with those of  $MgCl_2$ . The case of ethyl ether, the most widely used of all anesthetics, may serve as an illustration. In a .7 per cent. solution of ether in sea-water *Arenicola* larvæ immediately cease all muscular movements; the cilia show more resistance to anesthesia and remain active. If now the larvæ are transferred to  $m/2$  NaCl solution containing the same proportion of ether—so as to preserve the state of anesthesia—no contraction or loss of pigment follows, the cilia continue their activ-

ity, and the injurious action of the pure NaCl is relatively slight. Bringing larvæ from normal sea water directly into ether-containing NaCl solution also causes little or no stimulation or loss of pigment, and the cilia and body cells are protected against the injurious action of the solution. Thus in the presence of the anesthetic the salt solution fails to show its normal stimulating and permeability-increasing action, and its toxic or cytolytic action is greatly diminished. Anti-stimulating and anti-cytolytic actions run parallel with each other.

I have studied the action of a large number of anesthetics in this manner. Those which promptly and completely anesthetize *Arenicola* larvæ in sea-water show, when dissolved in NaCl solution in the proper proportions, effects which are essentially identical with those just described, though varying in degree with the different anesthetics. Alcohols (methyl, ethyl, propyl, butyl, amyl, capryl), the urethanes (methyl, ethyl, phenyl), other esters like ethyl nitrate, acetate, propionate, and compounds like chloretone, acetanilide, paraldehyde, nitromethane, chloroform, acetonitrile, all decrease or prevent the stimulating and permeability-increasing action of pure NaCl solutions when present in the concentrations which cause typical anesthesia in sea-water. They also show well-marked protective or anti-cytolytic action. Other anesthetics, among which are chloral hydrate, benzol, phenyl urea, and chloralose, act more slowly than those just mentioned, and if larvæ are brought suddenly into their solutions in  $m/2$  NaCl, stimulation and loss of pigment occur very much as in the pure salt solution. A parallelism between permeability-increasing action and stimulating action is thus seen throughout. If the one effect is decreased or prevented so also is the other.

The exact concentrations most favorable for anesthesia and prevention of permeability-increase are characteristic for each substance and have to be determined empirically. In a series of homologous compounds, like the alcohols or the fatty acid esters, the molecular anesthetic action increases rapidly with increase in molecular weight and in lipid-water partition-coefficient. The same is true for the vertebrate central nervous system, as Overton and Meyer have shown. Overton's observations on tadpoles show a close parallelism with my own in these respects. The concentrations required to anesthetize *Arenicola* larvæ are, however, higher in every case—usually three to five times higher—than for tadpoles. Possibly the higher salt content of the tissue-media in marine animals is responsible for these differences; the order of relative action is the same in both organisms.

To sum up—it would thus seem that anesthetics produce their essential effects by modifying the properties of the semi-permeable plasma-membranes of the irritable tissues, making these structures more resistant to changes of permeability than normally. Since variations of permeability are essential to stimulation, the irritable tissue is thus rendered temporarily insensitive or irresponsive.

How does the anesthetic produce these effects? Osterhout has recently shown that anesthetics decrease the electrical conductivity of plant tissues, apparently by decreasing the permeability of the plasma-membranes to ions;<sup>7</sup> and it may be that in irritable animal tissues also the permeability normal to the membranes is similarly decreased during anesthesia. If the distinctive action of the anesthetics is to decrease permeability, its presence in the tissue will naturally oppose increase of per-

<sup>7</sup> SCIENCE, Vol. 37, 1913, p. 111.

meability and hence interfere with stimulation. The osmotic motor mechanisms of plants, whose action depends on sudden increase of permeability, may in fact readily be rendered irresponsive by anesthetics, as Claude Bernard pointed out long ago in his classical lectures on the life-phenomena common to animals and plants. Or the explanation may be somewhat different. The anesthetic may leave the resting permeability of the membrane the same as before—or perhaps may change it in either direction—but alter its properties so as to decrease the readiness with which the permeability is changed by other agencies acting on the membrane. Changes of condition, electrical or otherwise, that normally act as stimuli would then no longer affect the membrane, and would hence cease to stimulate. But whatever general interpretation we adopt, it is demonstrable that the properties of the membranes are altered during anesthesia in such a way as to make increase of permeability more difficult than in the normal sensitive state of the irritable tissue.

Is this the whole explanation of the anti-stimulating action of anesthetics? Nothing but further experimentation can answer such a question. Suppression of stimulation is however the essential effect to be explained. It must be remembered that any specific response to stimulation comprises a series of mutually interdependent processes, beginning with the one caused directly by the external agent, and ending with the special physiological activity, or response, characteristic of the tissue. It seems more likely that the anesthetic interferes with the *initial* process of such a series than with one occurring later—such as the increase in oxidation or other special effect. The evidence which I have cited indicates in fact that the primary process in stimulation is a *membrane-process*, and

that it is this process which is modified by the anesthetic. This is why the succeeding and outwardly more evident effects of stimulation are also modified in the way that we observe.

It is well known that an influential group of physiologists, headed by Verworn, maintain that a suppression or prevention of oxidation-processes is the essential basis of anesthesia. Various facts are adduced in support of this theory. During anesthesia the oxidative metabolism of the tissue is diminished. This fact in itself is equivocal; stimulation causes increased oxidations in many tissues, and suppression of stimulation prevents this effect along with the others. Lack of oxygen arrests many physiological activities that are dependent on its presence, but this fact again does not justify Verworn's identification of narcosis and asphyxia. Other facts seem more consistent with this view. Fröhlich and Heaton find that the recovery of nerves from anesthesia is imperfect or delayed in absence of oxygen; Ishikawa, another pupil of Verworn's, finds the same for *Amœbæ*; from which they conclude that suppression of oxidations is the essential feature of the condition. These observations merely show once more that the cell or tissue requires oxygen in order to exhibit its normal properties. Mansfeld finds that the concentration of anesthetic required to anesthetize tadpoles is less when oxygen is deficient than when it is abundant; *i. e.*, anesthesia and asphyxia show additive relations to each other. This again is equivocal. The action of nerve-cells is intimately dependent on a good supply of oxygen; when oxygen is deficient their excitability is lowered, and along with this the degree of anesthesia required to abolish excitability. Other parallels of similar nature seem open to objections of the same kind. On the other hand, nerve trunks resist the lack of oxy-

gen or the presence of cyanide (which renders unavailable the oxygen present) remarkably well. Warburg finds that fertilized sea-urchin eggs anesthetized by phenyl urethane, so as to be incapable of cell-division, show nevertheless the same oxygen-consumption as the normal unanesthetized eggs. Again, lack of oxygen interferes only gradually with the ciliary action in many organisms, while anesthetics in sufficient concentration arrest the movement instantly. It seems necessary to conclude from these facts that the essential action of the anesthetic is of a more general kind, and consists in incapacitating some mechanism which is essential to the normal activities of the cell, whether these immediately require oxygen or not.

The evidence which I have reviewed indicates either that this mechanism is the plasma-membrane itself, or that it is closely dependent on the condition of the plasma-membrane. Any condition that renders the membrane incapable of responding to changes of condition by rapid changes of permeability and of electrical polarization has an anesthetic influence. This modification in the properties of the membrane may be produced either by changing the general condition of the colloids forming it—as in the case of magnesium salts or electrolytes in general—or by specifically altering the state of the lipid-components, as by organic anesthetics. It is impossible to say at present precisely why the solution of an anesthetic in the lipoids of the membrane should thus alter the properties of this structure. The nearest physico-chemical analogy seems to be the so-called “protective action” of colloids, as exemplified in those cases in which the presence of one colloid interferes with or prevents changes of aggregation-state in another, *e. g.*, when gelatine prevents the precipitation of colloidal gold or platinum

by a neutral salt like sodium chloride. Apparently the lipoids are related to the other colloids of the membrane in such a manner that the condition of the lipoids affects the entire properties of the colloidal structure, and so determines the effect which an electrolyte like NaCl, or a stimulating condition like an electric shock or mechanical impact, may have upon it. Hence when a lipid-solvent acts upon the membrane, and dissolves in the lipoids of the latter, it may profoundly change the physical properties of the membrane and hence the responsiveness of the whole tissue or organism to stimulation. On this view the membrane is a main controlling factor in cell-processes, and by changing its state we may alter the entire physiological activity of the cell.

UNIVERSITY OF PENNSYLVANIA

#### PSYCHOLOGISTS AS ADMINISTRATORS<sup>1</sup>

CASUAL statements have frequently been made to the effect that many psychologists leave their professional careers to become administrators of one sort or another, or carry on executive work of a definite kind in addition to their activities as psychologists, with the appended implication that psychology, as a science, suffers a proportionately greater loss of effective workers on this account than do the other sciences. As illustrations of this loss, not a few well-known examples are cited. At first blush, the generalization thus made might be classed under the fallacy of *post hoc, ergo propter hoc*, but in order to escape this charge ourselves, we must submit the matter to some statistical presentation.

The executive positions to which academic men are obviously called are presidencies of colleges and universities, and deanships of departments within colleges and universities. Farther down the scale, viz., directorships of laboratories and headships of divisions and

<sup>1</sup>Read before the meeting of the Experimental Psychologists at Wesleyan University on April 12, 1913.

specific departments, the positions are often only nominal in nature and vary so much from place to place in their attached duties that it does not seem wise to include them in our discussion. The question arises, then, as to which disciplines out of a given group contribute the most men for these executive positions and in what proportions they contribute them. To answer this we selected, from a list of colleges and universities in the United States for the year 1910-11,<sup>2</sup> those institutions which are neither denominational nor technically specialized. This list of 177 institutions was subdivided into those whose enrollment of students was above the 1,000 mark and those whose enrollment was below that mark, with the hope that this crude distinction between the large institution and the small might bring to light a difference in the kind of administrator demanded. The names of the presidents were then looked up in "Who's Who in America" in order to determine their fields of professional interest before they assumed charge of their administrative work. Where interest was considered to be equally divided in several fields, the count was fractionated accordingly. The results are thrown into two classifications; the first may be considered as absolutely determined, the other as relatively determined. Concretely, in the first case, the disciplines are presented in order of rank based upon the per cent. of representation in all the disciplines found; in the second case, a half-dozen sciences are chosen, and the relative rank of representation is given in terms of a per cent. based upon the total representation in these few sciences. The selection of these sciences was made on the basis of a possible comparison of relative worth. Unfortunately there were no available statistics for all disciplines dealt with in the first classification, but in the "Biographical Directory of American Men of Science,"<sup>3</sup> the author found a scale of pro-

portionate values which served as a means of possible interpretation in the second classification. In this directory of over 4,000 names, the relative number of men engaged in about a dozen sciences is given. Some of these sciences are not represented in our lists and are, therefore, not relevant to this discussion. We are forced to limit ourselves, consequently, to the following six sciences to which are attached the corresponding relative per cent. of men engaged in the given activity on the basis of the total number engaged in all of the six activities: biology (27 per cent.), chemistry (22 per cent.), physics (21 per cent.), geology (14 per cent.), mathematics (10 per cent.), and psychology (6 per cent.). The same method of classification was used with a list of 97 deans of colleges and of college departments of universities which were not specialized in profession, *i. e.*, schools of "applied science," "engineering," "medicine," "theology," etc., were not considered because they usually always demanded an executive whose interest lay in the corresponding field of activity. These names were chosen from the 1910-11 catalogues of 42 leading colleges and universities.

## CLASSIFICATION 1

111 Presidents of Institutions below 1,000 Stu- dent Enroll- ment	Per Cent.	66 Presidents of Institutions above 1,000 Stu- dent Enroll- ment	Per Cent.	97 Deans	Per Cent.
Theology .. 23		Education .. 20		Mathematics 16	
Mathematics 13		Chemistry .. 15		Class. Lit ... 12	
English .... 10		Philosophy . 10		English .... 12	
Education .. 8		Mathematics 9		History .... 10	
Mod. Lang's 7		Polit. Science 9		Polit. Science 10	

## CLASSIFICATION 2

28 Presidents of Institutions below 1,000 Stu- dent Enroll- ment	Per Cent.	21 Presidents of Institutions above 1,000 Stu- dent Enroll- ment	Per Cent.	38 Deans	Per Cent.
Biology .... 5			7		11
Chemistry .. 33			11		13
Physics .... 24			14		23
Geology .... 5			4		2
Mathematics 28			52		40
Psychology . 5			12		11

<sup>2</sup> This list was furnished by the *World's Almanac* for that year and corroborated by reference to the Report of the Commissioner of Education for the same year.

<sup>3</sup> New York, 1911.

The totals for the second classification are: biology 7.7 per cent., chemistry 19 per cent., physics 20.3 per cent., geology 3.7 per cent., mathematics 40 per cent., and psychology 9.3 per cent.

These tables show, then, that (1) under the absolute classification in the first array, psychology does not appear at all in the rank of the first five disciplines represented, but that (2) under the relative classification of our second array, whereas psychology has the fewest number of representatives engaged in activity in its field, it stands, on the average, fourth on the list of executive representatives, and, if we get its comparative rank in terms of the relative number engaged in the profession, we find that it stands next to the top. This result was obtained by dividing the average per cent., as given in the second table, by the per cent. of number engaged in the profession as outlined above. This value might be termed, for the sake of this discussion, the efficiency-value and results as follows: mathematics 4.00, psychology 1.55, physics .94, chemistry .86, biology .29, and geology .24.

Another investigation was carried on from a slightly different angle. This study was not, like the second classification, a comparative one in terms of other sciences. The question arose as to how many psychologists of repute have been engaged in executive work since they began activity in the field of the science. For this purpose the membership list of the American Psychological Association and Cattell's "American Men of Science" (2d, 1911, edition) were consulted. From the former, a list of about 300 names, 150 names of persons who were recognized in the latter as psychologists were drawn. These names were subdivided into two groups: those recognized as eminent, *i. e.*, among the 1,000 scientists of the country, and, the remainder, those who were not so considered. It was deemed that they had performed executive work if, after they had held some responsible position in psychology, they had become administrators in the sense of the above classifications, or if they had held, or were holding, such positions as superintendencies or prin-

cipalships of schools, directorships of institutions, or other equivalent positions. It was found that in the first group there were 12 executives out of a possible total of 42 (29 per cent.), and in the second group 36 out of 108 (33 per cent.) came under the rubric of executives. This, the investigator believes, is a fairly large portion of the total, but there is, of course, no ground for believing that psychology is making a better showing in this respect than other sciences, except in so far as the second classification, given above, distinctly indicates it. Undoubtedly, on the score of this classification, the conclusion that psychology, next to mathematics, is contributing more executives relatively than the other sciences mentioned, is valid; and the supposition that the comparison between these sciences, chosen only with reference to available statistics, is fair, must be left to the judgment of the readers of this article.

CHRISTIAN A. RUCKMICH

CORNELL UNIVERSITY

#### THE PLANT INDUSTRY HALL OF THE UNIVERSITY OF NEBRASKA

On June 10 the University of Nebraska dedicated a new building known as the Plant Industry Hall, to be occupied by the departments of agricultural botany, in charge of Professor Wilcox; horticulture, in charge of Professor Emerson, and entomology, in charge of Professor Bruner. The new building is 140 by 65 feet, and consists of three stories above the basement. It is of strictly fire-proof construction throughout.

Short addresses were made by Architect Chowins, Regent Whitmore and Dean Burnett. The principal address on "Practical Science" was given by Professor Dr. John M. Coulter, of the University of Chicago, and will be printed in *SCIENCE*. These addresses were followed by the ceremony of conferring the honorary degree of doctor of agriculture upon Dean Herbert J. Webber, of the University of California, and Dean Albert F. Woods, of the University of Minnesota.

In conferring these degrees, Chancellor Avery said:

Herbert John Webber, bachelor of science; master of arts; doctor of philosophy; charter member Botanical Seminar, and early assistant in the department; distinguished physiologist, pathologist, and plant breeder; discoverer of motile sperms in *Zamia*; investigator of double fertilization in maize; improver of plants useful for food and clothing; member of learned societies.

Albert Fred Woods, bachelor of science; master of arts; charter member Botanical Seminar, and early assistant in the department; notable investigator; as an administrator distinguished for services in the United States Department of Agriculture; dean of a great college of agriculture; director of a famous experiment station; author and man of affairs.

#### THE PHYSICAL LABORATORY OF WASHINGTON AND JEFFERSON COLLEGE

THROUGH the generosity of an alumnus, \$50,000 was given to Washington and Jefferson College in June, 1911, for the erection of a physics laboratory. An attempt was made to keep within the appropriation, but the cost of erection ran up to \$51,090. It is built of cream-colored brick, and measures 60 by 90 feet. The floors are of reinforced concrete, while the walls are solid brick 22 and 18 inches thick. All the laboratories are provided with piers running down to the rock underneath the building or with slate ledges built into the wall. The first floor contains elementary laboratories, workshop, storage room, constant temperature room, and one private laboratory. On the second floor are laboratories for work in electricity and light. Besides there is a chemical laboratory, a supply and stock room, and two private laboratories for advanced work. The third floor is given over to the lecture room, with accompanying preparation and apparatus rooms, a general laboratory for work in mechanics, a dark room, and a laboratory for advanced optics. Electric power is distributed from the dynamo room on the first floor, while the battery distributing center is on the third floor. A reference library and reading room is located on the second floor. The laboratories are all supplied with gas, hot and cold waters, compressed air and exhaust; also, direct, alternating and battery currents are available in

each laboratory for power and experimental purposes.

The laboratory was dedicated on January 16, 1913, celebrating the 111th anniversary of the chartering of Jefferson College at Canonsburg. The address was made by Professor A. G. Webster on "Physical Laboratories and their Relation to the Advance of Civilization."

#### SCIENTIFIC NOTES AND NEWS

HARVARD UNIVERSITY has conferred its doctorate of science on Dr. Chas. D. Walcott, secretary of the Smithsonian Institution.

AMONG honorary degrees conferred by Yale University were doctorates of science on Dr. A. A. Noyes, professor of theoretical chemistry of the Massachusetts Institute of Technology, and on Dr. S. W. Williston, professor of paleontology at the University of Chicago; the doctorate of laws on Dr. John G. Hibben, president of Princeton University, and Dr. David F. Houston, secretary of agriculture, and the master of arts on Dr. Harvey Cushing, professor in the Harvard Medical School.

The University of Pennsylvania has conferred its doctorate of laws on Dr. G. W. Goethals, chief engineer of the Panama Canal.

BROWN UNIVERSITY has conferred the degree of doctor of science on Mr. Frank M. Chapman, curator of ornithology in the American Museum of Natural History.

WESLEYAN UNIVERSITY has conferred the doctorate of laws on Dr. Charles H. Judd, director of the school of education of the University of Chicago.

TUFTS COLLEGE has conferred the doctorate of science on Admiral Robert E. Peary and the degree of doctor of science on Dr. Alfred C. Lane, Pearson professor of geology and mineralogy in Tufts College.

DURING commencement week at Colorado College there was celebrated the twenty-fifth anniversary of President W. F. Slocum's administration. The following honorary degrees were conferred on scientific men: the degree of doctor of science on Professor T. D. A. Cockerell, of the University of Colorado,

and on Professor William Strieby, of Colorado College, and the degree of doctor of laws on H. A. Howe, of the University of Denver.

DR. JOHN M. MECKLIN has resigned the professorship of mental and moral philosophy at Lafayette College because his teaching was regarded as not in accord with the standards of the Presbyterian church.

THE first Loubat prize of \$1,000, for the best work printed and published in the English language upon the history, geography, archeology, ethnology, philology or numismatics of North America, during the quinquennial period ending July 1, 1913, has been awarded by Columbia University to George Louis Beer, of New York (A.B., 1892), for his series of works on the British Colonial System. The second prize of \$400 has been awarded to Dr. John Reed Swanton, of the Bureau of Ethnology, Washington, D. C., for his two works, one on "The Indian Tribes of the Lower Mississippi Valley," and the other, "Tlingit Myths and Texts."

THE Académie Française has awarded the Grand Prix Broquette Gonin, of the value of \$2,000, to Professor Grasset, of Montpellier. The prize is for "the author of a work, philosophic, political, or literary, which shall be judged to be of a nature to inspire the love of the true, the beautiful, and the good." Professor Grasset, who is known for his researches on the nervous system, is also the author of several works on questions of psychology, moral responsibility and the philosophy of practical life.

PROFESSOR ROBERT ANDREWS MILLIKAN, of the department of physics in the University of Chicago, was elected on May 23 president of the local chapter of Sigma Xi. Dr. Henry C. Cowles, of the department of botany, was elected vice-president of the chapter, and Dr. Rollin T. Chamberlin, of the department of geology, secretary.

DR. HENRY A. BUMSTEAD, professor of physics in Yale University, has been given leave of absence for the coming academic year.

PROFESSOR EDWARD ALEXANDER WESTERMARCK, professor of sociology in the Univer-

sity of London, has accepted an invitation to give four lectures next year at Brown University.

DR. C. S. SHERRINGTON, F.R.S., professor of physiology at Liverpool, has been appointed an additional member of the British departmental committee on the lighting of factories and workshops.

MR. A. J. MUTCHLER has been appointed assistant in the department of invertebrate zoology of the American Museum of Natural History.

MR. A. C. FRASER, of Cornell University, has come to the New York Botanical Garden to assist during the coming summer in the experimental work in plant breeding.

DR. JOHN DETLEFSEN, assistant professor of genetics in the University of Illinois, will spend the summer visiting the principal European genetic laboratories.

NELSON C. BROWN, M.F., Yale Forest School, in charge of forest utilization in the New York State College of Forestry, is spending the summer studying forest conditions in Germany and Austria.

THE Amazon expedition of the University of Pennsylvania, in charge of Dr. W. C. Farabee, arrived in Para, Brazil, last week. Here Dr. Farabee will charter a vessel for the trip in the Amazon regions, according to the original program. The Brazilian government is interested in the expedition, and is aiding the university in various ways.

DR. FRANK HARTLEY, professor of clinical surgery in Columbia University, has died at the age of fifty-nine years.

THE U. S. Civil Service Commission announces an examination for assistant in plant histology, on July 16, to fill a vacancy in this position in the Bureau of Plant Industry, Department of Agriculture, at a salary ranging from \$1,200 to \$1,620 a year.

THE material collected by the third African expedition, under Dr. W. S. Rainsford, has been received at the American Museum of Natural History. It contains specimens of

black rhinoceros, East African buffalo, eland, leopard, cheetah, antelope and monkey.

THE Tokyo Statistical Society of Japan, having recently suffered the loss by fire of a valuable library it had been thirty-three years in gathering, John Hyde, former statistician of the Department of Agriculture, has presented the society with 3,000 volumes of statistical literature to form the nucleus of a new collection. In addition to official publications of 52 countries, printed in twelve different languages, the gift includes the transactions for a long series of years of most of the leading statistical societies of the world, as well as a large number of miscellaneous books of reference. In accepting the gift, the president of the society, Baron Sakatani, former finance minister, announced that the library would be given the name of the donor.

AN ecological conference will be held at the University of Chicago during the summer quarter; the following series of illustrated lectures on "The Relation of Plants and Animals to Environment," will be given beginning July 16, when Professor Henry C. Cowles, of the department of botany, will speak on "Principles and Problems of Ecology as illustrated by Plants." On July 18 Dr. Victor E. Shelford, of the department of zoology, will discuss "Principles and Problems of Ecology as illustrated by Animals." Lecturers in the conference from other institutions will include Arthur C. Tansley, of Cambridge University, who speaks on "British Landscapes"; Professor Carl Schröter, of the University of Zurich, on "The Lake Dwellings and Lake Dwellers of Ancient Switzerland"; Professor Stephen A. Forbes, of the University of Illinois, whose subject is "Fish and their Ecological Relations," and Professor William M. Wheeler, of Harvard University, who will discuss in two lectures "The Habits of Ants."

It is difficult to realize the enormous quantities of brick used annually in Greater New York. During 1912 the consumption was over 1,000,000 thousand. The principal source of this vast quantity is the Hudson River region, which extends along both sides of the

river from New York City to Cohoes and embraces ten counties, nine in New York and one in New Jersey. Other sources of supply are the Raritan River region of New Jersey and the Connecticut region. The year 1912 was one of unusual interest in the Hudson River region. It opened with an increasing demand for brick, and the price for common brick was \$7 a thousand, compared with \$4.25 in 1911. For several years the use of cement or concrete in construction appeared to be displacing brick to some extent, but owing to the strong "back to brick" movement the year 1912 saw in the New York market a change favoring brick as the best building material for many purposes. Influences that have contributed to this change are the failure of some concrete buildings, the advertising campaign carried on by the brickmakers, and the improved quality of the Hudson River brick. The average price was the highest since 1906. The marketed product in 1912 was larger than that of 1911 and would probably have been still greater but for the scarcity of labor, especially at Haverstraw, and the strike among the brickmakers in the Newburgh district. The strike, however, was of short duration, but the scarcity of labor drawn away by large construction enterprises, such as the Catskill aqueduct, railroad extensions and subway operations, was a serious drawback to the Hudson River brickmakers in 1912. This condition was so serious that the operators resorted to night work and rainy-day work in loading barges and imported laborers from the South. An important development during the year was a large increase in the use of Raritan River brick in New York City, which has for some years been drawing on the Raritan River region. In 1912 the demand for this brick was very much greater than ever before. On the whole the year may be considered one of prosperity. The demand was good, prices were high, the mild weather toward the end of the year permitted shipments to its very close, and while the marketed product was not the largest recorded, it was considerably larger than that of 1911. The statistics gathered by Jefferson Middleton, of the United States Geological

Survey, show that the number of brick marketed in the Hudson River region in 1912 was 1,019,259,000, valued at \$5,850,770, or \$5.74 a thousand, compared with 926,072,000 brick in 1911, valued at \$4,717,633, or \$5.09 a thousand. This was an increase in 1912 of 93,187,000 brick and of \$1,133,137 in value. The number of operating firms reporting in 1912 was 126. As in other branches of the clay-working industry, the number of active firms reporting is not equivalent to the number of yards, for many firms have more than one yard.

#### UNIVERSITY AND EDUCATIONAL NEWS

WELLESLEY COLLEGE has received an anonymous gift of \$100,000.

In addition to \$250,000 appropriated for a building for the New York State College of Forestry at Syracuse University, the legislature appropriated \$50,000 for the maintenance and development of the work for the coming year. Last year through the kindness of Mrs. Russell Sage, who gave something over \$80,000, a Division of Agriculture was organized at Syracuse University. This division is giving agricultural instruction for teachers and general work for students of other colleges. These courses in agriculture are given without state or national aid.

GOVERNOR SULZER has signed a bill making the New York American Veterinary College, allied with New York University, the state veterinary college for the eastern part of the state. No appropriation of money was made in the bill.

SOPHIE NEWCOMB COLLEGE, the woman's department of Tulane University, will shortly erect on its new site on Audubon boulevard, adjoining the university proper, four new buildings to cost \$600,000.

It is announced that the executors of the late Sir J. Wernher, Bart., have completed the allocation of the £100,000 bequeathed to them to be devoted to charitable and educational purposes. £35,000 has been allotted to charitable and educational purposes in South Africa, and £65,000 to some 150 different institutions in Great Britain. The grants for

scientific and educational purposes include: to the Institute of Mining and Metallurgy, £5,000; the Imperial Service College, Windsor, £2,500; the London School of Tropical Medicine, £1,500.

THE school of medicine of the University of Pittsburgh arranged a medical program in connection with the commencement week exercises. Special clinics were arranged at the hospitals affiliated with the university, as well as laboratory demonstrations at the medical school building on the university campus.

THE Rush Medical College, Chicago, which has for a number of years strongly recommended a fifth clinical year as interne in a hospital, or its equivalent, has made this compulsory for the class entering in 1914. This fifth year is to be spent either in graduate work in one of the departments of the college or as an interne in an approved hospital under the constant supervision of the college faculty.

A GREAT increase in the enrollment has marked the progress of the college of agriculture of the University of Illinois during the past few years. In 1895-96 there was a total enrollment of 14 students; in 1900-01, 159 students; in 1909-10, 660 students and in the present year, 1912-13, there was a total number of 905. The college of agriculture is graduating an ever-increasing number of men. The larger percentage of these graduates are now engaged in practical agriculture. This is shown by statistics being gathered at the present time. Out of ninety-three men graduating this year, forty-four expect to go into actual farming operations; ten expect to enter experimental work at the University of Illinois; ten to teach; eleven will do graduate work; five are going to work for large implement companies, and the rest will be employed in work more or less connected with agriculture.

DR. L. H. BAILEY has resigned the directorship of the New York State College of Agriculture, Cornell University.

DR. PAUL G. WOOLLEY, dean of the medical department of the University of Cincinnati, has resigned this office but retains his professorship.

THE presidency of Tulane, vacant by the resignation of President Craighead a year ago, has been filled by the election of Professor Robert Sharp, dean of the graduate school, acting president during the past year, and for thirty-two years a member of the faculty.

MR. GEORGE WHEELER HINMAN, until recently editor and proprietor of the Chicago *Inter-Ocean*, has been elected president of Marietta College to succeed the late Alfred T. Perry.

MISS JOSEPHINE T. BERRY, of the Washington State College, has been elected professor of nutrition and home economics at the University of Minnesota.

HARRY G. HAKE, of the University of Illinois, has been appointed assistant professor of electrical engineering at Washington University. Joseph C. Stephenson has been appointed instructor in zoology.

AT Vassar College Winifred J. Robinson, Ph.D. (Columbia, 1910), has been advanced from instructor to assistant professor of botany.

MR. W. A. MACDONALD, B.S.F. (Michigan Agricultural College, 1913), has been appointed instructor in forestry in the New York State College of Forestry at Syracuse University.

#### DISCUSSION AND CORRESPONDENCE

##### THE LAWS OF NOMENCLATURE IN PALEONTOLOGY

TO THE EDITOR OF SCIENCE: In the course of an interesting and able communication by Dr. Matthew upon "The Laws of Nomenclature in Paleontology" in SCIENCE of May 23, 1913, pp. 788-792, the following paragraph occurs on page 792. The italics here are those of the present writer.

*Deinodon* Leidy is determinable as to family, but is not determinable generically, as the genera of carnivorous dinosaurs are now distinguished. The same is true of a whole series of genera and species described by Leidy and Cope from the Judith River. The treatment of types and referred specimens of these genera by paleontologists as specifically distinguishable or identical has sadly misled Dr. Peale in his recent discussion of the vertebrate evidence as to the age of the Judith River beds, leading him to present as conclusive

evidence of identity in age a correspondence in fauna which to those who know the nature of the specimens on which the lists are based is no evidence at all.

Inasmuch as the writer hereof is mentioned in this paragraph and this mention may lead to some misapprehension, the following notes are presented. Now as to *Deinodon*, it is submitted that what has been done or is to be done with this genus in the future does not seem to enter the case. Suffice it to say that not only is it mentioned generically by Hatcher and others, but Hatcher in Bulletin 257 of the U. S. Geological Survey (p. 85) gives also a number of species of the genus, and I believe that I am not assuming too much when I take it for granted that others who have referred to these species, or any of them, were referring to the same thing. That the paleontologists may have been at sea in regard to the exact determinations, and that the material is fragmentary and imperfect was as well known to me at the time of writing as to the paleontologist himself, but as the names are a matter of record I think I was justified in using them, no matter what becomes of them in the future, especially as Hatcher, Osborn and others have made important deductions from their occurrence. These remarks apply to the whole series of genera and species referred to by Dr. Matthew. It is rather interesting to have a vertebrate paleontologist make the statement that "correspondence in fauna is not conclusive evidence of identity in age," especially as it rather confirms the statement made by me in my article on the Judith River formation (*Journal of Geology*) wherein, in discussing the evidence of vertebrate fossils on the question of the age of the Judith formation, I say:

Either the beds are identical in age or vertebrate paleontology has no place in stratigraphic geology and *non geologia sine paleontologia* becomes *non paleontologia sine geologia*.

The writer does not pretend to be a vertebrate paleontologist, nor is he able or willing to pass upon the value of the material studied by them, but he submits that he must be confined to what has been published by them, as

must all who use their material. It is impossible to go back of their record. As they (the vertebrate paleontologists), although fully aware of the fragmentary condition of the material they dealt with, gave not only generic but specific names and made certain deductions from their use, I do not quite understand why I was so sadly misled in using the names as I did, unless, as I said in my paper, vertebrate paleontology is of no use to the stratigraphic geologist. I wish to state here that I thoroughly believe in the value of the evidence of vertebrate paleontology.

While upon this subject, I wish to refer to another point, not, however, mentioned by Dr. Matthew. By some I have been criticized for not including in the lists of vertebrate fossils in my paper all that have been in any way referred to the Judith River formation, from all localities in Montana and in Canada, but it was my idea to limit the list to those found in the typical region of the Judith River formation, and on page 753 of my article on the "Stratigraphic Position and Age of the Judith River Formation" it is distinctly stated that Hatcher's list of Judith River vertebrates is used after the elimination of "all the species which are duplicated under other names" and also of all which come from beds not certainly of Judith age or that occur outside the typical area (the Judith Basin of Montana).

A. C. PEALE

#### ICE CAVES

THE contribution to *The Popular Science Monthly* for March on "The Sweden Valley Ice Mine," by Marlin O. Andrews, calls for some comment and criticism. In the first place it is calculated to convey the impression that such phenomena as he describes are exceedingly rare, whereas they are fairly common in middle latitudes—especially in limestone districts. In the second place the explanation given of such phenomena is faulty.

The writer of the above mentioned article appears to have come to his subject rather poorly equipped as regards geological knowledge, and though by his own statements supplied by the Federal Survey with information

concerning the literature of the subject, to have availed himself very little of it. To begin with, his introduction detailing tradition as to presence in the region of silver mines known only to the Indians, in regard to the reliability of which he appears to have little doubt, does not serve to enhance our confidence in his ability to describe or explain geological phenomena.

Such traditions of "lost silver mines" prevail in nearly every community, but we hardly expect to find a man of science giving credence to them; especially if it is in a region where such mines are a geological impossibility. Potter County, Pa., is in such a region. It may be true that the county has never been covered by a detailed geological survey (a portion of it however has been covered by the Federal Survey and an account given of it in the Gaines Folio), but enough is known geologically of that portion of Pennsylvania to enable us to postulate the presence there of unaltered and little deformed sandstones and shales of Devonian and Carboniferous age, and to assert the entire absence from them of deposits in appreciable amounts of either lead or silver ores. Will the time never come when the diffusion of elemental geological knowledge is such as to render impossible the floating of such absurd "lost-silver-mine-known-only-to-the-Indian traditions"? Where did these Indians acquire their expert mineralogical and metallurgical knowledge that would enable them to detect silver in an ore or extract it therefrom? We know that when discovered by white men the American Indian was living in the "Stone Age" and utterly unacquainted with the extraction of metals from their ores.

When it comes to the account of the ice mine itself, the description in the article must be considered very inadequate from a geological point of view. Was the shaft sunk on undisturbed strata or on talus accumulation? If on the latter, we appear to have here a case of "talus ice accumulation," of which there are many instances. There is at least one other of these in Pennsylvania, if I remember cor-

rectly, either in Center or one of the adjoining counties.

The finding of "petrified wood" and "bones" possibly "human," in sinking the shaft, would seem to indicate talus deposits, but the "fern impressions" point to little shifted carboniferous strata.

Is the wood really "petrified," that is silicified, or does it consist of sandstone casts of same? If the latter, and in strata in place, it indicates carboniferous, and there could be no human bones associated with it. The reference to "loose shale, sharply inclined" up (?) the hill, might indicate overplacement due to creep. The nature of the strata (sandstone and shale) composing the Devonian and Carboniferous of that region would preclude the possibility of extensive underground channels or caverns, which require limestone and would consequently render very problematic the explanation proposed by Mr. Andrews for this Potter ice mine phenomenon.

If a seasonal reversal of underground air currents is to be invoked as an explanation, his diagrams introduced to illustrate this had better be inverted. Every "freezing cave" that has been represented in vertical section shows the more remote recesses of the cave lower than the mouth, and the more nearly vertical the circulation of the air is in consequence of this, the better the conditions for ice accumulation.

This may be illustrated by the conditions which prevail in a "freezing cave" near Gap Creek, Wayne Co., Ky., visited in August, 1898, by the author of this criticism. The cave is in the nature of a vertical sink, the opening of which is situated on the top of a Knob, called "mountain" in that section. The top is about 1,260 feet above sea level (220 above the drainage at the base). Descent into this cave was made by means of rough ladders. Various channels ramify from the main body of the sink, mainly downward. The "mountain" which consists of Mammoth Cave Limestone capped by a thin coping of Kaskaskia Sandstone, appears to be honeycombed with subterranean passages.

Into these passages the cold air tends to descend in winter and from them to rise in summer, due to changes in relative density conditions of the internal and external atmosphere. It appeared also to the writer (and this is the only contribution he wishes to offer to the explanation of ice caves) that the descent of the water through the underground passages during the winter, when this region has its abundant rains, would aid in the intake of cold air at the mouth of the sink somewhat after the manner of a Sprengle pump, and hence would contribute to the thorough refrigeration of the mountain or knob. This agency would operate with little force in summer, when the stage of cave waters is low.

We did not find that the inhabitants in the neighborhood of this Gap Creek ice cave attributed any of the accumulation of ice in it to the summer months, and while it is not impossible in accordance with the theory usually advocated for the explanation of such accumulation, that it might continue after freezing temperatures had disappeared on the outside, there is no indication that this condition of affairs has persisted into the summer, either in the case of this or of any other genuine "glaciere." The result of all actual investigation thus far is in support of this negative. Mr. Andrews fails to offer any first-hand observation in favor of his contention, for by his own statement his visit was made to the "ice mine" in the *spring*. His belief in *summer* accumulation still rests on hearsay evidence.

In view of the fact that such phenomena as we have been here discussing are by no means uncommon (Balch in his work, "Glaciers or Freezing Caverns," cited and quoted from by Mr. Andrews, lists some three hundred instances) it would appear that the subject is important enough to deserve treatment in our text-books on physical geography, where it would appropriately come up under the head of "caverns."

KENTUCKY STATE UNIVERSITY,  
LEXINGTON

## A HUMAN MONSTROSITY

ON May 1, 1912, at Fayette, Missouri, was born a female child (colored) having two heads and three arms. The monstrosity was still-born, but had apparently completed its intra-uterine development. It weighed about fourteen pounds.

The legs are two in number, properly placed, and perfectly normal. The trunk as seen from without is fully developed. Posteriorly it is entirely normal, but the breadth increases considerably toward the anterior end. The chest region is at least one half again as broad as it should be. Other than is suggested by the breadth of the chest, however, there are no signs of duplicity in the trunk. The breasts are two in number and far separated, being normally placed with reference to the sides. The spinal column is single and central as far as can be determined without dissection.

Three arms are present. Two show no signs of irregularity either in position or structure. The third is somewhat dwarfed, and is located on a level with the two normal arms and midway between them. It extends upward and backward, and is attached to an irregularly developed scapula resting between the normal ones. The structure of this third arm and its hand is quite abnormal. Both upper and lower arm bones are present, but reduced in size. The wrist bones are not regular or at least do not permit of normal movement. The bones of the hand are not all present, there being only the metacarpals and phalanges of the thumb and first two fingers. The distal segment in each case bears a thickened claw-like nail.

The most striking feature of this monstrosity is its two heads. Each is set at a slight angle with the general axis of the body, and rests close beside, but not crowding, the other. As far as can be observed, there is no abnormality of any sort in connection with these heads except for the position.

There are many problems of scientific interest suggested by this specimen and no doubt

many facts of interest and importance will be brought to light upon its dissection.

## THE OMAHA TRIBE

A REVIEW of "The Omaha Tribe," published in *SCIENCE*, June 13, 1913, calls for a few words from the authors, notwithstanding their disinclination to respond to a criticism which in some parts sounds more like vituperation. The opening sentences of the reviewer sound the keynote of his whole effort. He says:

The most obvious thing about this monograph is the authors' well-nigh complete neglect of the work of their predecessors. It is their avowed purpose (p. 30) to borrow nothing from other observers and to present "only original material gathered directly from the native people." Apart from any consideration of historical justice this principle is unjustifiable from the standpoint of the student.

Now, the paragraph in the preface in the work from which the above is quoted, reads as follows:

When these studies were begun nothing had been published on the Omaha tribe except short accounts by passing travelers or comments made by government officials. None of these writers had sought to penetrate below the external aspects of Indian life in search of the ideals or belief which animated the acts of the natives. In the account here offered nothing has been borrowed from other observers, only original material gathered directly from the native people has been used and the writer has striven to make, so far as possible, the Omaha his own interpreter.

By comparison of the two quotations it will be readily seen that the context has been willfully disjointed and that a segregated part of it was used as if it were the whole, an unjustified and unscholarly procedure.

The plan and purpose of the authors was to present the results of independent and original investigations on the Omaha, extending for over thirty years, and, as stated on p. 30, to avoid the criticism of other writers. The final adoption of this plan was due in a large degree to the regard which the authors felt for

the late Rev. J. O. Dorsey. They honored his personal character and his conscientious efforts, and preferred silence to the unwelcome task of pointing out the numerous errors throughout his work when he was no longer living to rectify them. Had Mr. Dorsey continued the study of the Omaha language and so perfected his knowledge of it he would have been better able to understand the meaning of the institutions and ideals of the tribe as they were explained to him in the native tongue. Regrettably his imperfect knowledge of the language, as can readily be seen in his Omaha texts, accounts for misconceptions that now appear in his writings.

It is with regret that the authors are now obliged to break the silence which they would have preferred to maintain. The misconceptions of Mr. Dorsey, cited by the reviewer, they corrected in the interest of truth, but without caring to detract from the credit due to the deserving author. Their competency to do so comes from the long and careful study of the tribal institutions and the beliefs on which they were founded, made in conjunction with practically all those men of the tribe who by position and ability were qualified to explain and to interpret tribal life and thought, and also to point out the differences between teachings that were to be taken literally and those which were symbolic in form and character.

The unusual advantages under which the monograph was prepared are indicated in the foreword (p. 30). One of the authors is not only himself an Omaha and well versed in his native language, but is equipped with a knowledge of English, so that niceties of the meaning and of the usage of words are made clear. In consequence of these facts and conditions it was in the power of the authors to state that among the Omaha tribe there was no belief that the ancestors of the people were animals and that at death men returned to the animals from which they sprang.

It would take too much space to reply to all the animadversions and innuendos of the would-be reviewer, nor would any good purpose thereby be served.

FRANCIS LA FLESCHE

# SCIENTIFIC BOOKS

*Éloges académiques et divers. Volume publié par le comité du jubilé scientifique de M. Gaston Darboux.* By GASTON DARBOUT. Paris, A. Hermann & Fils. 1912. Pp. 525 + 4 + portrait. Price, 5 francs.

Jean Gaston Darboux, most eminent of living geometers, was born at Nîmes, France, April 13, 1842. His scientific career may be said to have begun with his entry into the École Normale Supérieure in 1861. To commemorate the fiftieth anniversary of this event<sup>1</sup> it was proposed early in 1911, by a large international group of his mathematical co-workers, friends and former pupils (Professor Hale, of Mount Wilson Observatory, and Professor Hancock, of Cincinnati, were the American representatives), to present to Professor Darboux a gold medal bearing his portrait, and an appropriate address signed by the participants. All mathematicians were invited to share in rendering this honor to Professor Darboux. The response was so generous, the committee was enabled not only to have the eminent artist M. Vernon execute the medal but also to publish a memorial volume. This volume contains a full report of the commemorative proceedings which took place at the Sorbonne, January 21, 1912; Lippmann, Appell, Poincaré, Picard, Volterra, were among the speakers. It also contains 6 éloges historiques (pages 1-306) which Darboux as secrétaire perpétuel delivered before the Academy of Sciences of the Institut after his election in 1900. And finally, we find a dozen of his miscellaneous addresses (pages 307-440) among which mention may be made of that on "The Unity of Science," delivered at St. Louis in 1904, and that on "Fulton and the Academy of Science," delivered in 1909.

The volume is of particular interest to the scientist because of the most attractive style

<sup>1</sup>Curiously enough the letter sent out by the international committee stated that the jubilee of service<sup>2</sup> as a teacher in the system of public instruction in France was to be celebrated. This error is perpetuated on page 443 of the memorial volume to be presently referred to. As a matter of fact, Darboux is even now a year or so short of such a period of service.

of the éloges historiques here collected with annotations from volumes of the *Mémoires de l'Académie des Sciences de l'Institut de France*. Nowhere else are such extended accounts of the scientific careers of Bertrand (pages 1-60), Perrier (pages 61-115), Hermite (pages 116-172), D'Abbadie (pages 173-217), and Meusnier (pages 218-262) to be found.

Joseph Louis François Bertrand (1822-1900) was one of that remarkable group of mathematicians—among them, Poincaré, Poisson, Cauchy, Poncelet, Chasles, Lamé, Le Verrier, Liouville, Halphen, Hermite, Poincaré—who were, at least in part, the product of instruction at the École Polytechnique. A child prodigy and boy not to be bound down by the ordinary routine of the lycée he was nevertheless bachelier, licenciée and docteur ès science when 17 years of age—the youngest doctor of science whom France has ever produced. He then took the entrance examinations for the École Polytechnique. Bertrand has left us some details; Bourdon and Auguste Comte were the examiners:

J'ai le souvenir de l'étonnement de M. Bourdon qui, sachant que j'étais docteur ès sciences, m'avait fait un examen difficile. A la suite de je ne sais quelle réponse, il me dit: "Vous n'avez donc jamais ouvert une table de logarithmes?" Je lui répondis: Non, Monsieur, jamais." Il prit cela pour une impertinence; c'était la pure vérité. Je n'avais fait aucun, devoir scientifique ou littéraire, jamais aucun calcul demandé par aucun maître.

Bertrand then continues:

A l'École Polytechnique, j'étais un problème pour mes camarades. Reçu le premier et gardant le premier rang dans toutes les épreuves, je les étonnais de temps en temps par une ignorance scandaleuse sur des notions qu'on enseigne en septième. Beaucoup d'entre eux croyaient à une ignorance affectée; j'en étais très haïeux au contraire. J'ignorais complètement, par exemple, quelle sorte de mots les grammairiens désignent par le terme d'adverbes.

Bertrand became "répétiteur adjoint d'analyse" at the École Polytechnique in 1844 and professor of analysis in 1856. This position he held till, by reason of the legal age

limit, he was retired in 1895, after 51 years of service. On Bertrand, as well as on Poincaré in more recent times, was bestowed the supreme honor which France has in her gift for the élite of her scientists, namely, of election to both the Académie des Sciences (1856) and the Académie Française (1884) of the Institut.

For an account of Bertrand's researches in geometry, analysis, rational mechanics and physics, and of his text-books so popular in secondary education, reference must be made to Darboux's memoir. One may here also find a sketch of his family life and of his personal characteristics.

François Perrier (1833-1888), another graduate of the École Polytechnique, was employed for nearly a score of years by the general army staff, before he became a chief of the geodetic survey and professor of geodesy in the Ecole de Guerre, Paris. His extensive scientific work was in the field of geodesy.

Charles Hermite (1822-1901) at the time of his death was ranked first among French mathematicians. It was in connection with algebra and arithmetic that he was essentially inventor and creator; most notable were his contributions to elliptic and Abelian functions, algebraic forms and the theory of numbers. Through his proof of the transcendence of  $e$  he may well share with Lindemann (who employed very similar methods in discussing the transcendence of  $\pi$ ) the honor of settling the problem of the squaring of the circle, which had been handed down through the centuries. All these topics and Hermite's career, as professor at the École Polytechnique and at the Sorbonne, as academician, as friend of mathematicians scattered all over the world—are treated at length by Darboux.<sup>2</sup>

Antoine Thompson d'Abbadie (1810-1897)

<sup>2</sup>Disciples of Francis Galton will surely find material of interest in studying hereditary traits of the families of some French mathematicians. For Bertrand was a nephew of Duhamel. Emile Picard and Paul Appell are nephews (the latter by marriage) of Bertrand. Pierre Bouteux is a nephew of Poincaré. Picard's wife was Hermite's daughter and Borel married a daughter of Appell.

was by birth an Irishman. His father, who was descended from an ancient French family, left his native land just before the Revolution and emigrated to Ireland, where he married a Miss Thompson. About 1820 they returned to France with their six children who had been born in Ireland. Two of the children, the brothers, Antoine and Arnaud, became scientists and performed much of their scientific exploration together in Abyssinia and Ethiopia. Antoine was chief of the Venus expedition to Hayti in 1882. Exploration, seismology, geodesy, meteorology, astronomy, claimed his attention at different periods of his life. His principal published work was the monumental "Géodésie de la haute Ethiopie" (1873), which appeared shortly after his election to the Academy of Sciences.

General Jean Baptiste Marie Charles Meusnier de Laplace was born at Tours in 1754, and died at Mayence in 1793, as the result of wounds received in battle. Although thus cut off at the early age of 39 "il laissait" to quote the words of one of his friends, "des traces brillantes d'un intelligence d'élite secondée par un zèle infatigable."

His single memoir in pure mathematics was written just as he was leaving the École Polytechnique and contains a complete theory of the curvature of surfaces<sup>3</sup> from an entirely different point of view from that which Euler illuminated in 1763.<sup>4</sup> When Meusnier's memoir was presented to the Institut in 1776 it created a sensation (d'Alembert exclaimed, "Meusnier commence comme je finis"); and although only 22 years of age he was immedi-

<sup>3</sup>"Mémoire sur la courbure des Surfaces," *Savants étrangers*, t. X., 1785, pp. 477-510. It is this memoir which contains the famous theorem concerning the curvature of oblique sections of surfaces, with which Meusnier's name is always associated. English writers and the American historian Cajori incorrectly write Meusnier's name without the s.

<sup>4</sup>"Recherches sur la courbure des Surfaces," *Mémoires de l'Acad. d. sc. de Berlin*, [t. XVI.] (1760), 1767, pp. 119-143 + 2 Taf. A memoir with this title was presented to the academy by C. G. J. Jacobi on September 8, 1763.

ately elected a correspondent of the Academy of Sciences. While connected with the army during the next few years, Meusnier constructed a machine for the distillation of sea water and the extraordinary results, in connection with both the theory and practise of aerostation, which he presented to the Academy in 1784, brought about his election as academicien.

It was in 1783 that Lavoisier and Laplace maintained before the Institut that the "element" water was formed by the combustion of hydrogen in oxygen. But some doubt existed as to the conclusions. This doubt was forever removed a year later, through experiment inspired by the genius of Meusnier. The subject was presented to the Academy in a "Mémoire . . . par MM. Meusnier et Lavoisier."

R. C. ARCHIBALD

BROWN UNIVERSITY,  
PROVIDENCE, R. I.

*Color Standards and Nomenclature.* By ROBERT RIDGWAY, M.S., C.M.Z.S., etc.; Curator of the Division of Birds, U. S. National Museum. Pp. iii + 44, with 53 plates containing illustrations of 1,115 named colors, and providing a system of nomenclature permitting the definite location and designation of over 4,000 colors. Published by the author, Washington, D. C. Press work by A. Hoen & Co., Baltimore.

This work is a conspicuous example of that devotion to science which has led a few men to give the better part of their lives to the accomplishment of some important task, their hope of reward being little more than the satisfaction of having finished a work that will serve to advance science, and thus contribute to the welfare of mankind. More than twenty years ago the author began the attempt to supply a practical means of identifying the color of natural objects, so that this important property of these objects might be used with some degree of precision in identifying them. The task has been an enormous one, involving much pioneering in a little understood field of science. Many important problems had to be solved before the work

reached the final stages, and a vast amount of work had to be done over and over again as advances were made. The manner in which the more important of these problems have been met is set forth below.

This book is, of course, not the first attempt that has been made to supply standards of color. Ridgway himself had made an earlier attempt.<sup>1</sup> On this subject the author, in his preface, remarks: "Many works on the subject of color have been published, but most of them are purely technical, and pertain to the physics of color, the painter's needs, or to some particular art or industry alone, or in other ways are unsuited for the use of the zoologist, the botanist, the pathologist or the mineralogist; and the comparatively few works on color intended specially for naturalists have all failed to meet the requirements, either because of an insufficient number of color samples, lack of names or other means of easy identification or designation, or faulty selection and classification of the colors chosen for illustration."

The scheme of classification used is essentially that suggested by Professor J. H. Pillsbury.<sup>2</sup> The key to the arrangement of colors in this scheme is the solar spectrum, augmented by adding to the violet end of the spectrum the hues obtained by mixing violet and red in various proportions by means of the Maxwell color disks.<sup>3</sup>

In determining the number of color stand-

<sup>1</sup>"A Nomenclature of Colors for Naturalists," etc., 1886.

<sup>2</sup>See SCIENCE, June 9, 1893; also *Nature*, Vol. LII, No. 1347, August 22, 1895, pp. 390-402.

<sup>3</sup>If a wheel made up of sectors of different color be rapidly revolved on its axis the various colors will appear to blend into a single color. This is the principle of the Maxwell color disks. Throughout this review when reference is made to the mixing of colors what is meant is the blending of colors produced on a rapidly revolving Maxwell disk having its sectors differently colored. In this sense we may with propriety speak of the blending, say, of black and red as the mixing of these two colors, using the term color in its broadest sense. The mixing of pigments is a different thing, and is not here referred to.

ards to be used the first problem was to determine the number of segments into which the original fundamental series should be broken. It is both impracticable and unnecessary to break this continuous series into the more than one thousand hues that are recognizably different to the normal eye. On the other hand, the number of segments must be sufficiently large that the gaps between them may be small enough to serve the practical purpose of identifying colors. On this point the author says: "Distinctions of hue appreciable to the normal eye are so very numerous that the criterion of convenience and practicability must determine the number of segments into which the ideal chromatic scale or circle<sup>4</sup> may be divided in order to best serve the purpose in view. Careful experiment seems to have demonstrated that thirty-six is the practicable limit,<sup>5</sup> and accordingly that number has been adopted."

As far as possible the gaps between each successive pair of these 36 elements of the fundamental series are in each case the same in amount of visual color difference. The scheme of nomenclature adopted provides for an additional color in each of these gaps, so that the fundamental series really consists of 72 named (or rather symbolized) colors, though only 36 are given on the color plates.

The fundamental series of colors thus obtained is modified in three different ways in order to cover the whole range of color variation. Each of these modifications produces a continuous series, which we may call a secondary series. Each of these secondary series begins with the fundamental series, either pure or as modified in a previous secondary

<sup>4</sup>The addition of the hues obtained by various mixtures of violet and red renders the fundamental series a repeating one, and the various hues of which it is composed may hence be arranged in a circle in which there is at all points a gradual change of hue in passing from one primary spectrum color to another. (Footnote by the reviewer.)

<sup>5</sup>"That is to say, the practical limit for pictorial representation of the colors in their various modifications." (Footnote of the author.)

series, and ends with either white, black or neutral gray, according to the character of the modification under consideration. The nature of these secondary series will be understood from the details that follow.

Neutral gray is defined by the author as "being the gray resulting from mixture (on the color wheel) of the three primary colors (red 32, green 42, violet 26 per cent., which in relative darkness equals black 79.5, white 20.5 per cent.)." It may also be described roughly as follows: If by means of a white and a black disk on the color wheel a series of grays be prepared extending from white to black, the visual difference between each of the successive elements of the series being the same, the middle member of this series would be neutral gray. In other words, and roughly speaking, neutral gray is optically half way between white and black.\*

The first of the three modifications of the fundamental series above mentioned consists of mixing the colors of the fundamental series with neutral gray. This produces a continuous series of "broken," or dull, colors. Since it is manifestly impossible to illustrate on the color plates every infinitesimal element of such a series, it becomes necessary to choose certain points in such series as standards. This choice is based on considerations similar to those involved in breaking up the original fundamental series into segments. Five different admixtures of neutral gray were used, giving five series of broken colors. The elements of the fundamental series are designated in the scheme of nomenclature adopted by the cardinal numerals from 1 to 72, only those designated by the odd numbers being illustrated on the color plates. The first series of broken colors, which are obtained from the fundamental series by the admixture of 32 per cent. of neutral gray, are designated by the primed numbers from 1' to 71'. The second series of broken colors contain 58 per cent. of neutral gray, and are designated as 1'' to 71''. The third contains 77 per cent. of neutral gray,

and are designated by the numbers 1''' to 69'''. The fourth, 90 per cent., and designated as 1'''' to 69'''. The fifth, 95.5 per cent., designated as 1''''' to 67'''''.

The fundamental series and the five series of broken colors are represented on the color plates by 150 color specimens. These are arranged in sequence, beginning with red of the fundamental series, and running through the spectrum six times. They form a horizontal line crossing each plate in the middle of the page, and constitute the middle elements of vertical series extending above and below them as follows:

Extending upward from each of these 150 color specimens is a series of "tints" of that particular color. These tints are obtained by mixing each of the 150 colors mentioned with white. Three tints of each color are shown, the first being obtained by mixing with the original colors of the series 9.5 per cent. of white, the second by the admixture of 22.5 and the third of 45 per cent. of white. Above the last tint in each vertical series is a specimen of white.

Extending downward from each of the 150 middle elements described above is a series of "shades" of these elements. The first of these shades is obtained in each case by the admixture of 45 per cent. of black with the original color of the middle series. The second shade contains 70.5 per cent. of black, and the third 87.5 per cent. At the bottom of each vertical column is a specimen of black. For each of the 150 elements obtained from the fundamental series and the five series of broken colors obtained directly from it by the admixture of neutral gray we therefore have a vertical series of shades and tints of that color. Each vertical series extends from white to black, the middle point being one of the 150 middle elements of the scheme of classification. This arrangement of the colors greatly facilitates the comparison of any object with the 1,115 color standards illustrated in the color plates with a view to determining and recording its color.

The system of nomenclature used by the author has already been partially detailed

\* Some authorities use this term to mean gray of any shade or tint provided it shows no spectrum color.

above. It is the excellent system of identifying each color variation by means of symbols which serve to show the location of the color in the scheme of classification that is the most distinctive and original feature of the work. As stated above, each of the 36 segments of the fundamental series is designated by the odd numbers 1, 3, 5, etc., to 71, the even numbers being reserved for colors intermediate between them. These same numbers modified by the use of primes are used to designate the same colors modified by the admixture of neutral gray. Thus the color designated as 27''' is number 27 of the fundamental series weakened by the admixture of 77 per cent. of neutral gray (third series of broken colors).

The tints of any color are designated by the number of the color with the addition of one of the letters a, b, c, d, e, f or g. The three tints of each color illustrated on the plates are designated by the letters b, d and f, the other letters being reserved for tints intermediate between those of the specimens in the book. The shades of a color are similarly designated by the number followed by one of the letters h to n. Thus, 35'' i denotes the thirty-fifth segment of the fundamental series diluted as shown in the second series of broken colors, and further reduced by the admixture of 45 per cent. of black.

The system thus provides a means of designating not only each of the 1,115 specimens of color given in the plates, but all kinds of intermediates between them, the total exceeding 4,000 color variations. The magnitude of this task will be appreciated when it is remembered that in the author's previous book the number of colors named and illustrated was only 186, while in Milton Bradley's excellent little treatise on elementary color there are only 126.

The problem of choosing just what hues, tints, shades and broken colors should be represented in the color plates presents many practical difficulties. The simplest phase of this problem is that of choosing the particular spectrum hues to be designated by the simple names red, orange, yellow, green, blue and

violet. The authorities are by no means agreed as to just what part of the spectrum is the reddest part of the red, the greenest part of the green, etc. Thus the red of ten different authors varies from 644 to  $703 \times 10^{-7}$  cm. in wave-length. Most of the other colors vary as much according to different authorities. Each author is a law unto himself in such matters. This is one of the reasons why any system of color standards which will serve the main purpose of such standards, namely, that of identifying the actual colors met with in nature and in the arts, would be eagerly adopted by naturalists, as well as by those who find need of color standards in the arts.

A much more important difficulty arises from the fact that certain hues of the fundamental series require more elements than others in the series of tones between white and black in order to make the optical intervals between the tones chosen as standards equal in the different series of tones. The author has chosen to represent three tints and three shades of each of the pure colors. This gives a series of seven elements in each series of tones. Except in the yellows this seems to be very satisfactory, but the eye can distinguish such small differences of tone in this part of the spectrum that a larger number of elements in the series of tones would have been helpful. In the yellows and greens there is also a considerable optical interval between the darkest shade (containing 95.5 per cent. of black) and the adjacent samples of black.

The fact that in the series of broken colors the optical intervals between the adjacent hues are less evident than in the full colors also gives rise to a number of practical difficulties in determining just what elements to drop out in order to make the intervals of suitable magnitude and still cover the range of color variation in a satisfactory manner. None are omitted in the first and second series of broken colors, but in the third and fourth each alternate hue is omitted, while the fifth series contains only the six hues ordinarily designated as the primary spectrum colors, except that yellow-orange replaces orange as

being more nearly intermediate between red and yellow.

The last of the 53 color plates gives two series of tones of gray, one obtained by mixing white and black on the color wheel, the other by mixing lamp black and Chinese white. Plates XXII. and XXIV. are extras, from one of several series made during the progress of the work, given because they show a number of important intermediates of the present series that are very useful. Both these plates fall in the first series of broken colors.

Every one of the 1,115 specimens of color shown on the plates is given a name. The method used in selecting these names is given in considerable detail. An excellent index of color names is given on pages 29 to 40, with references to the corresponding specimens in the plates.

Not the least valuable feature of the book is the list of definitions of color terms on pages 15 to 20. The list of dyes and pigments used in the preparation of the Maxwell disks representing the 36 colors of the fundamental series is given on pages 26 and 27. The text ends with a list of a few of the modern books on the subject which the author found most useful in his work.

It is perhaps too much to say that this monumental work is the final solution of the problem of color standards, but it is doubtful if any one so competent as Ridgway in matters relating to color will in the near future devote a very important portion of his working life to the subject as Ridgway has done. He has certainly produced a *usable* set of standards.

W. J. SPILLMAN

U. S. DEPARTMENT OF AGRICULTURE

*Microbes and Toxins.* By E. BURNET. Translated by C. BROQUET and W. M. SCOTT. G. P. Putnam's Sons. 1912.

When Professor Metchnikoff was asked by the publishers of the Bibliothèque de Philosophie Scientifique to prepare for that library a book on microbes and toxins he turned the task over to one of his younger colleagues,

Dr. Etienne Burnet. An English translation has promptly been prepared and makes a volume of some 300 pages. There are four introductory chapters—on the carbon and nitrogen cycles, on the presence of microbes on the surfaces of the human body, on the morphology, and on the physiology of the microbes—and a concluding chapter on chemical remedies for microbial disease (sleeping sickness and syphilis). The other ten chapters forming the bulk of the book deal directly with the problems of infection and immunity.

The book is a little difficult to place. According to Professor Metchnikoff's preface it appears to be intended for general reading. "It is time," he says "for bacteriological science to leave the laboratory and the lecture theater and to take its place before the great public, in order that its benefits may receive the widest and readiest application." It takes a mature mind and a special gift, however, to produce a really popular and yet valuable book upon a technical subject. The present volume is crammed with minute details and discussion of controversial points and seems to the reviewer quite unsuited for the general public. Even for a student's text-book, there is more detail than is desirable. On the other hand, the treatment is by no means sufficiently full and complete to serve as a reliable work of reference for the advanced worker.

Its greatest value perhaps lies in the fact that it presents very fairly the position of the Pasteur Institute headed by Professor Metchnikoff; and the important part played by this school in the development of our knowledge of immunity makes such a "brief," if it may be called so, a valuable contribution to the history of bacteriology. The problems of intestinal bacteriotherapy in Chapter II., of phagocytosis in Chapters VI. and X., and of the mechanism of immunity in Chapter XI., for example, are of special interest.

The view is of course always that of Professor Metchnikoff and his associates rather than a well-rounded presentation of generally accepted opinion; and doubtful points are often dismissed with what one is tempted to

characterize as truly Gallic dogmatism. In regard to the relative importance of humoral and phagocytic factors in immunity statements of the most sweeping nature are made. So we read on page 205: "Are the opsonins substances or properties new and unknown before Wright's researches? Numerous experiments ascribe to the opsonins of normal serum the same properties as characterize the complement. They are products of the leucocytes." And again on page 227: "There are only two 'theories,' that of Ehrlich and that of Bordet, which, with their conjectures, their uncertainty, their attempts at explanation, and their continual state of incompleteness, are striving to round off the positive doctrine, the expression of undoubted facts, namely, phagocytosis." "It is no way of recognizing the capital importance of phagocytosis to admit that anti bodies and other humoral properties are produced by the phagocytes. The essential fact is the destruction of the microbes by incorporation and digestion. Extraphagocytic destruction is so much an exceptional case that it can not even be brought in as opposition."

The illustrations are for the most part crude line drawings of the type found only in French texts. The English translation is somewhat unfortunate, abounding in constructions like the following (from p. 171): "To prepare an anti-endotoxin, as in the prepara-

tion of an antitoxin, it is necessary to inject several times into an animal, for example, the horse, the toxic substance, in this case the bacterial bodies, entire or broken up"; so that the reader is almost reminded of the fate of the famous jumping frog after his translation into French and back again.

C.-E. A. WINSLOW

### SPECIAL ARTICLES

#### A THIRD GROUP OF LINKED GENES IN *DROSOPHILA AMPELOPHILA*

THE existence of a group of sex-linked genes in *Drosophila ampelophila* which are linked to each other in different degrees has been demonstrated by Morgan in numerous papers ('10, '11, '12) and by Sturtevant ('13). The fact that the black and vestigial factors, which are not sex-linked, are linked to each other, was reported by Morgan and Lynch ('12) and by Morgan ('12), and these genes were considered as lying in the "second chromosome." The present paper presents evidence showing the existence of still another group of genes, which are located in the "third chromosome."

The pink-eyed fly, first described by Morgan ('11), has been shown (Morgan, '11, '12) to behave as an ordinary Mendelian recessive to the normal red. That this factor is independent of those in the second chromosome is shown by the following experiments:

Red black ♀	⇒	red gray ♂ and ♀ ⇒	{	red gray	113
×				red black	52
Pink gray ♂	⇒			pink gray	47
				pink black	22
Red gray ♀	⇒	red gray ♂ and ♀ ⇒	{	red gray	279
×				red black	96
Pink black ♂	⇒			pink gray	107
				pink black	40
F <sub>1</sub> red gray ♀ from above	⇒		{	red gray	96
×				red black	111
Pink black ♂	⇒			pink gray	67
				pink black	77
Vestigial red ♀	⇒	long red ♂ and ♀ ⇒	{	long red	717
×				long pink	268
Long pink ♂	⇒			vestigial red	136
				vestigial pink	50

Except for disturbances due to differences in viability these are obviously 9:3:3:1 ratios, except the third, which is 1:1:1:1, as expected. Evidently pink is not linked either to black or to vestigial.

In the balloon-winged stock (see Morgan, '11) there appeared a very dark mutant, which has been named ebony. This fly is darker and more shiny than the black fly, and has a slightly greenish, smoky color when young. It behaves as a simple Mendelian recessive to the normal gray color, though the heterozygous form is often somewhat darker than the wild fly. The females of this race are often sterile, and seldom produce many offspring, but the males breed freely when mated with other females, and produce many offspring. That the gene concerned is not in the second chromosome is indicated by the following experiment:

Vestigial gray ♀	⇒	long gray ♂ and ♀ ⇒	long gray	268
×			long ebony	79
	⇒		vestigial gray	94
Long ebony ♂	⇒		vestigial ebony	24

This is a simple 9:3:3:1 ratio, except that the viability of the ebones is not quite as good as that of the grays. Ebony has also been shown to be independent of two other wing factors in the second chromosome—curved and balloon.

When pink-eyed flies were crossed to those with ebony body color, the following result was obtained:

Gray pink	⇒	gray red ⇒	gray red	3764
×			gray pink	1369
	⇒		ebony red	1112
Ebony red	⇒		ebony pink	0

This count includes a few  $F_2$  flies derived from  $F_2$  red grays mated together, but also includes large numbers of  $F_2$ 's from each of the reciprocal crosses—ebony ♀ × pink ♂ and pink ♀ × ebony ♂. In the later generations from these crosses the writer was able to obtain a few ebony pink flies, and a pure stock of this combination was then made up. When

these flies were used for "coupling" experiments the result was as follows:

Ebony pink	⇒	gray red ⇒	gray red	272
×			gray pink	12
	⇒		ebony red	10
Gray red	⇒		ebony pink	65

The result indicates that the two genes involved are really linked in the ordinary sense. In order to get more exact data doubly heterozygous flies have been crossed to double recessives (ebony pink). Owing to the difficulty of breeding ebony females it has not yet been possible to make any extensive tests of the amount of crossing over in males, but the 88 flies so far raised from doubly heterozygous males by ebony pink females have none of them been cross-overs. Similar tests of doubly heterozygous females have disclosed the existence of much variability in the amount of crossing over, the extreme values

so far obtained being about 1 per cent., on the one hand, and about 27 per cent., on the other. This matter is being further investigated, and it seems probable, from results already obtained, that external conditions play a large part in it. The detailed counts are reserved until this side of the question is more thoroughly worked out, but the totals are given below, because they show beyond question that linkage occurs. When females that showed "coupling" (in Bateson's ('06) sense)—i. e., in which red and gray, pink and ebony were linked—were tested by mating to ebony pink males, the result was as follows:

Gray red (heterozygous) ♀	⇒	gray red	.880
×		gray pink	.86
	⇒	ebony red	.65
Ebony pink ♂	⇒	ebony pink	.691

Tests of females showing Batesonian "repulsion" (having red linked with ebony, pink with gray—Bateson and Punnett, '11) gave the following result:

Gray red (heterozygous) ♀		gray red 3
×		gray pink 601
		ebony red 584
Ebony pink ♂		ebony pink 4

This gives a total of 158 cross-overs out of 2,914 flies, but the absolute proportion is not very significant, because of the variability mentioned above. That rather strong linkage exists, however, there can be no doubt.

COLUMBIA UNIVERSITY,  
May, 1913

### THE NORTH CAROLINA ACADEMY OF SCIENCE

THE twelfth annual meeting of the North Carolina Academy of Science was held in the Science Building at the State Normal College, Greensboro, on Friday and Saturday, April 25 and 26, 1913.

Following a meeting of the executive committee early on Friday afternoon, a session was held for the reading of papers. At the night meeting, after an address of welcome by President J. I. Foust, of the college, President C. S. Brimley, of the academy, delivered his presidential address on "Zoo-geography." Adjournment was then had to the Students' Building, where the members of the academy were given a reception by the faculty of the college.

On Saturday morning the academy met for its annual business meeting. Reports were then made by the secretary-treasurer and the several stated committees. Twelve new members were elected. The finances were shown to be in good shape—all bills being paid, with \$125 in the savings bank. It was noted that Dr. C. W. Stiles, one of our members, had by action of the executive committee been appointed to represent the academy at the Ninth International Zoological Congress at Monaco, March 25-29, 1913.

The following officers were elected for the ensuing year:

*President*—Franklin Sherman, state entomologist, Raleigh.

*Vice-president*—Z. P. Metcalf, professor of entomology, North Carolina Agricultural and Mechanical College, West Raleigh.

*Secretary-treasurer*—E. W. Gudger, professor of biology, State Normal College, Greensboro.

*Additional Members of Executive Committee*—W. C. Coker, professor of botany, University of

North Carolina, Chapel Hill; J. J. Wolfe, professor of biology, Trinity College, Durham; C. S. Brimley, naturalist, Raleigh.

Following the business meeting, the reading of papers was resumed and continued until the program was finished and adjournment had at 1:15 P.M. The attendance was 27 out of a membership of 76. There were 22 papers on the program. Four of these were read by title, one was presented by another member in the absence of the author, and the other 17 were read by their authors in order as called for on the program.

The papers read were as follows:

*Zoo-geography*: C. S. BRIMLEY, Raleigh.

Briefly discusses the primary life areas of the world, which the author believes to be five in number, namely, an Australian, a Neotropical, an Ethiopian, an Indian with the limits usually assigned to them by zoologists, and lastly a Northern Realm, including all of the earth's land surface lying north of the other four. The paper then divides the Northern Realm into three regions, an Arctic, a Eurasian and a North American, and proceeds to divide the North American continent into the usual seven life zones, Arctic, Hudsonian, Canadian, Alleghanian, Upper Austral, Lower Austral and Tropical. The life zones entering the state of North Carolina are then discussed at greater length and found to be four in number, the Canadian, Alleghanian, Upper and Lower Austral. The first is stated to occupy the summits of the mountains above about 4,500 feet, the second that portion of the mountain region lying between 2,500 and 4,500 feet elevation, the third comprising the mountain valleys under 2,500 feet, and the central part of the state lying between the mountains and a line drawn from Weldon to Raleigh, and thence to Charlotte, the fourth including the remainder of the state, namely, all lying south and east of the above-named line. The animals distinctive of these zones are named and certain irregularities and anomalies in distribution are pointed out.

This paper will appear in full in the May issue of the *Journal of the Elisha Mitchell Scientific Society*.

*Will Cells of the Embryo Sea Urchin, when Introduced into the Body of the Adult, become Tissue Cells of the Latter?* H. V. WILSON, University of North Carolina, Chapel Hill.

Plasmodia formed by union of lymph cells were allowed to engulf blastulae, and were grafted on the wound membranes which close in apertures

made in the test of the urchin. The blastulae after certain changes broke up into their constituent cells. In this way dissociated embryonic cells were brought into the midst of a developing membrane, having a very simple histological character. In the actual experiments a very large proportion of the embryonic cells underwent degeneration. There was some evidence, though by no means convincing, that groups of the smaller cells became part of the developing membrane.

*Alternation of Generations in Padina:* JAS. J. WOLFE, Trinity College, Durham.

While at work on the life history of *Padina* at the Fisheries Laboratory at Beaufort it seemed worth while to test the theory of alternation of generations in such plants by the cultural methods devised by Hoyt.<sup>1</sup> Numerous cultures were made during the summer of 1910 and the next—all having but indifferent success. They were repeated in 1912 with somewhat better results. The cultures of tetraspores produced a total of 134 male, 154 female, and no tetrasporic plants. Those from fertilized eggs were somewhat less conclusive. Nevertheless, the evidence from cultures strongly supports the view that in *Padina* there is a real alternation of sporophyte with gametophyte.

*Gestation in the Nurse Shark, Ginglymostoma cirratum:* E. W. GUDGER, State Normal College, Greensboro, N. C.

A brief description was given of the breeding habits and of some points in the embryology of this shark, which was studied at the laboratory of the Carnegie Institution at Tortugas, Florida, in June and July, 1912. A brief account has been published in the Year Book for 1912 of the Carnegie Institution of Washington, Department of Marine Biology, pages 148–150.

*Hybridization Experiments on Frogs:* W. C. GEORGE, University of North Carolina, Chapel Hill.

*Chorophilus n. feriarum* was crossed with *Acris gryllus*. About half of the eggs segmented. (In the pure *Chorophilus* control practically all the eggs segmented.) The development was markedly retarded and was abnormal. The conspicuous abnormalities concerned the behavior of the yolk pole. Thus segmentation at this pole was not perfect, and the closure of the blastopore was interfered with in such wise that there developed the well-known abnormal type produced in so many ways, characterized by a large blastopore area and the differentiation of the neural plate.

<sup>1</sup> Bot. Gaz., January, 1910.

*The Toxicity of Cottonseed Meal:* W. A. WITHERS, J. F. BREWSTER, L. F. WILLIAMS and J. W. NOWELL. With the collaboration of R. S. CURTIS and G. A. ROBERTS, North Carolina Experiment Station, West Raleigh.

The authors conclude from experiments, some of which have been published,<sup>1</sup> that the toxicity of cottonseed meal is due to a constituent group of the proteins, probably one containing loosely bound sulphur. They suggest some form of iron as an antidote, having found with Belgian hares that citrate of iron and ammonia (0.7 gm. daily) is effective in overcoming and in preventing cottonseed meal intoxication. Further experiments are in progress with small animals and with swine. Efforts to isolate the toxic substance will be continued.

*Fishing for Sharks in Key West Harbor:* E. W. GUDGER, State Normal College, Greensboro.

In this paper the capture was described of a 7-foot 10-inch male specimen of *Hypoprion brevirostris* and a 10-foot 10-inch female specimen of the tiger shark, *Galeocerdo tigrinus*, in Key West Harbor, in July, 1912. These two fishes not being very well known, it is proposed later to publish careful descriptions with exact measurements.

The jaws of the tiger shark, which were exhibited, measured 1 foot 4 inches straight across, and around the curve of the jaws 1 foot 9 inches. Its stomach contained more than a half barrel of miscellaneous material, including a cow's head (dehorned) minus the lower jaws, the vertebral column of a sheep, the scutes of a green turtle, the bones and feathers of two birds and a lot of tin cans and sea weed. The uteri were dissected, but unfortunately the fish was not in breeding condition.

*A Second Capture of the Whale Shark, Rhineodon typus, in Florida Waters:* E. W. GUDGER, State Normal College, Greensboro.

This paper will be published in full in SCIENCE. For the following papers no abstracts have been received:

## SOCIETIES AND ACADEMIES

### THE ACADEMY OF SCIENCE OF ST. LOUIS

At the meeting of the academy on March 3, Dr. R. J. Terry, of the Washington University Medical School, read his second paper on "The Development of the Cranium in Mammals."

Dr. Terry stated that Weiss's study of the occipital region of embryos of white rats revealed the fact that the dens epistrophei in these animals is composed of two elements, the one generally

recognized as comparable with a centrum for the atlas, the other lying cephalad of this and forming the extremity of the dens. The latter is derived by independent chondrification in the tissue about the notochord cephalad of the atlas and where the former crosses the dorsal surface of the basal plate of the cranium. Weiss regarded this cephalic element as representing the centrum of an occipital vertebra or a proatlas.

The presence of an element in the dens epistrophei of cat embryos has been observed developing cephalad of the component identified as the centrum of the atlas and extending upon the basal plate of the cranium. This component is derived from the mesenchyma which, in the form of a cone traversed by the notochord, extends from the level of the atlas cephalad upon the basal plate and there lies in a deep median groove. Chondrification in this part of the dens occurs later than in that part related to the atlas, but the two processes appear not to be entirely distinct.

At the meeting of April 21 Professor R. A. Hall, of Washington University, stated to the academy that he had succeeded in preparing neutral tri-ammonium citrate in commercial quantities.

Professor Hall described a method in which neutral tri-ammonium citrate was prepared by passing an excess of dry ammonia gas into a well-cooled solution of the water-free citric acid in an anhydrous solvent.<sup>1</sup> The yield is quantitative. Tri-ammonium citrate thus prepared is a stable, white crystalline substance, not hygroscopic and not affected by the CO<sub>2</sub> of the atmosphere. It dissolves readily in water and the freshly-prepared solution is neutral to sensitive litmus, azolitmin, corallin, methyl red, etc. Rigorous analyses of both the ammonia and the citrate content of the salt show it to be the tri-ammonium citrate. Further investigation of its physical-chemical properties is being made.

As the method of preparation is simple and inexpensive and the yield good, it is evident that this means a solution of the difficult problem of the fertilizer chemist in the preparation of neutral ammonium citrate solution for the determination of the insoluble phosphoric acid in fertilizer analysis.

G. O. JAMES,  
*Corresponding Secretary*

<sup>1</sup>This body was first prepared by this method two years ago at the time of the investigation of the conductivity method of preparing neutral ammonium citrate solutions, but a press of other research prevented its analysis and complete identification until the present time.
